Section (1.1): Origin of Partial Differential Equations

(1.1.1) Introduction:

Partial differential equations arise in geometry, physics and applied mathematics when the number of independent variables in the problem under consideration is two or more. Under such a situation, any dependent variable will be a function of more than one variable and hence it possesses not ordinary derivatives with respect to a single variable but partial derivatives with respect to several independent variables.

(1.1.2) Definition Partial Differential Equations (P.D.E.)

An equation containing one or more partial derivatives of an unknown function of two or more independent variables is known as a (P.D.E.).

For examples of partial differential equations we list the following:

1. \[ \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y} = z + xy \]
2. \[ \left( \frac{\partial z}{\partial x} \right)^2 + \frac{\partial^3 z}{\partial y^3} = 2x \left( \frac{\partial z}{\partial y} \right) \]
3. \[ z \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y} = x \]
4. \[ \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} = xyz \]
5. \[ \frac{\partial^2 z}{\partial x^2} = (1 + \frac{\partial z}{\partial y})^2 \]
6. \[ y \left( \frac{\partial z}{\partial x} \right)^2 + \left( \frac{\partial z}{\partial y} \right)^2 = z \left( \frac{\partial z}{\partial y} \right) \]
(1.1.3) **Definition: Order of a Partial Differential Equation (O.P.D.E.)**

The order of a partial differential equation is defined as the order of the highest partial derivative occurring in the partial differential equation.

The equations in examples (1), (3), (4) and (6) are of the first order, (5) is of the second order and (2) is of the third order.

(1.1.4) **Definition: Degree of a Partial Differential Equation (D.P.D.E.)**

The degree of a partial differential equation is the degree of the highest order derivative which occurs in it after the equation has been rationalized, i.e. made free from radicals and fractions so far as derivatives are concerned. In (1.1.2), equations (1), (2), (3) and (4) are of first degree while equations (5) and (6) are of second degree.

(1.1.5) **Definition: Linear and Non-Linear Partial Differential Equations**

A partial differential equation is said to be (Linear) if the dependent variable and its partial derivatives occur only in the first degree and are not multiplied. A partial differential equation which is not linear is called a (non-linear) partial differential equation.
In (1.1.2), equations (1) and (4) are linear while equation (2),(3),(5) and (6) are non-linear.

**(1.1.6) Notations:**

When we consider the case of two independent variables we usually assume them to be $x$ and $y$ and assume $(z)$ to be the dependent variable. We adopt the following notations throughout the study of partial differential equations.

\[ p = \frac{\partial z}{\partial x}, \quad q = \frac{\partial z}{\partial y}, \quad r = \frac{\partial^2 z}{\partial x^2}, \quad s = \frac{\partial^2 z}{\partial x \partial y}, \quad \text{and} \quad t = \frac{\partial^2 z}{\partial y^2} \]

In case there are $n$ independent variables, we take them to be $x_1, x_2, \ldots, x_n$ and $z$ is then regarded as the dependent variable. In this case we use the following notations:

\[ p_1 = \frac{\partial z}{\partial x_1}, \quad p_2 = \frac{\partial z}{\partial x_2}, \ldots, p_n = \frac{\partial z}{\partial x_n} \]

Sometimes the partial differentiations are also denoted by making use of suffixes. Thus we write:

\[ u_x = \frac{\partial u}{\partial x}, \quad u_y = \frac{\partial u}{\partial y}, \quad u_{xx} = \frac{\partial^2 u}{\partial x^2}, \quad u_{yy} = \frac{\partial^2 u}{\partial y^2} \]

and so on.
**Chapter One: Methods of solving partial differential equations**

(1.1.7) **Classification of First Order p.d.es into:** linear, semi-linear, quasi-linear and non-linear equations

*Linear equation:* A first order equation \( f(x, y, z, p, q) = 0 \)

Is known as linear if it is linear in \( p \), \( q \) and \( z \), that is, if given equation is of the form:

\[
P(x, y)p + Q(x, y)q = R(x, y)z + S(x, y)
\]

for example:

1. \( yx^2p + xy^2q = xyz + x^2y^3 \)
2. \( p + q = z + xy \)

are both first order L.P.D.Es

*Semi-linear equation:* A first order p.d.e. \( f(x, y, z, p, q) = 0 \)

Is known as a semi-linear equation, if it is linear in \( p \) and \( q \) and the coefficients of \( p \) and \( q \) are functions of \( x \) and \( y \) only. i.e if the given equation is of the form:

\[
P(x, y)p + Q(x, y)q = R(x, y, z)
\]

for example:

1. \( xyp + x^2yq = x^2y^2z^2 \)
2. \( yp + xq = \frac{x^2y^2}{z^2} \)

are both semi-linear equations

*Quasi-linear equation:* A first order p.d.e. \( f(x, y, z, p, q) = 0 \)

Is known as quasi-linear equation, if it is linear in \( p \) and \( q \). i.e if the given equation is of the form:

\[
P(x, y, z)p + Q(x, y, z)q = R(x, y, z)
\]
Chapter One: Methods of solving partial differential equations

for example:
1. $x^2zp + y^2zq = xy$
2. $(x^2 - yz)p + (y^2 - zx)q = z^2 - xy$
are both quasi-linear equation.

*Non-linear equation:* A first order p.d.e $f(x, y, z, p, q) = 0$ which does not come under the above three types, is known as a non-linear equation.

for example:
1. $p^2 + q^2 = 1$
2. $pq = z$
3. $x^2p^2 + y^2q^2 = z^2$
are all non-linear p.d.e.s.
Section(1.2): Derivation of Partial Differential Equation by the Elimination of Arbitrary Constants

For the given relation \( F(x, y, z, a, b) = 0 \) involving variables \( x, y, z \) and arbitrary constants \( a \) and \( b \), the relation is differentiated partially with respect to independent variables \( x \) and \( y \). Finally arbitrary constants \( a \) and \( b \) are eliminated from the relations

\[
F(x, y, z, a, b) = 0, \quad \frac{\partial F}{\partial x} = 0 \quad \text{and} \quad \frac{\partial F}{\partial y} = 0
\]

The equation free from \( a \) and \( b \) will be the required partial differential equation.

Three situations may arise:

Situation (1):

When the number of arbitrary constants is less than the number of independent variables, then the elimination of arbitrary constants usually gives rise to more than one partial differential equation of order one.

Example: Consider \( z = ax + y \) .............(1)

where \( a \) is the only arbitrary constant and \( x, y \) are two independent variables.

Differentiating (1) partially w.r.t. \( x \), we get

\[
\frac{\partial z}{\partial x} = a \quad .............(2)
\]

Differentiating (1) partially w.r.t. \( y \), we get

\[
\frac{\partial z}{\partial y} = 1 \quad .............(3)
\]
Chapter One: Methods of solving partial differential equations

Elminating abetween (1) and (2) yields

\[ z = x\left(\frac{\partial z}{\partial x}\right) + y \quad \text{............}(4) \]

Since (3) does not contain arbitrary constant, so (3) is also partial diff. equation under consideration thus, we get two p.d.es (3) and (4).

**Situation (2):**

When the number of arbitrary constants is equal to the number of independent variables, then the elimination of arbitrary constants shall give rise to a unique partial diff. eq. of order one.

**Example:** Eliminate a and b from

\[ az + b = a^2 x + y \quad \text{............}(1) \]

Differencing (1) partially w.r.t. x and y, we have

\[ a\left(\frac{\partial z}{\partial x}\right) = a^2 \quad \text{............}(2) \]

\[ a\left(\frac{\partial z}{\partial y}\right) = 1 \quad \text{............}(3) \]

Eliminating a from (2) and (3), we have

\[ \left(\frac{\partial z}{\partial x}\right)\left(\frac{\partial z}{\partial y}\right) = 1 \]

which is the unique p.d.e. of order one.

**Situation (3):**

When the number of arbitrary constants is greater than the number of independent variables. Then the elimination of arbitrary constants leads to a partial differential equation of order usually greater than one.
Example: Eliminate a, b and c from

\[ z = ax + by + cxy \quad \ldots \ldots \ldots \ldots \ldots (1) \]

Differentiating (1) partially w.r.t. x and y we have

\[ \frac{\partial z}{\partial x} = a + cy \quad \ldots \ldots \ldots \ldots \ldots (2) \]
\[ \frac{\partial z}{\partial y} = b + cx \quad \ldots \ldots \ldots \ldots \ldots (3) \]

from (2) and (3)

\[ \frac{\partial^2 z}{\partial x^2} = 0 \quad \frac{\partial^2 z}{\partial y^2} = 0 \quad \ldots \ldots \ldots \ldots \ldots (4) \]

Now, (2) and (3)\( x \frac{\partial z}{\partial x} = ax + cxy \) and

\[ y \frac{\partial z}{\partial y} = by + cxy \]

\[ x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} = ax + by + cxy + cxy \]

from (1) and (5)

\[ x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} = z + xy \frac{\partial^2 y}{\partial x \partial y} \quad \ldots \ldots \ldots \ldots \ldots (6) \]

Thus, we get three p.d.e.s given by (4) and (6) which are all of order two.

... Examples ...

Example1: Find a p.d.e. by eliminating a and b from

\[ z = ax + by + a^2 + b^2 \]

Sol. Given \( z = ax + by + a^2 + b^2 \quad \ldots \ldots \ldots \ldots \ldots (1) \)

differentiating (1) partially with respect to x and y,

we get \( \frac{\partial z}{\partial x} = a \quad \text{and} \quad \frac{\partial z}{\partial y} = b \)
substituting these values of a and b in (1) we see that the arbitrary constants a and b are eliminated and we obtain

\[ z = x \left( \frac{\partial z}{\partial x} \right) + y \left( \frac{\partial z}{\partial y} \right) + \left( \frac{\partial z}{\partial x} \right)^2 + \left( \frac{\partial z}{\partial y} \right)^2 \]

which is required p.d.e.

**Example 2:** Eliminate arbitrary constants a and b from

\[ z = (x - a)^2 + (y - b)^2 \]

to form the p.d.e.

**Sol.** Given \( z = (x - a)^2 + (y - b)^2 \) ...........(1)
differentiating (1) partially with respect to x and y, to get

\[ \frac{\partial z}{\partial x} = 2(x - a) \quad , \quad \frac{\partial z}{\partial y} = 2(y - b) \]

Squaring and adding these equations, we have

\[ \left( \frac{\partial z}{\partial x} \right)^2 + \left( \frac{\partial z}{\partial y} \right)^2 = 4(x - a)^2 + 4(y - b)^2 \]

\[ \left( \frac{\partial z}{\partial x} \right)^2 + \left( \frac{\partial z}{\partial y} \right)^2 = 4[(x - a)^2 + (y - b)^2] \]

\[ \left( \frac{\partial z}{\partial x} \right)^2 + \left( \frac{\partial z}{\partial y} \right)^2 = 4z \quad \text{using (1)} \]

**Example 3:** from p.d.es by eliminating arbitrary constants a and b from the following relations:

(a) \( z = a(x + y) + b \quad \) (b) \( z = ax + by + ab \)
(c) \( z = ax + a^2 y^2 + b \quad \) (d) \( z = (x + a)(y + b) \)

**Sol.** (a) Given \( z = a(x + y) + b \) ...........(1)

Differentiating (1) w.r.t.x and y, we get

\[ \frac{\partial z}{\partial x} = a \quad \frac{\partial z}{\partial y} = a \]
eliminating $a$ between these, we get
\[ \frac{\partial z}{\partial x} = \frac{\partial z}{\partial y} \] which is the required p.d.e.

(b) Try yourself (c) Try yourself (d) Try yourself

... Exercises ...

Ex.(1): Eliminate $a$ and $b$ from $z = axe^y + \frac{1}{2}a^2e^y + b$ to form the partial differential equation.

Ex.(2): Eliminate $h$ and $k$ from the equation $(x - h)^2 + (y - k)^2 + z^2 = \alpha^2$ to form the p.d.e.

Ex.(3): Eliminate $a$ and $b$ from the following equations to form the p.d.es
\[ (a) 2z = \frac{x^2}{a^2} + \frac{y^2}{b^2} \quad (b) 2z = (ax + y)^2 + b(c)\log(az - 1) = x + ay + b \]

Ex.(4): Eliminate the arbitrary constants indicated in brackets from the following equations and form corresponding partial diff. eqs

(1) $z = Ae^{pt}\sin px$, (p and A)
(2) $z = Ae^{-p^2t}\cos px$, (p and A)
(3) $z = ax^3 + by^3$, (a and b)
(4) $4z = \left[ ax + \left( \frac{y}{a} \right) + b \right]^2$, (a and b)
(5) $z = ax^2 + bxy + cy^2$, (a, b, c)

-----------------------------
Section (1.3): Methods for solving linear and non-linear partial differential equations of order one

(1.3.1) **Lagrange's method of solving** \( Pp + Qq = R \), when \( P, Q \) and \( R \) are function of \( x, y, z \).

A quasi-linear partial differential equation of order one is of the form \( Pp + Qq = R \), where \( P, Q \) and \( R \) are function of \( x, y, z \). Such a partial differential equation is known as (Lagrange equation), for example:

\[
\begin{align*}
* \quad xyp + yzq &= zx \\
* \quad (x - y)p + (y - z)q &= z - x
\end{align*}
\]

(1.3.2) **Working Rule for solving** \( Pp + Qq = R \) **by Lagrange's method**

**Step 1.** Put the given linear p.d.e. of the first order in the standard form \( Pp + Qq = R \) ...........(1)

**Step 2.** Write down Lagrange's auxiliary equations for (1) namely

\[
\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} \quad ...........(2)
\]

**Step 3.** Solve (2) by using the method for solving ordinary differential equation of order one. The equation (2) gives three ordinary diff. eqs. every two of them are independent and give a solution.
Let \( u(x, y, z) = a \quad \text{and} \quad v(x, y, z) = b \), then the (general solution) is \( \phi(u, v) = 0 \), where \( \phi \) is an arbitrary function and the complete solution is \( u = \alpha v + \beta \) where \( \alpha, \beta \) are arbitrary constants.

**Ex.1: Solve** \( 2 \frac{\partial z}{\partial x} - 3 \frac{\partial z}{\partial y} = 2x \)

**Sol.** Given \( 2 \frac{\partial z}{\partial x} - 3 \frac{\partial z}{\partial y} = 2x \) \( \quad \ldots \ldots \quad (1) \)

The Lagrange's auxiliary for (1) are

\[
\frac{dx}{2} = \frac{dy}{-3} = \frac{dz}{2x} \quad \ldots \ldots \quad (2)
\]

Taking the first two fractions of (2), we have

\[
\frac{dx}{2} = \frac{dy}{-3} \rightarrow -3dx - 2dy = 0 \quad \ldots \ldots \quad (3)
\]

Integrating (3), \( -3x - 2y = a \) \( \quad \ldots \ldots \quad (4) \)

a being an arbitrary constant

Next, taking the first and the last fractions of (2), we get

\[
\frac{dx}{2} = \frac{dz}{2x} \quad \rightarrow \quad xdx = dz \quad \rightarrow \quad xdx - dz = 0 \quad \ldots \ldots \quad (5)
\]

Integrating (5), \( \frac{x^2}{2} - z = b \) \( \quad \ldots \ldots \quad (6) \)

b being an arbitrary constant

From (4) and (6) the required general solution is

\[
\phi(a, b) = 0 \quad \rightarrow \quad \phi\left(-3x - 2y, \frac{x^2}{2} - z\right) = 0
\]

Where \( \phi \) is an arbitrary function.

**Ex.2: Solve** \( \left(\frac{y^2z}{x}\right)p + xzq = y^2 \)
Chapter One: Methods of solving partial differential equations

Sol. Given \( \left( \frac{y^2z}{x} \right) p + xzq = y^2 \) \…………(1)

The Lagrange's auxiliary equation for (1) are
\[
\frac{dx}{y^2z} = \frac{dy}{xz} = \frac{dz}{y^2} \quad \text{…………(2)}
\]

Taking the first two fractions of (2), we have
\[
x^2zdx = y^2zdy \quad \rightarrow \quad x^2dx - y^2dy = 0 \quad \text{…………(3)}
\]
Integrating (3), \[\frac{x^3}{3} - \frac{y^3}{3} = a \quad \rightarrow \quad x^3 - y^3 = a_1 \quad \text{……(4)}\]
a_1 being an arbitrary constant.

Next, taking the first and the last fractions of (2), we get
\[
xy^2dx = y^2zdz \quad \rightarrow \quad xdx - zdz = 0 \quad \text{…………(5)}
\]
Integrating (5), \[\frac{x^2}{2} - \frac{z^2}{2} = b \quad \rightarrow \quad x^2 - z^2 = b_1 \quad \text{(6)}
\]
b_1 being an arbitrary constant

From (4) and (6) the general solution is
\[
\emptyset(a_1, b_1) = 0 \quad \rightarrow \quad \emptyset(x^3 - y^3, x^2 - z^2) = 0
\]

**Ex.3**: Solve \( x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} + t \frac{\partial z}{\partial t} = xyt \)

Sol. Given \( x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} + t \frac{\partial z}{\partial t} = xyt \) \…………(1)

The Lagrange's auxiliary equation for (1) are
\[
\frac{dx}{x} = \frac{dy}{y} = \frac{dt}{t} = \frac{dz}{xyt} \quad \text{…………(2)}
\]

Taking the first two fractions of (2), we have
\[
\frac{dx}{x} = \frac{dy}{y} \quad \rightarrow \quad \frac{dx}{x} - \frac{dy}{y} = 0 \quad \text{…………(3)}
\]
Integrating (3), \( \ln x - \ln y = \ln a \quad \rightarrow \quad \frac{x}{y} = a \quad \text{……(4)}\)
Taking the second and the third fractions of (2), we get
\[
\frac{dy}{y} = \frac{dt}{t} \quad \rightarrow \quad \frac{dy}{y} - \frac{dt}{t} = 0 \quad \text{.........(5)}
\]

Integrating (5), \(\ln y - \ln t = \ln b \quad \rightarrow \quad \frac{y}{t} = b \quad \text{ .......(6)}

Next, taking the second and the last fractions of (2), we get
\[
\frac{dy}{y} = \frac{dz}{xyt} \quad \rightarrow \quad xtdy - dz = 0 \quad \text{...........(7)}
\]

Substituting (4) and (6) in (7), we get
\[
\frac{a}{b} y^2 dy - dz = 0 \quad \text{ ...........(8)}
\]

Integrating (8), \(\frac{a}{3b} y^3 - z = c \)

Using (4) and (6), \(\frac{1}{3} xyt - z = c \quad \text{ ..........(9)}

Where a, b and c are an arbitrary constant

The general solution is
\[
\phi(a, b, c) = 0 \quad \rightarrow \quad \phi\left(\frac{x}{y}, \frac{y}{t}, \frac{1}{3} xyt - z\right) = 0
\]

\(\phi\) being an arbitrary function.

**Rule:** for any equal fractions, if the sum of the denominators equal to zero, then the sum of the numerators equal to zero also.

Now, Return to the last example depending on the Rule above we will find the constant c.

Multiplying each fraction in Lagrange's auxiliary (2) by \(yt, xt, xy, -3\) respectively, we get the sum of the denominators is
Chapter One: Methods of solving partial differential equations

\[ xyt + xyt + xyt - 3xyt = 0 \quad \ldots \ldots (10) \]

Then the sum of the numerators equal to zero also:

\[ ytdx + xtdy + xydt - 3dz = 0 \rightarrow \quad d(yxt) - 3dz = 0 \quad \ldots \ldots (11) \]

Integrating (11), \[ yxt - 3z = c \quad \ldots \ldots (12) \]

Note that (12) and (9) are the same.

**Ex.4:** Solve \((y - z)p + (z - x)q = x - y\)

Sol. Given \((y - z)p + (z - x)q = x - y \quad \ldots \ldots (1)\)

The Lagrange's auxiliary equations for (1) are

\[ \frac{dx}{y - z} = \frac{dy}{z - x} = \frac{dz}{x - y} \quad \ldots \ldots (2) \]

The sum of the denominators is

\[ y - z + z - x + x - y = 0 \]

Then, the sum of the numerators is equal to zero also, (by Rule)

\[ dx + dy + dz = 0 \quad \ldots \ldots (3) \]

Integrating (3), \[ x + y + z = a \quad \ldots \ldots (4) \]

To find \(b\), multiplying (2) by \(x, y, z\) resp. the sum of the denominators is

\[ x(y - z) + y(z - x) + z(x - y) = xy - xz + yz - xy + zx - yz = 0 \]

Then, the sum of the numerators is equal to zero

\[ xdx + ydy + zdz = 0 \quad \ldots \ldots (5) \]

Integrating (5), \[ \frac{x^2}{2} + \frac{y^2}{2} + \frac{z^2}{2} = b \quad \ldots \ldots (6) \]

Where, \(a\) and \(b\) are arbitrary constants.

The general solution is
\[
\varnothing(a,b) = 0 \rightarrow \varnothing\left(x + y + z, \frac{x^2}{2} + \frac{y^2}{2} + \frac{z^2}{2}\right) = 0
\]

... Exercises ...

Solve the following partial differential equation:

1. \( p \tan x + q \tan y = \tan z \).

2. \( zp = -x \).

3. \( y^2p - xyq = x(z - 2y) \).

4. \( (x^2 + 2y^2)p - xyq = xz \).

5. \( xp + yq = z \).

6. \( (-a + x)p + (-b + y)q = (-c + z) \).

7. \( x^2p + y^2q + z^2 = 0 \).

8. \( yzp + zxq = xy \).

9. \( y^2p + x^2q = x^2y^2z^2 \).

10. \( p - q = \frac{z}{x+y} \)

(1.3.2) The equation of the form \( f(p, q) = 0 \)

Here we consider equations in which \( p \) and \( q \) occur other than in the first degree, that is non-linear equations. To solve the equation \( f(p, q) = 0 \) \( ........(1) \)
Chapter One: Methods of solving partial differential equations

Taking \( p = \text{constant} = a \) \( ...........(2) \)
\( q = \text{constant} = b \) \( ...........(3) \)
Substituting (2),(3) in (1), we get
\[ F(a,b) = 0 \rightarrow b = F_1(a) \quad \text{or} \quad a = F_2(b) \] \( ...........(4) \)
From \( dz = p\,dx + q\,dy \) \( ...........(5) \)
Using (2),(3) \( \rightarrow dz = adx + bdy \) \( ...........(6) \)
Integrating (6), \( z = ax + by + c \) \( ...........(7) \)
Where \( c \) is an arbitrary constant
Substituting (4) in (7) to obtain the complete integral (complete solution)
\[ z = ax + F_1(a)y + c \quad \text{or} \quad z = F_2(b)x + by + c \] \( ...........(8) \)

**Ex.1:** Solve \( p^2 + p = q^2 \)
Sol. \( p^2 + p - q^2 = 0 \) \( ...........(1) \)
The equation (1) of the form \( f(p,q) = 0 \)
Let \( p = a, q = b \)
Substituting in (1)
\[ a^2 + a - b^2 = 0 \rightarrow b^2 = a^2 + a \rightarrow b = \pm \sqrt{a^2 + a} \]
The complete integral is
\[ z = ax + by + c \]
\[ = ax \pm \sqrt{a^2 + ay + c} \]
Where \( c \) is an arbitrary constant.

**Ex.2:** Solve \( pq = k \), where \( k \) is a constant.
Sol. Given that \( pq = k \) \( ...........(1) \)
Chapter One: Methods of solving partial differential equations

Since (1) is of the form \( f(p, q) = 0 \), its solution is
\[
z = ax + by + c \quad \ldots(2)
\]
Let \( p = a \), \( q = b \), substituting in (1), then \( ab = k \rightarrow b = \frac{k}{a} \ldots(3) \)
Putting (3) in (2), to get the complete solution
\[
z = ax + \frac{k}{a} y + c \quad ; c \text{ is an arbitrary constant .}
\]

**Ex.3:** Solve \( \frac{\partial z}{\partial x} - 3 \frac{\partial z}{\partial y} = \left( \frac{\partial z}{\partial y} \right)^3 \)

Sol. Given that \( p - 3q = q^3 \quad \ldots \ldots \ldots \ldots (1) \)
Since (1) is of the form \( f(p, q) = 0 \), then
Let \( p = a \), \( q = b \)
Substituting in (1), \( a - 3b = b^3 \rightarrow a = b^3 + 3b \quad \ldots \ldots \ldots \ldots (2) \)
Putting (2) in the equation \( z = ax + by + c \), we get
\[
z = (b^3 + 3b)x + by + c
\]
Where \( c \) is an arbitrary constant
The equation (3) is the complete integral .

**(1.3.3) The Equation of the form** \( z = px + qy + f(p, q) \)

A first order partial differential equation is said to be of **Clariaut** form if it can be written in the form
\[
z = px + qy + f(p, q) \quad \ldots\ldots(1)
\]
to solve this equation taking \( p = a \), \( q = b \) and substituting in (1), so the complete integral is
\[
z = ax + by + f(a, b) \quad \ldots\ldots(2)
\]
Example 1: Solve \( z = px + qy + pq \)

Sol. The given equation is of the form \( z = px + qy + f(p, q) \)

let \( p = a \) and \( q = b \) substituting in the given equation, so the complete integral is

\[
z = ax + by + ab
\]

where \( a, b \) being arbitrary constant.

Example 2: Solve \( x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} = z - 5 \frac{\partial z}{\partial x} + \frac{\partial z}{\partial x} \cdot \frac{\partial z}{\partial y} \)

Sol. Rearrange the given equation, we have

\[
x \ p + y \ q = z - 5p + pq
\]

\[
z = x \ p + y \ q + 5p - pq
\]

Equation (3) is of Clariaut form

let \( p = a \) and \( q = b \) substituting in (3), then the complete integral is

\[
z = ax + by + 5a - ab
\]

where \( a, b \) being arbitrary constant.

Example 3: Solve \( px + qy = z - p^3 - q^3 \)

Sol. Rearrange the given equation, we have

\[
z = px + qy + p^3 + q^3
\]

let \( p = a \) and \( q = b \) substituting in (4)

\[
z = ax + by + a^3 + b^3
\] that is the complete integral and
a, b being arbitrary constants.

(1.3.4) The Equation of the form \( f(z, p, q) = 0 \)

To solve the equation of the form

\[ f(z, p, q) = 0 \quad \text{...(1)} \]

1. Let \( u = x + ay \) \quad \text{...(2)}

where \( a \) is an arbitrary constant.

2. Replace \( p \) and \( q \) by \( \frac{dz}{du} \) and \( a \frac{dz}{du} \) respectively in (1) as follows,

\[
    p = \frac{\partial z}{\partial x} = \frac{\partial z}{\partial u} \cdot \frac{\partial u}{\partial x} = \frac{\partial z}{\partial u} \cdot \frac{\partial u}{\partial x} = \frac{dz}{du} \\
    q = \frac{\partial z}{\partial y} = \frac{\partial z}{\partial u} \cdot \frac{\partial u}{\partial y} = \frac{\partial z}{\partial u} \cdot \frac{\partial u}{\partial y} = a \frac{dz}{du} \quad \text{...(3)}
\]

from (2) \( \frac{\partial u}{\partial x} = 1 \) and \( \frac{\partial u}{\partial y} = a \)

3. Substituting (3) in (1) and solve the resulting ordinary differential equation of first order by usual methods.

4. Next, replace \( u \) by \( x + ay \) in the solution obtained in step 3 to get the complete solution.

Example 1: Solve \( z = p + q \)

Sol. Given equation is \( z = p + q \) \quad \text{...(4)}

which is of the form \( f(z, p, q) = 0 \). Let \( u = x + ay \) where \( a \) is an arbitrary constant.

Now, replacing \( p \) and \( q \) by \( \frac{dz}{du} \) and \( a \frac{dz}{du} \) respectively in (4), we get
Chapter One: Methods of solving partial differential equations

\[ z = \frac{dz}{du} + a \frac{dz}{du} \]

\[ \Rightarrow z = (1 + a) \frac{dz}{du} \]

\[ \Rightarrow du = (1 + a) \frac{dz}{z} \] \hspace{1cm} \ldots (5)

Integrating (5), \quad u + c = (1 + a) \ln z

where c is an arbitrary constant

Replacing u,

\[ x + ay + c = \ln z^{(1+a)} \]

\[ \Rightarrow e^{x+ay+c} = z^{(1+a)} \]

\[ \Rightarrow z = e^{\frac{x+ay+c}{1+a}} \] \hspace{1cm} \ldots (6)

and that is the complete integral.

**Example 2:** Solve \( \left( \frac{\partial z}{\partial x} \right)^2 z - \left( \frac{\partial z}{\partial y} \right)^2 = 1 \)

**Sol.** Rearrange the given equation, we have

\[ p^2 z - q^2 = 1 \] \ldots (7)

This equation is of the form \( f(z, p, q) = 0 \)

Let \( u = x + ay \), where a is an arbitrary constant

Now, replacing \( p \) and \( q \) by \( \frac{dz}{du} \) and \( a \frac{dz}{du} \) respectively in (7), we get

\[ \left( \frac{dz}{du} \right)^2 z - \left( a \frac{dz}{du} \right)^2 = 1 \]

\[ \Rightarrow (z - a^2) \left( \frac{dz}{du} \right)^2 = 1 \]
Chapter One: Methods of solving partial differential equations

\[ \pm \sqrt{z - a^2} \frac{dz}{du} = 1 \] by taking the square root

\[ \pm \sqrt{z - a^2} \ dz = du \quad (8) \]

Integrating (8),

\[ \pm \frac{2}{3} (z - a^2)^{3/2} = u + c \quad (9) \]

Replacing \( u \) in (9) to get the complete integral

\[ \pm \frac{2}{3} (z - a^2)^{3/2} = x + ay + c \]

(1.3.5) **The Equation of the form** \( f_1(x, p) = f_2(y, q) = 0 \)

In this form \( z \) does not appear and the terms containing \( x \) and \( p \) are on one side and those containing \( y \) and \( q \) on the other side.

To solve this equation putting

\[ f_1(x, p) = f_2(y, q) = a \quad (1) \]

where \( a \) is an arbitrary constant

\[ \therefore f_1(x, p) = a \quad \Rightarrow \quad p = g_1(x, a) \quad (2) \]

\[ f_2(y, q) = a \quad \Rightarrow \quad q = g_2(y, a) \quad (3) \]

Substituting (2) and (3) in \( dz = p\ dx + q\ dy \), we get

\[ dz = g_1(x, a)\ dx + g_2(y, a)\ dy \quad (4) \]

Integrating (4),

\[ z = \int g_1(x, a)\ dx + \int g_2(y, a)\ dy + b \]

which is a complete integral containing two arbitrary constants \( a \) and \( b \).

**Example 1:** Solve \( p = 2xq^2 \)
Chapter One: Methods of solving partial differential equations

Sol. Separating $p$ and $x$ from $q$ and $y$, the given equation reduces to $\frac{p}{x} = 2q^2$ ...(5)

Equating each side to an arbitrary constant $a$, we have

$$\frac{p}{x} = a \quad \Rightarrow p = ax$$

$$2q^2 = a \quad \Rightarrow q = \pm \sqrt{\frac{a}{2}}$$

Putting these values of $p$ and $q$ in

dz = pdx + qdy , we get

$$dz = axdx \pm \sqrt{\frac{a}{2}} dy$$

Integrating (6), $z = \frac{a}{2} x^2 \pm \sqrt{\frac{a}{2}} y + b$

where $a$ and $b$ are two arbitrary constants.

Example 2: Solve $xq - y^2p - x^2y^2 = 0$

Sol. Separating $p$ and $x$ from $q$ and $y$, the given equation reduces to $\frac{p + x^2}{x} = \frac{q}{y^2}$ ...(7)

Equating each side to an arbitrary constant $a$, we have

$$\frac{p + x^2}{x} = a \quad \Rightarrow p = ax - x^2$$

$$\frac{q}{y^2} = a \quad \Rightarrow q = ay^2$$

Putting (8) and (9) in $dz = pdx + qdy$ , we get

$$dz = (ax - x^2)dx + ay^2 dy$$

Integrating (10), $z = \frac{ax^2}{2} - \frac{x^3}{3} + ay^3 + b$
Chapter One: Methods of solving partial differential equations

which is a complete integral containing two arbitrary constants $a$ and $b$.

**Example 3: Solve $p - 3x^2 = q^2 - y$**

**Sol.** Equating each side to an arbitrary constant $a$, we get

\[
p - 3x^2 = a \quad \Rightarrow \quad p = a + 3x^2 \quad \ldots(11)
\]

\[
q^2 - y = a \quad \Rightarrow \quad q = \pm \sqrt{a + y} \quad \ldots(12)
\]

Putting these values of $p$ and $q$ in $\,dz = pdx + qdy\,$, we get

\[
\sqrt{\ldots(11)}
\]

\[
\sqrt{\ldots(12)}
\]

Integrating (13),

\[
\frac{\partial f}{\partial x} + p \frac{\partial f}{\partial z} = \frac{\partial f}{\partial y} + q \frac{\partial f}{\partial z} = -p \frac{\partial f}{\partial p} - q \frac{\partial f}{\partial q} = - \frac{\partial f}{\partial p} = - \frac{\partial f}{\partial q}
\]

which is a complete integral containing two arbitrary constant $a$ and $b$.

**(1.3.6) Charpit’s Method (General Method of Solving p.d.es of Order One but of any Degree)**

Let the given p.d.e of first order and non-linear in $p$ and $q$ be

\[
f(x,y,z,p,q) = 0 \quad \ldots(1)
\]

To solve this equation we will use the following charpit’s auxiliary equations.

\[
\frac{dp}{f_x + pf_z} = \frac{dq}{f_y + qf_z} = \frac{dz}{-pf_p - qf_q} = \frac{dx}{-f_p} = \frac{dy}{-f_q}
\]

or

\[
\frac{dp}{f_x + pf_z} = \frac{dq}{f_y + qf_z} = \frac{dz}{-pf_p - qf_q} = \frac{dx}{-f_p} = \frac{dy}{-f_q}
\]
Chapter One: Methods of solving partial differential equations

After substituting the partial derivatives in charpit’s auxiliary equations select the proper fractions so that the resulting integral may come out to be the simplest relation involving at least one of $p$ and $q$.

Then, putting $p$ and $q$ in the relation $dz = pdx + qdy$ which on integration gives the complete integral of the given equation.

**Example 1: Solve** $z = px + qy + p^2 + q^2$ **by charpit’s method.**

**Sol.** Let $f(x, y, z, p, q) = z - px - qy - p^2 - q^2 = 0 \ldots (2)$

charpit’s auxiliary equation are

\[
\begin{align*}
\frac{dp}{f_x + pf_z} &= \frac{dq}{f_y + qf_z} = \frac{dz}{-pf_p - qf_q} = \frac{dx}{-f_p} = \frac{dy}{-f_q}
\end{align*}
\]

From (2) $f_x = -p, f_y = -q, f_z = 1, f_p = -x - 2p, f_q = -y - 2q$

\[
\begin{align*}
\therefore \frac{dp}{-p + p} &= \frac{dq}{-q + q} = \frac{dz}{p(x + 2p) + q(y + 2q)} = \frac{dx}{x + 2p} \\
&= \frac{dy}{y + 2q}
\end{align*}
\]

Taking the first fraction $dp = 0 \rightarrow p = a \ldots (3)$

Taking the second fraction $dq = 0 \rightarrow q = b \ldots (4)$

Substituting (3) and (4) in (2) to get the complete integral

\[z = ax + by + a^2 + b^2\]

where $a$ and $b$ are arbitrary constants.

**Example 2: Solve** $2zx - px^2 - 2qxy + pq = 0$ **by charpit’s method.**

**Sol.** Let $f(x, y, z, p, q) = 2zx - px^2 - 2qxy + pq = 0 \ldots (5)$
Chapter One: Methods of solving partial differential equations

\( f_x = 2z - 2px - 2qy, \quad f_y = -2qx, \quad f_z = 2xf_p = -x^2 + q, \quad f_q = -2xy + p \)

Substituting in charpit’s auxiliary equations, we get

\[
\frac{dp}{2z-2px-2qy+2px} = \frac{dq}{-2qz+2qx} = \frac{dz}{-p(-x^2+q)-q(-2xy+p)} = \frac{dx}{x^2-q} = \frac{dy}{2xy-p} \quad \ldots(6)
\]

Taking the second fraction of (6)

\( dq = 0 \quad \rightarrow \quad q = c \ldots(7) \)

Substituting (7) in (5)

\[ 2zx - px^2 - 2cxy + cp = 0 \]

\[ p = \frac{2xz-2cxy}{x^2-c} \quad \rightarrow \quad p = \frac{2x(z-cy)}{x^2-c} \ldots(8) \]

Putting (7) and (8) in \( dz = pdx + qdy \)

\[
\frac{dz}{dx} = \frac{2x(z-cy)}{x^2-c} \quad \Rightarrow \quad dz - cdy = \frac{2x(z-cy)}{x^2-c} \quad dx
\]

\[
\frac{dz-cdy}{(z-cy)} = \frac{2x \, dx}{x^2-c} \ldots(9)
\]

Integrating (9), \( ln|z-cy| = ln|x^2-c| + ln b \)

\[ z-cy = b(x^2-c) \]

\[ z = b(x^2-c) + cy \]

which is a complete integral where \( b \) and \( c \) are two arbitrary constants.

... Exercises ...

Solve the following equations:

1. \( q = 3p^2 \)
2. \( zpq = p + q \)
3. \( p^2 - y^2q = y^2 - x^2 \)
4. \( (y^2 + 4)xpq - (x^2 + 2) = 0 \)
5. \( q - px - p^2 = 0 \)
6. \( px + qy = pq \)
7. \( \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y} = \frac{y}{x} \)
8. \( p^2 - q^2 = z \)

(1.3.7) **Using Some Hypotheses in the Solution**

Sometimes we need some hypotheses to solve the partial differential equation, here we will give three types of hypotheses.

**A)** When the equation contains the term \((px)\) or its’ powers we use the hypothesis \(X = \ln x\)

as follows

\[
p = \frac{\partial z}{\partial x} = \frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial x} = \frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial x} = \frac{\partial z}{\partial x} \cdot \frac{1}{x} \quad \text{(since } X = \ln x \implies \frac{\partial x}{\partial x} = \frac{1}{x})
\]

\[
\Rightarrow xp = \frac{\partial z}{\partial X}
\]

Then substituting this result in the given equation and solve it by previous methods.

**Example 1:** Solve \(z = px\) by hypotheses

**Sol.** From \(X = \ln x\) we have \(xp = \frac{\partial z}{\partial x}\) \(\ldots(1)\)

Substituting (1) in the given equation, we get

\[
z = \frac{\partial z}{\partial x} \quad \Rightarrow \quad \partial X = \frac{\partial z}{z} \quad \ldots(2)
\]

Integrating (2), \(X = \ln z + \ln \phi(y)\) \(\ldots(3)\)

where \(\phi\) is an arbitrary function for \(y\)

replacing \(X\) in (3) to get the complete integral

\[
\ln x = \ln \phi(y) \cdot z
\]
Example 2: Solve \( q = px + p^2 x^2 \) by hypotheses

**Sol.** Given that \( q = px + (px)^2 \) \( \ldots (5) \)

from \( X = \ln x \) we have \( xp = \frac{\partial z}{\partial X} \) \( \ldots (6) \)

Substituting (6) in (5), we get

\[
q = \frac{\partial z}{\partial X} + \left( \frac{\partial z}{\partial X} \right)^2 \tag{7}
\]

Let \( \frac{\partial z}{\partial X} = t \) then (7) will be

\[
q = t + t^2 \tag{8}
\]

The equation (8) is of the form \( f(t, q) = 0 \)

Then let \( t = a \) and \( q = b \), putting in (8) \( b = a + a^2 \)

Substituting in \( z = aX + by + c \)

\[
\Rightarrow z = aX + (a + a^2)y + c \ldots (9)
\]

where \( c \) is an arbitrary constant

replacing \( X \) in (9) to get the complete integral

\[
z = a \ln x + (a + a^2)y + c
\]

**B)** When the equation contains the term \((qy)\) or its’ powers we use the hypothesis \( Y = \ln y \)

as follows:

\[
q = \frac{\partial z}{\partial y} = \frac{\partial z}{\partial Y} \cdot \frac{\partial Y}{\partial y} = \frac{\partial z}{\partial Y} \cdot \frac{\partial Y}{\partial y} = \frac{\partial z}{\partial y} \cdot \frac{1}{y} \quad \text{(since} \quad Y = \ln y \Rightarrow \frac{\partial Y}{\partial y} = \frac{1}{y})
\]
Chapter One: Methods of solving partial differential equations

\[ \Rightarrow qy = \frac{\partial z}{\partial Y} \]

Then solving by the same way in (A).

**Example 3: Solve** \( 2p + qy = 4 \) **by hypotheses**

**Sol.** Given that \( 2p + qy = 4 \) \( \ldots (10) \)

from \( Y = \ln y \) we have \( qy = \frac{\partial z}{\partial Y} \) \( \ldots (11) \)

Substituting (11) in (10), we get

\[ 2p + \frac{\partial z}{\partial Y} = 4 \]

Let \( \frac{\partial z}{\partial Y} = t \) then,

\[ 2p + t = 4 \] \( \ldots (12) \)

The equation (12) is of the form \( f(p, t) = 0 \)

Then let \( p = a \) and \( t = b \), putting in (12) \( 2a + b = 4 \)

\[ \Rightarrow b = 4 - 2a \] \( \ldots (13) \)

Substituting (13) in \( z = ax + bY + c \)

\[ \Rightarrow z = ax + (4 - 2a)Y + c \ldots (14) \]

where \( c \) is an arbitrary constant

replacing \( Y \) in (14) to get the complete integral

\[ z = ax + (4 - 2a) \ln y + c \]

**Example 4: Solve** \( p^2x^2 = z^2 + q^2y^2 \) **by hypotheses**

**Sol.** Given that \( p^2x^2 = z^2 + q^2y^2 \) \( \ldots (15) \)

from \( X = \ln x \) and \( Y = \ln y \) we have
Chapter One: Methods of solving partial differential equations

\[ xp = \frac{\partial z}{\partial x} \text{ and } qy = \frac{\partial z}{\partial y} \]  
\[ \ldots(16) \]

Substituting (16) in (15), we get

\[ \left( \frac{\partial z}{\partial x} \right)^2 = z^2 + \left( \frac{\partial z}{\partial y} \right)^2 \]  
\[ \ldots(17) \]

Let \( t = \frac{\partial z}{\partial x} \) and \( r = \frac{\partial z}{\partial y} \) putting in (17)

\[ t^2 - r^2 = z^2 \]  
\[ \ldots(18) \]

Note that (18) is of the form \( f(t, r, z) = 0 \)

Taking \( u = X + aY \) \((a \text{ is constant})\)

Then \( t = \frac{\partial z}{\partial X} = \frac{\partial z}{\partial X} \cdot \frac{\partial u}{\partial u} = \frac{\partial z}{\partial u} \cdot \frac{\partial u}{\partial X} = \frac{dz}{du} \)

\[ r = \frac{\partial z}{\partial Y} = \frac{\partial z}{\partial Y} \cdot \frac{\partial u}{\partial u} = \frac{\partial z}{\partial u} \cdot \frac{\partial u}{\partial Y} = a \frac{dz}{du} \]  
\[ \ldots(19) \]

because \( \frac{\partial u}{\partial X} = 1 \) and \( \frac{\partial u}{\partial Y} = a \)

putting (19) in (18)

\[ \left( \frac{dz}{du} \right)^2 - a^2 \left( \frac{dz}{du} \right)^2 = z^2 \]

\[ \left( 1 - a^2 \right) \left( \frac{dz}{du} \right)^2 = z^2 \]

\[ \pm \sqrt{1 - a^2} \frac{dz}{du} = z \]  
(taking the square root)

\[ \pm \sqrt{1 - a^2} \frac{dz}{z} = du \]  
\[ \ldots(20) \]

Integrating (20),

\[ \pm \sqrt{1 - a^2} \ln z = u + c \]  
\((c \text{ is constant})\)  
\[ \ldots(21) \]

Now, replacing \( u \) in (21) to get the complete integral

\[ \pm \sqrt{1 - a^2} \ln z = X + aY + \ln c \]  
\[ \ldots(22) \]

Next, replacing \( X \) and \( Y \) in (22) to get the complete integral
\[ \pm \sqrt{1 - a^2} \ln z = \ln x + a \ln y + \ln c \]
\[ \ln z^b = \ln cx^a y^a \quad \text{where} \quad b = \pm \sqrt{1 - a^2} \]
\[ \implies z^b = cx^a y^a \quad \ldots(23) \]
So, (23) is the complete integral.

C) When the equation contains the terms \( \frac{p}{z} \) or \( \frac{q}{z} \) or its’ powers we use the hypothesis \( Z = \ln z \) as follows:
\[ p = \frac{\partial z}{\partial x} = \frac{\partial z}{\partial x} \cdot \frac{\partial z}{\partial z} = \frac{\partial z}{\partial z} \cdot \frac{\partial z}{\partial x} = z \frac{\partial z}{\partial x} \quad \text{(since} \quad \frac{\partial z}{\partial z} = z) \]

hence \( \frac{p}{z} = \frac{\partial z}{\partial x} \)

by the same way we have \( \frac{q}{z} = \frac{\partial z}{\partial y} \)

then substituting this terms in the given equation and solve it by the same way in (A) and (B).

**Example 5: Solve** \( px + qy = z \) by \( Z = \ln z \)

**Sol.** Given that \( px + qy = z \) \( \ldots(24) \)

Dividing on \( z \), \( \frac{p}{z}x + \frac{q}{z}y = 1 \) \( \ldots(25) \)

using \( Z = \ln z \) we have \( \frac{p}{z} = \frac{\partial z}{\partial x} \) and \( \frac{q}{z} = \frac{\partial z}{\partial y} \), substituting in (25)

\[ x \frac{\partial z}{\partial x} + y \frac{\partial z}{\partial y} = 1 \quad \ldots(26) \]

Let \( t = \frac{\partial z}{\partial x} \) and \( r = \frac{\partial z}{\partial y} \) thus, (26) would be

\[ xt + yr = 1 \quad \ldots(27) \]

Clear that (27) is of the form \( f_1(x, t) = f_2(y, r) \)

Then putting \( x, p \) in one side and \( y, q \) in the other side
Chapter One: Methods of solving partial differential equations

\[ xt = 1 - ry = a \quad (a \text{ is constant}) \]

Then \[ xt = a \rightarrow t = \frac{a}{x} \quad \ldots(28) \]

\[ 1 - ry = a \rightarrow r = \frac{1-a}{y} \quad \ldots(29) \]

Substituting (28), (29) in \[ dZ = tdx + rdy \]

\[ \Rightarrow dZ = \frac{a}{x} dx + \frac{1-a}{y} dy \quad \ldots(30) \]

Integrating (30), we get \[ Z = a \ln x + (1 - a) \ln y + \ln b \quad (\text{where } b \text{ is constant}) \]

Replacing \( Z \) from the hypothesis to get the complete integral \[ \therefore \ln z = \ln(bx^a y^{(1-a)}) \quad (\text{by properties of } \ln) \]

\[ \Rightarrow \left[ \frac{z}{b} x^a y^{(1-a)} \right] \quad \ldots(31) \]

Then (31) is the complete integral.

**Example 6**: Solve \( p^2 + q^2 = z^2(x + y) \) by hypotheses

**Sol.** Dividing on \( z^2 \), \[ \frac{p^2}{z^2} + \frac{q^2}{z^2} = x + y \quad \ldots(32) \]

using \( Z = \ln z \) we have \( \frac{p}{z} = \frac{\partial Z}{\partial x} \) and \( \frac{q}{z} = \frac{\partial Z}{\partial y} \), substituting in (32)

\[ \left(\frac{\partial Z}{\partial x}\right)^2 + \left(\frac{\partial Z}{\partial y}\right)^2 = x + y \quad \ldots(33) \]

Let \( t = \frac{\partial Z}{\partial x} \) and \( r = \frac{\partial Z}{\partial y} \) putting in (33)

\[ t^2 + r^2 = x + y \quad \ldots(34) \]

Then \( t^2 - x = a \rightarrow t = \pm \sqrt{a + x} \]

\[ y - r^2 = a \rightarrow r = \pm \sqrt{y - a} \]

Substituting in \( dZ = tdx + rdy \)
\[ dZ = \pm \sqrt{a + x} \, dx + \pm \sqrt{y - ad} \, dy \quad \quad \text{(35)} \]

Integrating (35), we get

\[ Z = \pm \frac{2}{3} (a + x)^{3/2} \pm \frac{2}{3} (y - a)^{3/2} + c \quad \text{(where c is constant)} \]

Replacing \( Z \) from the hypothesis to get the complete integral

\[ \Rightarrow \ln z = \pm \frac{2}{3} (a + x)^{3/2} \pm \frac{2}{3} (y - a)^{3/2} + c \]

... Exercises ...

1. \( p^2 x^2 = z(z - qy) \)
2. \( pq = z^2 y \sec x \)
3. \( p + q = z e^{x+y} \)
4. \( p^2 + zq = z^2 (x - y) \)
5. \( p^2 + zp = z^2 (x - y) \)
6. \( p^2 + q^2 = z^2 \)
7. \( xp + 4q = \cos y \)
8. \( p^2 + q^2 = z^2 y \)
Section(1.4): Homogeneous linear partial differential equations with constant coefficients and higher order

A linear partial differential equation with constant coefficients is called homogeneous if all its derivatives are of the same order. The general form of such an equation is

\[ A_0 \frac{\partial^n z}{\partial x^n} + A_1 \frac{\partial^n z}{\partial x^{n-1} \partial y} + \cdots + A_n \frac{\partial^n z}{\partial y^n} = f(x, y) \quad \text{...............}(1) \]

Where \( A_0, A_1, \ldots, A_n \) are constant coefficients.

For example:

1. \( 3 \frac{\partial^2 z}{\partial x^2} + 5 \frac{\partial^2 z}{\partial x \partial y} + \frac{\partial^2 y}{\partial y^2} = 0 \) hom. of order 2.

2. \( 2 \frac{\partial^3 z}{\partial x^3} - 3 \frac{\partial^3 z}{\partial x^2 \partial y} + 5 \frac{\partial^3 z}{\partial x \partial y^2} - 8 \frac{\partial^3 y}{\partial y^3} = x + y \) hom. of order 3.

For convenience \( \frac{\partial}{\partial x} \) and \( \frac{\partial}{\partial y} \) will be denoted by \( D \) or \( D_x \) and \( D' \) or \( D_y \) respectively. Then (1) can be rewritten as:

\[ (A_0 D_x^n + A_1 D_x^{n-1} D_y + \cdots + A_n D_y^n)z = f(x, y) \quad \text{...............}(2) \]

On the other hand, when all the derivatives in the given equation are not of the same order, then it is called a non-homogenous linear partial differential equation with constant coefficients.
Chapter One: Methods of solving partial differential equations

In this section we propose to study the various methods of solving homogeneous linear partial differential equation with constant coefficients, namely (2).

Equation (2) may rewritten as:

\[ F(D_x, D_y)z = f(x, y) \]  

\[ \text{..............(3)} \]

Where \[ F(D_x, D_y) = A_0 D_x^n + A_1 D_x^{n-1} D_y + \ldots + A_n D_y^n \]

Equation (3) has a general solution when \( f(x, y) = 0 \)

i.e \( F(D_x, D_y)z = 0 \)

\[ \rightarrow (A_0 D_x^n + A_1 D_x^{n-1} D_y + \ldots + A_n D_y^n)z = 0, \text{.........(4)} \]

And a particular solution (particular integral) when \( f(x, y) \neq 0 \)

\[ \text{Now, we will find the general solution of (4)} \]

Let \( z = \phi(y + mx) \) be a solution of (4) where \( \phi \) is an arbitrary function and \( m \) is a constant, then

\[ D_x z = \phi'(y + mx).m \]

\[ D_x^2 z = \phi''(y + mx).m^2 \]

\[ \vdots \]

\[ D_x^n z = \phi^{(n)}(y + mx).m^n \]

\[ \text{------------------------------------------} \]

\[ D_y z = \phi'(y + mx) \]

\[ D_y^2 z = \phi''(y + mx) \]

\[ \vdots \]

\[ D_y^n z = \phi^{(n)}(y + mx) \]

\[ \text{------------------------------------------} \]
Chapter One: Methods of solving partial differential equations

\[ D_x D_y z = m \phi'(y + mx) \]
\[ D_x^2 D_y z = m^2 \phi^{(3)}(y + mx) \]
\[ \vdots \]
\[ D_x^r D_y^s z = m^r \phi^{(r+s)}(y + mx) = m^r \phi^{(n)}(y + mx), \quad \text{where} \quad r + s = n \]

Substituting these values in (4) and simplifying, we get:

\[(A_0 m^n + A_1 m^{n-1} + A_2 m^{n-2} + \cdots + A_n) \phi^{(n)}(y + mx) = 0 \quad \ldots \ldots (5)\]

Which is true if \( m \) is a root of the equation

\[ A_0 m^n + A_1 m^{n-1} + A_2 m^{n-2} + \cdots + A_n = 0 \quad \ldots \ldots (6) \]

The equation (6) is known as the (characteristic equation) or the \( \text{(auxiliary equation(A.E.))} \) and is obtained by putting \( D_x = m \) and \( D_y = 1 \) in \( F(D_x, D_y)z = 0 \), and it has \( n \) roots.

Let \( m_1, m_2, \ldots, m_n \) be \( n \) roots of A.E. (6). **Three cases arise:**

**Case 1** when the roots are distinct.

If \( m_1, m_2, \ldots, m_n \) are \( n \) distinct roots of A.E. (6) then \( \phi_1(y + m_1x), \phi_2(y + m_2x), \ldots \ldots, \phi_n(y + m_nx) \) are the linear solutions corresponding to them and since the sum of any linear solutions is a solution too then the general solution in this case is:

\[ z = \phi_1(y + m_1x) + \phi_2(y + m_2x) + \cdots + \phi_n(y + m_nx) \quad \ldots \ldots (7) \]

**Ex.1:** Find the general solution of

\[ (D_x^3 D_y + 2D_x^2 D_y - 5D_x D_y^2 - 6D_y^3)z = 0 \]

Sol. The A.E. is \( m^3 + 2m^2 - 5m - 6 = 0 \)

\[ \rightarrow (m + 1)(m^2 + m - 6) = 0 \]
Chapter One: Methods of solving partial differential equations

\[ \rightarrow (m + 1)(m + 3)(m - 2) = 0 \]

\[ m_1 = -1, \ m_2 = -3, \ m_3 = 2 \]

Note that \( m_1, m_2 \) and \( m_3 \) are different roots, then the general solution is

\[ z = \varphi_1(y + m_1 x) + \varphi_2(y + m_2 x) + \varphi_3(y + m_3 x) \]

\[ \rightarrow z = \varphi_1(y - x) + \varphi_2(y - 3x) + \varphi_3(y + 2x) \]

Where \( \varphi_1, \varphi_2, \varphi_3 \) are arbitrary functions.

**Ex.2:** Find the general solution of \( m^2 - a^2 = 0 \) where \( a \) is a real number.

Sol. Given that \( m^2 - a^2 = 0 \rightarrow m^2 = a^2 \)

\[ \rightarrow m = \pm a \quad \text{different root} \]

\[ m_1 = a, m_2 = -a \]

The general solution is

\[ z = \varphi_1(y + ax) + \varphi_2(y - ax) \]

Where \( \varphi_1, \varphi_2 \) are arbitrary functions.

**Case 2 when the roots are repeated.**

If the root \( m \) is repeated \( k \) times \( \text{i.e.} m_1 = m_2 = \cdots = m_k \), then the corresponding solution is :

\[ z = \varphi_1(y + m_1 x) + x\varphi_2(y + m_1 x) + \cdots + x^{k-1}\varphi_{n}(y + m_1 x) \cdots (8) \]

Where \( \varphi_1, ..., \varphi_k \) are arbitrary functions.

**Note:** If some of the roots \( m_1, m_2, ..., m_n \) are repeated and the other are not \( \text{i.e.} m_1 = m_2 = \cdots = m_k \neq m_{k+1} \neq \cdots \neq m_n \) then the general solution is :
Chapter One: Methods of solving partial differential equations

\[ z = \phi_1(y + m_1x) + x\phi_2(y + m_1x) + \cdots + x^{k-1}\phi_n(y + m_1x) + \phi_{k+1}(y + m_{k+1}x) + \cdots + \phi_n(y + m_nx) \] \hspace{1cm} \ldots \ldots \ldots \ldots (9)

**Ex.3:** Solve \((D_x^3 - D_x^2D_y - 8D_xD_y^2 + 12D_y^3)z = 0\)

Sol. The A.E. is \(m^3 - m^2 - 8m + 12 = 0\)

\[ \rightarrow (m - 2)(m - 2)(m + 3) = 0 \]

\(m_1 = m_2 = 2, \quad m_3 = -3\)

Then, the general solution is

\[ z = \phi_1(y + 2x) + x\phi_2(y + 2x) + \phi_3(y - 3x) \]

Where \(\phi_1, \phi_2, \phi_3\) are arbitrary functions.

**Ex.4:** Find the general solution of the equation that its A.E. is:

\[ (m - 1)^2(m + 2)^3(m - 3)(m + 4) = 0 \]

Sol. Given that \((m - 1)^2(m + 2)^3(m - 3)(m + 4) = 0\)

\(m_1 = m_2 = 1, \quad m_3 = m_4 = m_5 = -2, \quad m_6 = 3, \quad m_7 = -4\)

The general solution is

\[ z = \phi_1(y + x) + x\phi_2(y + x) + \phi_3(y - 2x) + x\phi_4(y - 2x) + x^2\phi_5(y - 2x) + \phi_6(y + 3x) + \phi_7(y - 4x) \]

Where \(\phi_1, \ldots, \phi_7\) are arbitrary functions.

**Case 3** when the roots are complex.
If one of the roots of the given equation is complex let be $m_1$ then the conjugate of $m_1$ is also a root, let be $m_2$, so the general solution is:

$$z = \phi_1(y + m_1x) + \phi_2(y + m_2x) + \cdots + \phi_n(y + m_nx)$$

Where $\phi_1, \ldots, \phi_n$ are arbitrary functions.

**Ex.5**: Solve $(D_x^2 + D_y^2)z = 0$

Sol. The A.E. is $m^2 + 1 = 0 \rightarrow m = \pm i$

$$\therefore \ m_1 = i \quad , \ m_2 = -i$$

The general solution is

$$z = \phi_1(y + ix) + \phi_2(y - ix)$$

Where $\phi_1, \phi_2$ are arbitrary functions.

**Ex.6**: Solve $(D_x^2 - 2D_xD_y + 5D_y^2)z = 0$

Sol. The A.E. is $m^2 - 2m + 5 = 0$

$$\rightarrow \ m = \frac{2 \pm \sqrt{4 - 20}}{2} = 1 \pm 2i$$

$$\therefore \ m_1 = 1 + 2i \quad , \ m_2 = 1 - 2i$$

$$z = \phi_1(y + (1 + 2i)x) + \phi_2(y + (1 - 2i)x)$$

That is the general solution where $\phi_1, \phi_2$ are arbitrary functions.

**Ex.7**: Solve $(D_x^4 - D_x^3D_y + 2D_x^2D_y^2 - 5D_xD_y^3 + 3D_y^4)z = 0$

Sol. The A.E. is $m^4 - m^3 + 2m^2 - 5m + 3 = 0$

$$\rightarrow \ (m - 1)^2(m^2 + m + 3) = 0$$
Then, the general solution is
\[ z = \phi_1(y + x) + x\phi_2(y + x) + \phi_3\left(y + \left(\frac{-1 + \sqrt{11}i}{2}\right)x\right) \]
\[ + \phi_4\left(y + \left(\frac{-1 - \sqrt{11}i}{2}\right)x\right) \]

Where \( \phi_1, ..., \phi_4 \) are arbitrary functions.

**Particular integral (P.I.) of homogeneous linear partial differential equation**

When \( f(x, y) \neq 0 \) in the equation (3) which it's \( F(D_x, D_y)z = f(x, y) \) multiplying (3) by the inverse operator \( \frac{1}{F(D_x, D_y)} \) of the operator \( F(D_x, D_y) \) to have
\[ \frac{1}{F(D_x, D_y)} \cdot F(D_x, D_y) z = \frac{1}{F(D_x, D_y)} f(x, y) \]
\[ \rightarrow z = \frac{1}{F(D_x, D_y)} f(x, y) \] \[ \ldots \ldots \text{(11)} \]

Which it's the particular integral (P.I.)

The operator \( F(D_x, D_y) \) can be written as
\[ F(D_x, D_y) = (D_x - m_1D_y)(D_x - m_2D_y) \ldots (D_x - m_nD_y) \] \[ \ldots \ldots \text{(12)} \]
Substituting (12) in (11) :
Chapter One: Methods of solving partial differential equations

\[ z = \frac{1}{(D_x - m_1D_y)(D_x - m_2D_y)\ldots(D_x - m_mD_y)} \ f(x, y) \quad \ldots \ldots \ldots (13) \]

Taking \[ u_1 = \frac{1}{D_x - m_mD_y} \] \( f(x, y) \)

\[ \therefore \ (D_x - m_mD_y)u_1 = f(x, y) \]

This equation can be solved by Lagrange's method.

The Lagrange's auxiliary equations are

\[ \frac{dx}{1} = \frac{dy}{-m_n} = \frac{du_1}{f(x,y)} \quad \ldots \ldots (14) \]

Taking the first two fractions of (14)

\[ m_n \ dx + \ dy = 0 \quad \rightarrow \quad m_n x + y = a \quad \ldots \ldots (15) \]

Taking the first and third fractions of (14)

\[ dx = \frac{du_1}{f(x,y)} \quad \rightarrow \quad f(x,y)dx = du_1 \quad \ldots \ldots (16) \]

Substituting (15) in (16) we have

\[ f(x, a - m_nx)dx = du_1 \]

Integrating the last one we have

\[ u_1 = \int f(x, a - m_nx)dx + b \]

Let \( b = 0 \), then we have \( u_1 \)

By the same way, we take

\[ u_2 = \frac{1}{D_x - m_{n-1}D_y}u_1 \]

And solve it by Lagrange's method to get \( u_2 \), then continue in this way until we get to

\[ z = u_n = \frac{1}{D_x - m_1D_y}u_{n-1} \]
And by solving this equation we get the particular integral (P.I.)

**Ex.1: solve** \((D_x^2 - D_y^2)z = \sec^2(x + y)\)

**Sol.** Firstly, we will find the general solution of

\[(D_x^2 - D_y^2)z = 0 \quad ...........(1)\]

The A. E. is \(m^2 - 1 = 0 \rightarrow m^2 = 1 \rightarrow m = \pm 1\)

\[\therefore m_1 = 1, \; m_2 = -1\]

\[\therefore z = \phi_1(y + x) + \phi_2(y - x) \quad ...........(2)\]

Where \(\phi_1, \phi_2\) are arbitrary functions.

Second, we will find the particular integral as follows

\[z_2 = \frac{1}{D_x^2 - D_y^2} \sec^2(x + y)\]

\[= \frac{1}{(D_x - D_y)(D_x + D_y)} \sec^2(x + y)\]

Let \(u_1 = \frac{1}{(D_x + D_y)} \sec^2(x + y)\)

\[(D_x + D_y)u_1 = \sec^2(x + y)\]

The Lagrange's auxiliary equations are

\[\frac{dx}{1} = \frac{dy}{1} = \frac{du_1}{\sec^2(x + y)}\]

Taking the first two fractions

\(dx = dy \quad \rightarrow \quad x - y = a \quad ...........(3)\)

Taking the first and third fractions

\[dx = \frac{du_1}{\sec^2(x + y)} \quad \rightarrow \quad \sec^2(x + y) \; dx = du_1 \quad ...........(4)\]

Substituting (3) in (4), we have
sec²(2x – a) \, dx = du₁ \quad \ldots \ldots \ldots \ldots (5)

Integrating (5), we have

\[ u₁ = \frac{1}{2} \tan(2x - a) + b \]

Let \( b = 0 \) and replacing \( a \), we get

\[ u₁ = \frac{1}{2} \tan(x + y) \quad \ldots \ldots \ldots \ldots (6) \]

Putting (6) in \( z₂ \)

\[ z₂ = \frac{1}{(D_x - D_y)} \cdot \frac{1}{2} \tan(x + y) \]

\[ \rightarrow (D_x - D_y)z₂ = \frac{1}{2} \tan(x + y) \]

The Lagrange's auxiliary equation are

\[ \frac{dx}{1} = \frac{dy}{-1} = \frac{dz₂}{\frac{1}{2} \tan(x + y)} \]

Taking the first two fractions

\[ dx = -dy \quad \rightarrow \quad x + y = a \quad \ldots \ldots \ldots \ldots (7) \]

Taking the first and third fractions

\[ dx = \frac{dz₂}{\frac{1}{2} \tan(x + y)} \]

\[ \frac{1}{2} \tan(x + y) \, dx = dz₂ \quad \ldots \ldots \ldots \ldots (8) \]

Substituting (7) in (8)

\[ \frac{1}{2} \tan a \, dx = dz₂ \quad \ldots \ldots \ldots \ldots (9) \]

Integrating (9), we get

\[ \frac{1}{2} x \tan a = z₂ + b \]
Let \( b = 0 \), and replacing \( a \) from (7) we get the particular integral
\[
z_2 = \frac{1}{2} x \tan(x + y) \quad (10)
\]
Hence the required general solution is
\[
z = z_1 + z_2 = \phi_1(y + x) + \phi_2(y - x) + \frac{x}{2} \tan(x + y) \quad (11)
\]

Short methods of finding the P.I. in certain cases:

**Case 1** When \( f(x, y) = e^{ax+by} \) where \( a \) and \( b \) are arbitrary constants

To find the P.I. when \( F(a, b) \neq 0 \), we derive \( f(x, y) \) for \( x \) any \( y \) \( n \) times:

\[
D_x e^{ax+by} = ae^{ax+by}
\]
\[
D_x^2 e^{ax+by} = a^2 e^{ax+by}
\]
\[
\vdots
\]
\[
D_x^n e^{ax+by} = a^n e^{ax+by}
\]

\[
D_y e^{ax+by} = be^{ax+by}
\]
\[
D_y^2 e^{ax+by} = b^2 e^{ax+by}
\]
\[
\vdots
\]
\[
D_y^n e^{ax+by} = b^n e^{ax+by}
\]

\[
D_x^r D_y^s e^{ax+by} = a^r b^s e^{ax+by} \quad \text{where} \quad r + s = n
\]

So
\[
F(D_x, D_y) e^{ax+by} = F(a, b) e^{ax+by}
\]
Chapter One: Methods of solving partial differential equations

Multiplying both sides by \( \frac{1}{F(D_x, D_y)} \), we get

\[ e^{ax+by} = \frac{1}{F(D_x, D_y)} F(a, b) e^{ax+by} \]

Since \( F(a, b) \neq 0 \), then we can divide on it:

\[ \frac{1}{F(a, b)} e^{ax+by} = \frac{1}{F(D_x, D_y)} e^{ax+by} \quad \text{..................*} \]

Which it is equal to \( z \), then the P.I. is

\[ z = \frac{1}{F(D_x, D_y)} e^{ax+by} = \frac{1}{F(a, b)} e^{ax+by} \]

, where \( F(a, b) \neq 0 \)

when \( F(a, b) = 0 \), then analyze \( F(D_x, D_y) \) as follows

\[ F(D_x, D_y) = (D_x - \frac{a}{b} D_y)^r G(D_x, D_y) \]

Where \( G(a, b) \neq 0 \), we get

\[ z = \frac{1}{F(D_x, D_y)} e^{ax+by} = \frac{1}{(D_x - \frac{a}{b} D_y)^r G(D_x, D_y)} e^{ax+by} \]

\[ = \frac{1}{(D_x - \frac{a}{b} D_y)^r} \cdot \frac{1}{G(a, b)} e^{ax+by} \text{ from *} \]

Since \( G(a, b) \neq 0 \)

\[ = \frac{1}{G(a, b)} \cdot \frac{1}{(D_x - \frac{a}{b} D_y)^r} e^{ax+by} \]

Then by Lagrange's method \( r \) times, we get

\[ z = \frac{1}{F(D_x, D_y)} e^{ax+by} = \frac{1}{G(a, b)} \cdot \frac{x^r}{r!} e^{ax+by} \]

Which it's the P.I. where \( F(a, b) = 0 \), \( G(a, b) \neq 0 \)
Ex.2: Solve \((D_x^2 - D_x D_y - 6D_y^2)z = e^{2x-3y}\)

Sol.

1) To find the general solution

The A.E. of the given equation is

\[ m^2 - m - 6 = 0 \rightarrow (m - 3)(m + 2) = 0 \]

\[ \therefore m_1 = 3 , \quad m_2 = -2 \]

\[ \therefore z_1 = \phi_1(y + 3x) + \phi_2(y - 2x) \]

Where \(\phi_1\) and \(\phi_2\) are arbitrary functions

2) To find the particular Integral (P.I.)

\[ a = 2 \quad , b = -3 \]

\[ F(a, b) = a^2 - ab - 6b^2 \]

\[ F(2, -3) = 4 + 6 - 54 = -44 \neq 0 \]

\[ z_2 = \frac{1}{F(a, b)} e^{ax+by} = \frac{1}{-44} e^{2x-3y} \]

\[ \therefore z = z_1 + z_2 \]

\[ = \phi_1(y + 3x) + \phi_2(y - 2x) - \frac{1}{44} e^{2x-3y} \]

Ex.3: Solve \((D_x^2 - D_x D_y - 6D_y^2)z = e^{3x+y}\)

Sol.

1) The general solution is similar to that in Ex.2

2) To find P.I.

\[ a = 3 \quad , b = 1 \]

\[ F(a, b) = a^2 - ab - 6b^2 \]
Chapter One: Methods of solving partial differential equations

\[ F(3,1) = 9 - 3 - 6 = 0 , \]

analyze \( F(D_x, D_y).F(D_x, D_y) = D_x^2 - D_x D_y - 6D_y^2 \)
\[ = (D_x - 3D_y)(D_x + 2D_y) \]

\( (D_x - \frac{a}{b}D_y)^r \rightarrow r = 1, \ 3 + 2 = 5 \neq 0 = G \)

\[ z_2 = \frac{1}{G(a,b)} \cdot \frac{x^r}{r!}e^{ax+by} = \frac{1}{5} \cdot \frac{x}{1}e^{3x+y} = \frac{x}{5}e^{3x+y} \]
\[ \therefore z = z_1 + z_2 \]
\[ = \phi_1(y + 3x) + \phi_2(y - 2x) + \frac{x}{5}e^{3x+y} \]

Where \( \phi_1 \) and \( \phi_2 \) are arbitrary functions

**Case 2** when \( f(x, y) = \sin(ax + by) \) or \( \cos(ax + by) \)

where \( a \) and \( b \) are arbitrary constant

Here, we will find the P.I. of (H.L.P.D.E.) of order 2 only, by the same way that in case 1 we will derive \( f(x, y) \) for \( x \) and \( y \).

Let \( f(x, y) = \sin(ax + by) \)

\[ D_x\sin(ax + by) = a \cos(ax + by) \]
\[ D_x^2 \sin(ax + by) = -a^2 \sin(ax + by) \]
\[ D_y \sin(ax + by) = b \cos(ax + by) \]
\[ D_y^2 \sin(ax + by) = -b^2 \sin(ax + by) \]
\[ D_xD_y \sin(ax + by) = D_x[b \cos(ax + by)] \]
\[ = -ab \sin(ax + by) \]
\[ F(D_x^2, D_xD_y, D_y^2) \sin(ax + by) = F(-a^2, -ab, -b^2) \sin(ax + by) \]

Multiplying both sides by \( \frac{1}{F(D_x^2, D_xD_y, D_y^2)} \)
\[
\sin(ax + by) = \frac{1}{F(D_x^2, D_x D_y, D_y^2)} F(-a^2, -ab, -b^2) \sin(ax + by)
\]

If \[F(-a^2, -ab, -b^2) \neq 0\] then we can divide on it
\[
\rightarrow z = \frac{1}{F(D_x^2, D_x D_y, D_y^2)} \sin(ax + by)
\]
\[
= \frac{1}{F(-a^2, -ab, -b^2)} \sin(ax + by)
\]

Which it is the particular integral.

And if \[F(-a^2, -ab, -b^2) = 0\] then we write
\[
\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i}, \quad \cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2}
\]

And follow the solution of the exponential function in case 1.

**Ex.4: Solve** \((D_x^2 - D_x D_y - 6D_y^2)z = \sin(2x - 3y)\)

**Sol.**

1) The general solution \(z_1\) is the same in Ex.2

2) The P.I. \(z_2\)

\[
a = 2, \quad b = -3
\]
\[
F(-a^2, -ab, -b^2) = -a^2 + ab + 6b^2
\]
\[
F(-4, 6, -9) = -4 - 6 + 54 = 44 \neq 0
\]
\[
z_2 = \frac{1}{44} \sin(2x - 3y)
\]

The required general solution

\[
\therefore \quad z = z_1 + z_2
\]
\[
= \varphi_1(y + 3x) + \varphi_2(y - 2x) + \frac{1}{44} \sin(2x - 3y)
\]
Where $\phi_1$ and $\phi_2$ are arbitrary functions.

**Ex. 5:** Solve $(D_x^2 - 3D_xD_y + D_y^2)z = e^{2x+3y} + e^{x+y} + \sin(x - 2y)$

**Sol.**

1) Finding the general solution $z_1$

The A.E. is

$$m^2 - 3m + 2 = 0 \implies (m - 2)(m - 1) = 0$$

$$\therefore m_1 = 2, m_2 = 1$$

$$z_1 = \phi_1(y + 2x) + \phi_2(y + x)$$

where $\phi_1$ and $\phi_2$ are arbitrary functions.

2) The P.I. of the given equation is

$$\text{P.I.} = z_2 = \frac{1}{F(D_x,D_y)} e^{2x+3y} + \frac{1}{F(D_x,D_y)} e^{x+y} + \frac{1}{F(D_x,D_y)} \sin(x - 2y)$$

Let $u_1 = \frac{1}{F(D_x,D_y)} e^{2x+3y}$, $a = 2, b = 3$

$F(D_x,D_y) = a^2 - 3ab + 2b^2$

$F(1,1) = 4 - 18 + 18 = 4 \neq 0$

$$u_1 = \frac{1}{4} e^{2x+3y}$$

Let $u_2 = \frac{1}{F(D_x,D_y)} e^{x+y}$, $a = 1, b = 1$

$F(D_x,D_y) = a^2 - 3ab + 2b^2$

$F(1,1) = 1 - 3 + 2 = 0$

Analyze $F(D_x,D_y)$,

$F(D_x,D_y) = (D_x - 2D_y)(D_x - D_y)$

$$u_2 = \frac{1}{G(a,b)} \frac{x^r}{r!} e^{ax+by}$$
Chapter One: Methods of solving partial differential equations

The required general solution is

\[ u_2 = -x e^{x+y} \]

\[ u_3 = \frac{1}{F(D_x, D_y)} \sin(x - 2y) \]

\[ F(-a^2, -ab, -b^2) = -a^2 + 3ab - 2b^2 \]

\[ F(-1,2, -4) = -1 - 6 - 8 = -15 \neq 0 \]

\[ u_3 = \frac{1}{-15} \sin(x - 2y) \]

Then, the required general solution is

\[ z = z_1 + z_2 = \phi_1(y + 2x) + \phi_2(y + x) + \frac{1}{4} e^{2x+3y} - x e^{x+y} - \frac{1}{15} \sin(x - 2y) \]

where \( \phi_1 \) and \( \phi_2 \) are arbitrary functions.

**Ex. 6:** Find the P.I. of the equation

\[ (D_x^2 - 4D_xD_y + 3D_y^2)z = \cos(x + y) \]

**Sol.** \( a = 1, b = 1 \)

\[ F(-a^2, -ab, -b^2) = -a^2 + 4ab - 3b^2 \]

\[ F(-1, -1, -1) = -1 + 4 - 3 = 0 \]

Taking \( \cos(x + y) = \frac{e^{ix+iy}+e^{-ix-iy}}{2} \)

\[ z = \frac{1}{2} \left[ \frac{1}{D_x^2 - 4D_xD_y + 3D_y^2} e^{ix+iy} + \frac{1}{D_x^2 - 4D_xD_y + 3D_y^2} e^{-ix-iy} \right] \]

Let \( u_1 = \frac{1}{D_x^2 - 4D_xD_y + 3D_y^2} e^{ix+iy} \)

To find \( u_1 a = i, b = i \)

\[ F(a, b) = a^2 - 4ab + 3b^2 \]
Chapter One: Methods of solving partial differential equations

\[ F(i, i) = i^2 - 4i^2 + 3i^2 = 0 \]

Analyze \( F(D_x, D_y) \),

\[ F(D_x, D_y) = (D_x - D_y)(D_x - 3D_y) \]

\[ u_1 = \frac{1}{-2i} x e^{ix+iy} \]

By the same way \( u_2 = \frac{1}{2i} x e^{-ix-iy} \)

\[
\therefore z = \frac{1}{2} \left[ \frac{1}{-2i} x e^{ix+iy} + \frac{1}{2i} x e^{-ix-iy} \right]
\]

\[ = \frac{-x}{2} \left[ \frac{e^{ix+iy} - e^{-ix-iy}}{2i} \right] = \frac{-x}{2} \sin(x + y) \text{which is the P.I.} \]

**Case 3** When \( f(x, y) = x^a y^b \) where \( a \) and \( b \) are Non-Negative Integer Number

The particular integral (P.I.) is evaluated by expanding the function \( \frac{1}{F(D_x, D_y)} \) in an infinite series of ascending powers of \( D_x \) or \( D_y \) (i.e.) by transfer the function \( \frac{1}{F(D_x, D_y)} \) according to the following

\[ \frac{1}{1 - \theta} = 1 + \theta + \theta^2 + \cdots \]

**Ex.7:** Find P.I. of the equation \( (D_x^2 - 2D_x D_y)z = x^3 y \)

**Sol.** P.I. \( = \frac{1}{D_x^2 - 2D_x D_y} x^3 y \)
Chapter One: Methods of solving partial differential equations

\[
\frac{1}{D_x^2 (1 - 2 \frac{D_y}{D_x})} x^3 y D_y^m y^m = 0 \text{ if } n > m
\]

\[
= \frac{1}{D_x^2} \left[ 1 + 2 \frac{D_y}{D_x} + \frac{4 D_y^2}{D_x^2} + \cdots \right] x^3 y, \quad \frac{4 D_y^2}{D_x^2} = 0
\]

\[
= \frac{1}{D_x^2} \left[ x^3 y + \frac{x^4}{2} \right]
\]

\[
= \frac{1}{D_x} \left[ \frac{x^4 y}{4} + \frac{x^5}{10} \right] = \frac{x^5 y}{20} + \frac{x^6}{60}
\]

**Ex.8:** Find P.I. of the equation \((D_x^3 - 7D_x D_y^2 - 6D_y^3)z = x^2 y\)

**Sol.**

\[
P.I. = \frac{1}{D_x^3 - 7D_x D_y^2 - 6D_y^3} x^2 y
\]

\[
= \frac{1}{D_x^3} \left[ 1 - \left( \frac{7 D_y^2}{D_x^2} + \frac{6 D_y^3}{D_x^3} \right) \right] x^2 y
\]

\[
= \frac{1}{D_x^3} \left[ 1 + \left( \frac{7 D_y^2}{D_x^2} + \frac{6 D_y^3}{D_x^3} \right) + \left( \frac{7 D_y^2}{D_x^2} + \frac{6 D_y^3}{D_x^3} \right)^2 + \cdots \right] x^2 y
\]

\[
= \frac{1}{D_x^3} [x^2 y]\text{ since } \left( \frac{7 D_y^2}{D_x^2} + \frac{6 D_y^3}{D_x^3} \right) = 0, \left( \frac{7 D_y^2}{D_x^2} + \frac{6 D_y^3}{D_x^3} \right)^2 = 0
\]

\[
= \frac{x^3 y}{3} = \frac{x^4 y}{12} = \frac{x^5 y}{60}
\]

**Ex.9:** Solve \((D_x^3 - \alpha^2 D_x D_y^2)z = x\), where \(\alpha \in \mathbb{R}\)

**Sol.**

1) the general solution \(z_1\)

The A.E. of the given equation is

\[
m^3 - \alpha^2 m = 0 \implies m(m^2 - \alpha^2) = 0
\]

\[
\implies m(m - \alpha)(m + \alpha) = 0
\]
\[ m_1 = 0, m_2 = a, m_3 = -a \quad \text{(different roots)} \quad \therefore z_1 = \phi_1(y) + \phi_2(y + ax) + \phi_3(y - ax) \]

where \( \phi_1, \phi_2 \) and \( \phi_3 \) are arbitrary functions.

2) The P.I. of the given equation is

\[
P.I. = z_2 = \frac{1}{D_x^3 - a^2 D_x D_y^2} x
\]

\[
= \frac{1}{D_x^3 \left[ 1 - \frac{a^2 D_y^2}{D_x^2} \right]} x
\]

\[
= \frac{1}{D_x^3} \left[ 1 + a^2 D_y^2 + \left( \frac{a^2 D_y^2}{D_x^2} \right)^2 + \cdots \right] x \left( \frac{a^2 D_y^2}{D_x^2} = 0, \left( \frac{a^2 D_y^2}{D_x^2} \right)^2 = 0 \right)
\]

\[
= \frac{1}{D_x^3} [x]
\]

\[
= \frac{1}{D_x^2} \left[ \frac{x^2}{2} \right]
\]

\[
= \frac{1}{D_x} \left[ \frac{x^3}{6} \right] = \frac{x^4}{24}
\]

then, the required general solution is

\[
z = z_1 + z_2 = \phi_1(y) + \phi_2(y + ax) + \phi_3(y - ax) + \frac{x^4}{24}
\]

**Case 4** When \( f(x, y) = e^{ax+by}V \) where \( V \) is a function of \( x \) and \( y \)

The P.I. in this case is \( z = \frac{1}{F(D_x, D_y)} e^{ax+by} V \)

\[
= e^{ax+by} \frac{1}{F(D_x + a, D_y + b)} V
\]
and solving this equation depending on the type of \( V \) can get the particular integral (P.I.), as follows:

**Ex.10: Find P.I. of the equation** \( D_xD_yz = e^{2x+3y}x^2y \)

**Sol.**

\[
P.I. = \frac{1}{D_xD_y} e^{2x+3y}x^2ya = 2, b = 3 \text{ and } V = x^2y
\]

\[
= e^{2x+3y} \frac{1}{(D_x+2)(D_y+3)} x^2y
\]

\[
= e^{2x+3y} \frac{1}{3(D_x + 2)} \left[ 1 - \frac{D_y}{3} + \frac{D_y^2}{9} - \cdots \right] x^2y
\]

\[
= e^{2x+3y} \frac{1}{6(1 + \frac{D_x}{2})} \left[ x^2y - \frac{x^3}{3} \right]
\]

\[
= \frac{1}{6} e^{2x+3y} \left[ 1 - \frac{D_x}{2} + \frac{D_x^2}{4} - \frac{D_x^3}{8} + \cdots \right] \left[ x^2y - \frac{x^3}{3} \right], \quad (\frac{D_x^3}{8} = 0)
\]

\[
= \frac{1}{6} e^{2x+3y} \left[ x^2y - \frac{x^3}{3} - xy + \frac{x}{2} + \frac{y}{2} - \frac{1}{6} \right]
\]

\[
= e^{2x+3y} \left[ \frac{1}{6} x^2y - \frac{x^3}{18} - \frac{1}{6} xy + \frac{x}{18} + \frac{y}{12} - \frac{1}{36} \right]
\]

**Ex.11: Find P.I. of the equation** \( (D_x^2 - D_xD_y)z = e^{x+y}xy^2 \)

**Sol.**

\[
P.I. = \frac{1}{D_x^2 - D_xD_y} e^{x+y}xy^2a = 1, b = 1 \text{ and } V = xy^2
\]

\[
= e^{x+y} \frac{1}{(D_x+1)(D_x-D_y)} xy^2 \text{ since } D_x^2 - D_xD_y = D_x(D_x - D_y)
\]
Chapter One: Methods of solving partial differential equations

\[ e^{x+y} \frac{1}{(D_x + 1)D_x(1 - \frac{D_y}{D_x})} \ xy^2 \]

\[ = e^{x+y} \frac{1}{(D_x + 1)D_x} \left[ 1 + \frac{D_y}{D_x} + \frac{D_y^2}{D_x^2} + \cdots \right] xy^2 \]

\[ = e^{x+y} \frac{1}{(D_x + 1)D_x} \left[ xy^2 + \frac{2xy}{D_x} + \frac{2x}{D_x^2} \right] \]

\[ = e^{x+y} \frac{1}{(D_x + 1)D_x} \left[ xy^2 + x^2y + \frac{x^3}{3} \right] \]

\[ = e^{x+y} \frac{1}{(D_x + 1)} \left[ \frac{x^2y^2}{2} + \frac{x^3y}{3} + \frac{x^4}{12} \right] \]

\[ = e^{x+y} \left[ 1 - D_x + D_x^2 - D_x^3 + D_x^4 - D_x^5 + \cdots \right] \left[ \frac{x^2y^2}{2} + \frac{x^3y}{3} + \frac{x^4}{12} \right] \]

where \( D_x^5 = 0 \)

\[ = e^{x+y} \left[ \frac{x^2y^2}{2} + \frac{x^3y}{3} + \frac{x^4}{12} - xy^2 - x^2y - \frac{x^3}{3} + y^2 + 2xy + x^2 - 2y - 2x + 2 \right] \]

**Ex. 12:** Find P.I. of the equation \((D_x - D_y)^2z = e^{x+y} \sin(x + 2y)\)

**Sol.** P.I. = \[ \frac{1}{(D_x - D_y)^2} e^{x+y} \sin(x + 2y) \] \(a_1 = 1, b_1 = 1\)

\[ = e^{x+y} \frac{1}{(D_x + 1 - D_y - x)^2} \sin(x + 2y) \]

\[ = e^{x+y} \frac{1}{(D_x - D_y)^2} \sin(x + 2y) \]

\[ = e^{x+y} \frac{1}{D_x^2 - 2D_xD_y + D_y^2} \sin(x + 2y) \] \(a_2 = 1, b_2 = 2\)

\[ F(-a_2^2, -a_2b_2, -b_2^2) = -a_2^2 + 2a_2b_2 - b_2^2 \]

\[ F(-1, -2, -4) = -1 + 4 - 4 = -1 \neq 0 \]
Chapter One: Methods of solving partial differential equations

\[ z = e^{x+y} \cdot \frac{1}{-1} \sin(x + y) \Rightarrow z = -e^{x+y} \sin(x + y) \]

**Case 5** When \( f(x, y) = g(ax + by) \) where \( F(a, b) \neq 0 \)

The particular integral of H.L.P.D.E. of order \( n \) is

\[ z = \frac{1}{F(a,b)} \int_{n-\text{times}} g(ax + by) \, d(ax + by) \ldots d(ax + by) \]

**Ex.13: Find P.I. of** \( (D_x^2 + 2D_xD_y - 8D_y^2)z = \sqrt{2x + 3y} \)

**Sol.**

\[ a = 2, b = 3 \; , \; g(2x + 3y) = \sqrt{2x + 3y} \]

\[ F(a, b) = a^2 + 2ab - 8b^2 \]

\[ F(2,3) = 4 + 12 - 72 = -56 = 0 \; , \; \text{integrating } g \; \text{twice} \]

\[ \therefore \text{P.I.} = z = \frac{1}{-56} \iint \sqrt{2x + 3y} \, d(2x + 3y) \, d(2x + 3y) \]

\[ = \frac{1}{-56} \int_3^2 (2x + 3y)^{3/2} \, d(2x + 3y) \]

\[ = \frac{4}{-56(15)} (2x + 3y)^{5/2} \]

\[ = -\frac{1}{210} (2x + 3y)^{5/2} \]

**Case 6** When \( f(x, y) = g(ax + by) \) where \( F(a, b) = 0 \)

If \( F(a,b) = 0 \), then \( F(D_x, D_y) \) can be written as

\[ F(D_x, D_y) = (bD_x - aD_y)^n \]
and the particular solution is \[ Z = \frac{x^n g(ax+by)}{n!} b^n \]

**Ex.14:** Find P.I. of \( (D_x^2 - 6D_xD_y + 9D_y^2)z = 3x + y \)

**Sol.** \( a = 3, b = 1 \) , \( g(3x + y) = 3x + y \)
\[ F(a, b) = a^2 - 6ab + 9b^2 \]
\[ F(3,1) = 9 - 18 + 9 = 0 \]
Then \( F(D_x, D_y) = D_x^2 - 6D_xD_y + 9D_y^2 = (D_x - 3D_y)^2 \) , so \( n = 2 \)
\[ \therefore P.I. = z = \frac{x^23x+y}{2!} = \frac{1}{2} x^2 (3x + y) \]

**Ex.15:** Find P.I. of \( (D_x^2 - 4D_xD_y + 4D_y^2)z = \tan(2x + y) \)

**Sol.** \( a = 2, b = 1 \) , \( g(2x + y) = \tan(2x + y) \)
\[ F(a, b) = a^2 - 4ab + 4b^2 \]
\[ F(2,1) = 4 - 8 + 4 = 0 \]
Then \( F(D_x, D_y) = D_x^2 - 4D_xD_y + 4D_y^2 = (D_x - 2D_y)^2 \) , so \( n = 2 \)
\[ \therefore P.I. = z = \frac{x^2\tan(2x+y)}{2!} = \frac{1}{2} x^2 \tan(2x + y) \]

**Ex.16:** Find P.I. of \( (D_x^2 - D_y^2)z = \sec^2(x + y) \)

**Sol.** \( a = 1, b = 1 \) , \( g(x + y) = \sec^2(x + y) \)
\[ F(a, b) = a^2 - b^2 \]
\[ F(1,1) = 1 - 1 = 0 \]
Then \( F(D_x, D_y) = D_x^2 - D_y^2 = (D_x - D_y)(D_x + D_y) \)
\[ \therefore z = \frac{1}{(D_x - D_y)(D_x + D_y)} \sec^2(x + y) \]
Let \( u_1 = \frac{1}{(D_x+D_y)} \sec^2(x + y) \) by case (5) we have
\[ u_1 = \frac{1}{F(a,b)} \int g(ax + by) \, d(ax + by), \quad F(1,1) = 1 + 1 = 2 \]
\[ = \frac{1}{2} \int \sec^2(x + y) \, d(x + y) \]
\[ = \frac{1}{2} \tan(x + y) \]
\[ \Rightarrow z = \frac{1}{(D_x - D_y)^2} \frac{1}{2} \tan(x + y) \]
\[ F(D_x, D_y) = D_x - D_y \]
\[ F(1,1) = 1 - 1 = 0 \]
where \( n = 1 \)
\[ \therefore z = \frac{x^1 \tan(x + y)}{1! \cdot 2} \]
\[ = \frac{x}{2} \tan(x + y) \quad \text{which its' the particular integral} \]

...General Exercises ...

1. \((D_x^4 - D_y^4)z = 0\)
2. \((D_x^3 - 7D_xD_y - 6D_y^3)z = \cos(x - y) + x^2 + xy^2 + y^2\)

Section(2.1): Non-homogeneous linear partial differential equations with constant coefficients

**Definition:** A linear partial differential equation with constant coefficients is known as non-homogeneous l.p.d.e. with constant coefficients if the order of all the partial derivatives involved in the equation are not all equal.

For example:

1) \( \frac{\partial^2 z}{\partial x^2} + \frac{\partial z}{\partial y} + z = x + y \)

2) \( \frac{\partial^3 z}{\partial x^3} + \frac{\partial^2 z}{\partial x \partial y} + \frac{\partial z}{\partial y} = e^{x+y} \)

**Definition:** A linear differential operator \( F(D_x, D_y) \) is known as (reducible), if it can be written as the product of linear factors of the form \( aD_x + bD_y + c \) with \( a, b \) and \( c \) as constants. \( F(D_x, D_y) \) is known as (irreducible), if it is not reducible.

For example:

The operator \( D_x^2 - D_y^2 \) which can be written in the form \( (D_x - D_y)(D_x + D_y) \) is reducible, whereas the operator \( D_x^2 - D_y^3 \) which cannot be decomposed into linear factors is irreducible.

**Note:** A l.p.d.e with constant coefficient \( F(D_x, D_y)z = f(x, y) \) is known as reducible, if \( F(D_x, D_y) \) reducible, and is known as irreducible, if \( F(D_x, D_y) \) is irreducible.
(2.1.1) Determination of Complementary function (C.F.) (the general solution) of a reducible non-homogeneous linear partial differential equation with constant coefficients

Let \( F(D_x, D_y) = (aD_x + bD_y + c)^k \), where \( a, b, c \) are constants and \( k \) is a natural number.

Then the equation \( F(D_x, D_y)z = 0 \) will be

\[(aD_x + bD_y + c)^k z = 0 \]

and the solution is

\[ z = e^{-\frac{c}{a}x} \phi(ay - bx) \quad ; \quad a \neq 0 \quad , k = 1 \]

Or

\[ z = e^{-\frac{c}{b}y} \phi(ay - bx) \quad ; \quad b \neq 0 \quad , k = 1 \]

For any \( k > 1 \), the solution is

\[ z = e^{-\frac{c}{b}y} [\phi_1(ay - bx) + x\phi_2(ay - bx) + \cdots + x^{k-1}\phi_k(ay - bx)] ; b \neq 0 \]

Or

\[ z = e^{-\frac{c}{a}x} [\phi_1(ay - bx) + x\phi_2(ay - bx) + \cdots + x^{k-1}\phi_k(ay - bx)] ; a \neq 0 \]

Where \( \phi_1, \ldots, \phi_n \) are arbitrary functions.

**Ex.1:** Solve \((2D_x - 3D_y - 5)z = 0\)

Sol. The given equation is linear in \( F(D_x, D_y) \)

Then \( a = 2, b = -3, c = -5, k = 1 \)

The general solution is

\[ z = e^{\frac{5}{2}x} \phi(2y + 3x) \]

Where \( \phi \) is an arbitrary function.
**Ex.2:** Solve \((D_x - 5)z = e^{x+y}\)

Sol. To find the general solution of \((D_x - 5)z = 0\)

We have \(a = 1, b = 0, c = -5, k = 1\)

\[ \therefore z_1 = e^{5x} \varnothing(y), \text{ Where } \varnothing \text{ is an arbitrary function.} \]

To find the P.I. \(z_2\), we have \(a = 1, b = 1\)

\[ F(a,b) = a - 5 \rightarrow F(1,1) = 1 - 5 = -4 \neq 0 \]

\[ \therefore z_2 = \frac{1}{-4} e^{x+y} \]

Then the required general solution of the given equation is

\[ z = z_1 + z_2 \rightarrow z = e^{5x} \varnothing(y) - \frac{1}{4} e^{x+y} \]

**Ex.3:** Solve \((2D_y + 5)^2 z = 0\)

Sol. The given equation is reducible, then

\(a = 0, b = 2, c = 5, k = 2\).

The general solution is

\[ z = e^{-\frac{5}{2}y} [\varnothing_1(-2x) + x \varnothing_2(-2x)] \]

Where \(\varnothing_1\) and \(\varnothing_2\) are arbitrary functions.

**Ex.4:** Solve \((D_x - 2D_y + 1)^4 z = 0\)

Sol. We have \(a = 1, b = -2, c = 1, k = 4\)

then

\[ z = e^{\frac{1}{2}y} [\varnothing_1(y+2x) + x \varnothing_2(y+2x) + x^2 \varnothing_3(y+2x) + x^3 \varnothing_4(y+2x)] \]

Where \(\varnothing_1, ..., \varnothing_4\) are arbitrary functions.
when \( F(D_x, D_y) \) can be written as the product of linear factors of the form \((aD_x + bD_y + c)\), i.e. \( F(D_x, D_y) \) is reducible, then the general solution is the sum of the solutions corresponding to each factor.

**Ex.5:** solve \( (2D_x - 3D_y + 1)(D_x + 2D_y - 2)z = 0 \)

\[
\begin{align*}
\text{linear} & \quad \text{linear} \\
\end{align*}
\]

Sol. The given equation is reducible, then we have

\[
\begin{align*}
a_1 &= 2, \\ b_1 &= -3, \\ c_1 &= 1, \\ k_1 &= 1 \\
z_1 &= e^{\frac{-1}{2}x}\phi_1(2y + 3x) \\
a_2 &= 1, \\ b_2 &= 2, \\ c_2 &= -2, \\ k_2 &= 1 \\
z_2 &= e^{2x}\phi_2(y - 2x)
\end{align*}
\]

The general solution is

\[
z = z_1 + z_2 \rightarrow z = e^{\frac{-1}{2}x}\phi_1(2y + 3x) + e^{2x}\phi_2(y - 2x)
\]

Where \( \phi_1, \phi_2 \) are two arbitrary functions.

**Ex.6:** solve \( D_x(D_x + D_y + 1)(D_x + 3D_y - 2)z = 0 \)

Sol. We have

\[
\begin{align*}
a_1 &= 1, \\ b_1 &= 0, \\ c_1 &= 0, \\ k_1 &= 1 \\
a_2 &= 1, \\ b_2 &= 1, \\ c_2 &= 1, \\ k_2 &= 1 \\
a_3 &= 1, \\ b_3 &= 3, \\ c_3 &= -2, \\ k_3 &= 1
\end{align*}
\]

Then the general solution is

\[
z = \phi_1(y) + e^{-x}\phi_2(y - x) + e^{2x}\phi_3(y - 3x)
\]
Chapter Two: Non-homogeneous Linear Partial Differential Equations

Where \( \phi_1, ..., \phi_3 \) are arbitrary functions.

**Ex.7:** solve \((D_x^3 - D_xD_y^2 - D_x^2 + D_xD_y)z = 0\)

Sol. We have , \((D_x^3 - D_xD_y^2 - D_x^2 + D_xD_y)z = 0\)
\[
D_x(D_x^2 - D_x^2 - D_x + D_y)z = 0 \\
D_x[(D_x - D_y)(D_x + D_y) - (D_x - D_y)] = 0 \\
D_x(D_x - D_y)(D_x + D_y - 1)z = 0
\]
Then , \(a_1 = 1, b_1 = 0, c_1 = 0, k_1 = 1\)
\[
a_2 = 1, b_2 = -1, c_2 = 0, k_2 = 1 \\
a_3 = 1, b_3 = 1, c_3 = -1, k_3 = 1
\]
Then the general solution is
\[
z = \phi_1(y) + \phi_2(y + x) + e^x \phi_3(y - x)
\]
Where \( \phi_1, ..., \phi_3 \) are arbitrary functions.

**C** When \(F(D_x, D_y)\) is irreducible then the general solution is
\[
z = \sum_{i=1}^{\infty} A_i e^{a_i x + b_i y}
\]
Where \(F(a_i, b_i) = 0, A_i, a_i, b_i\) are all constants.

**Ex.8:** Solve \((D_x - D_y^3)z = 0\)

Sol. The given equation is irreducible, then
\[
F(a, b) = 0 \quad \rightarrow \quad F(a_i, b_i) = 0 \\
a - b^3 = 0 \quad \rightarrow \quad a_i - b_i^3 = 0 \quad \rightarrow \quad a_i = b_i^3
\]
The general solution is
\[
z = \sum_{i=1}^{\infty} A_i e^{a_i x + b_i y} = \sum_{i=1}^{\infty} A_i e^{b_i^3 x + b_i y}
\]
Where $A_i, b_i$ are constants.

**Ex.9: Solve** $(D_x^2 + D_x + D_y)z = 0$

Sol. The given equation is irreducible, then

$$F(a, b) = a^2 + a + b = 0 \rightarrow a_i^2 + a_i + b_i = 0$$

$$\rightarrow b_i = -a_i^2 - a_i$$

The general solution is

$$z = \sum_{i=1}^{\infty} A_i e^{a_i x + b_i y} = \sum_{i=1}^{\infty} A_i e^{a_i x + (-a_i^2 - a_i) y}$$

Where $A_i, a_i$ are constants.

**Ex.10: Solve** $(D_x - D_y^2)z = e^{2x+3y}$

Sol. (1) we find the general solution of the irreducible equation

$$(D_x - D_y^2)z = 0$$

$$F(a, b) = a - b^2 = 0 \rightarrow F(a_i, b_i) = a_i - b_i^2 = 0 \rightarrow a_i$$

$$= b_i^2$$

Then

$$z_1 = \sum_{i=1}^{\infty} A_i e^{a_i x + b_i y} = \sum_{i=1}^{\infty} A_i e^{b_i^2 x + b_i y}$$

Where $A_i, b_i$ are constants.

(2) The P.I. is

$$F(a, b) = a - b^2$$

$$\therefore F(2,3) = 2 - 9 = -7 \neq 0$$

$$\therefore z_2 = \frac{1}{-7} e^{2x+3y}$$
And the required general solution is

\[ z = z_1 + z_2 = \sum_{i=1}^{\infty} A_i e^{b_i^2 x + b_i y} - \frac{1}{7} e^{2x+3y} \]

(D) When \( F(D_x, D_y) \) can be written as the product of linear and non-linear factors the general solution is the sum of the solutions corresponding to each factor.

**Ex.11:** Solve \( (D_x + 2D_y)(D_x - 2D_y + 1)(D_x - D_y^2)z = 0 \)

Sol:

Factor 1, \( a_1 = 1, b_1 = 2, c_1 = 0, k_1 = 1 \)

Factor 2, \( a_2 = 1, b_2 = -2, c_2 = 1, k_2 = 1 \)

Factor 3, \( F(a, b) = a - b^2 = 0 \rightarrow a = b^2 \rightarrow a_i = b_i^2 \)

\[ \therefore z = \phi_1(y - 2x) + e^{\frac{1}{2}y}\phi_2(y + 2x) + \sum_{i=1}^{\infty} A_i e^{b_i^2 x + b_i y} \]

Where \( \phi_1, \phi_2 \) are arbitrary functions and \( A_i, b_i \) are constants.

**Ex.12:** Solve \( (D_x^2 - D_y^2 + D_x)z = x^2 + 2y \)

Sol: (1) The general solution of \( (D_x^2 - D_y^2 + D_x)z = 0 \) is

\[ F(a, b) = a^2 - b^2 + a = 0 \rightarrow b = \pm \sqrt{a^2 + a} \rightarrow b_i = \pm \sqrt{a_i^2 + a_i} \]

Then

\[ z_1 = \sum_{i=1}^{\infty} A_i e^{a_i x \pm \sqrt{a_i^2 + a_i} y} \]

(2) The P.I. is
Chapter Two: Non-homogeneous Linear Partial Differential Equations

\[ z_1 = \frac{1}{D_x^2 - D_y^2 + D_x} (x^2 + 2y) \]

\[ = \frac{1}{D_x(1 + D_x - \frac{D_y^2}{D_x})} (x^2 + 2y) \]

\[ = \frac{1}{D_x[1 - \left(\frac{D_y^2}{D_x} - D_x\right)]} (x^2 + 2y) \]

\[ = \frac{1}{D_x}[1 + \frac{D_y^2}{D_x} - D_x + \left(\frac{D_y^2}{D_x} - D_x\right)^2 + \ldots] (x^2 + 2y) \]

\[ = \frac{1}{D_x}[x^2 + 2y - 2x + 2] = \frac{x^3}{3} + 2xy - x^2 + 2x \]

The required general solution is

\[ z = z_1 + z_2 = \sum_{i=1}^{\infty} A_i e^{a_ix + \sqrt{a_i^2 + a_iy}} + \frac{x^3}{3} + 2xy - x^2 + 2x \]

Ex.13: Solve \((2D_x + 3D_y)(3D_x - 4D_y + 5)(3D_x - D_y^2)z = 0\)

Sol:

Factor 1, \(a_1 = 2, b_1 = 3, c_1 = 0, k_1 = 1\)

Factor 2, \(a_2 = 3, b_2 = -4, c_2 = 5, k_2 = 1\)

Factor 3, \(F(a, b) = 3a - b^2 = 0 \quad \Rightarrow a = \frac{b^2}{3} \quad \Rightarrow a_i = \frac{b_i^2}{3}\)

The general solution is

\[ \therefore z = \phi_1(2y - 3x) + e^{\frac{5}{4}y}\phi_2(3y + 4x) + \sum_{i=1}^{\infty} A_i e^{\frac{b_i^2}{3}x + b_iy} \]
Where $\phi_1, \phi_2$ are arbitrary functions and $A_i, b_i$ are constants.

**Note** To determine the P.I. of non-homo.p.d.e. when

$$f(x, y) = \sin(ax + by) \quad \text{or} \quad \cos(ax + by)$$

we put $D^2 = -a^2$, $D_y^2 = -b^2$, $D_xD_y = -ab$, which provided the denominator is non-zero, as follows.

**Ex.14: Solve** $(D_x^2 - D_y)z = \sin(x - 2y)$

Sol: (1) The general solution $z_1$ of $(D_x^2 - D_y)z = 0$ is

$$F(a, b) = a^2 - b = 0 \quad \rightarrow \quad a_i^2 = b_i$$

$$z_1 = \sum_{i=1}^{\infty} A_i e^{a_ix + a^2_i y}$$

(2) To find the P.I. of the given equation

$$P.I. = z = \frac{1}{D_x^2 - D_y} \sin(x - 2y)$$

$$a = 1, \quad b = -2 \quad \rightarrow \quad D_x^2 = -a^2 = -1$$

$$= \frac{1}{-1 - D_y} \sin(x - 2y)$$

Multiplying by $\frac{1}{-1 + D_y}$

$$= \frac{-1 + D_y}{1 - D_y^2} \sin(x - 2y)$$

$$D_y^2 = -b^2 = -4$$

$$= \frac{-1 + D_y}{1 + 4} \sin(x - 2y)$$
\[
\frac{1}{5}[-\sin(x - 2y) - 2\cos(x - 2y)]
\]

...Exercises...

Solve the following equations:

1. \((D_x^2 + D_x D_y + D_y - 1)z = 0\)
2. \((D_x + 1)(D_x - D_y + 1)z = 0\)
3. \((D_x^2 + D_x D_y + D_x)z = 0\)
4. \((D_x^2 + D_y + 4)z = e^{4x-y}\)
5. \((D_x^2 + D_x D_y + D_y - 1)z = \sin(x + 2y)\)
6. \((D_x - D_y - 1)(D_x - D_y - 2)z = x\)
7. \((D_x^2 - D_y^2 + D_x + 3D_y - 2)z = x^2 y\)
8. \((D_x + 3D_y - 2)^2 z = 2e^{2x}\sin(y + 3x)\)
Section(2.2): Partial differential equations of order two with variable coefficients

In the present section, we propose to discuss partial differential equations of order two with variable coefficients. An equation is said to be of order two, if it involves at least one of the differential coefficients \( r = \frac{\partial^2 z}{\partial x^2}, s = \frac{\partial^2 z}{\partial x \partial y}, t = \frac{\partial^2 z}{\partial y^2} \), but none of higher order, the quantities \( p \) and \( q \) may also inter into the equation. Thus the general form of a second order partial differential equation is

\[
R(x, y) \frac{\partial^2 z}{\partial x^2} + S(x, y) \frac{\partial^2 z}{\partial x \partial y} + T(x, y) \frac{\partial^2 z}{\partial y^2} + P(x, y) \frac{\partial z}{\partial x} + Q(x, y) \frac{\partial z}{\partial y} + V(x, y)z = f(x, y)
\]

...(1)

Or \( Rr + Ss + Tt + Pp + Qq + Vz = f \) ...(2)

Where \( R, S, T, P, Q, V, f \) are functions of \( x \) and \( y \) only and not all \( R, S, T \) are zero.

We will discuss three cases of the equation (2):

Case 1 when one of \( R, S, T \) not equal to zero and \( P, Q, V \) are equal to zero, then the solution can be obtained by integrating both sides of the equation directly.

Ex.15: Solve \( \frac{\partial^2 z}{\partial x^2} + 5y - x^2 y^2 = 0 \)

Sol: Given equation can be written
Chapter Two: Non-homogeneous Linear Partial Differential Equations

\[
\frac{\partial^2 z}{\partial x^2} = yx^2 - 5 \ldots (3)
\]

Integrating (3) w.r.t. \( x \)

\[
\frac{\partial z}{\partial x} = \frac{yx^3}{3} - 5x + \varphi_1(y) \ldots (4)
\]

Integrating (4) w.r.t. \( x \)

\[
z = \frac{yx^4}{12} - \frac{5}{2}x^2 + x\varphi_1(y) + \varphi_2(y)
\]

Where \( \varphi_1 \) and \( \varphi_2 \) are two arbitrary functions.

**Ex.16: Solve** \( xy \frac{\partial^2 z}{\partial x \partial y} - y^2 x = 0 \)

Sol: Given equation can be written

\[
\frac{\partial^2 z}{\partial x \partial y} = y \ldots (5)
\]

Integrating (5) w.r.t. \( x \)

\[
\frac{\partial z}{\partial y} = xy + \varphi_1(y) \ldots (6)
\]

Integrating (6) w.r.t. \( y \)

\[
z = \frac{xy^2}{2} + \int \varphi_1(y) \, dy + \varphi_2(x)
\]

\[
= \frac{xy^2}{2} + \varphi(y) + \varphi_2(x)
\]

Where \( \varphi \) and \( \varphi_2 \) are two arbitrary functions.

**Case2** When all the derivatives in the equation for one independent variable i.e the equation is of the form
Some of these coefficients may be Zeros.

These equations will be treated as a ordinary linear differential equations, a follows:

**Ex.17: Solve** \( y \frac{\partial^2 z}{\partial y^2} + 3 \frac{\partial z}{\partial y} = 2x + 3 \)

**Sol:** let \( \frac{\partial z}{\partial y} = q \) \( \rightarrow \frac{\partial^2 z}{\partial y^2} = \frac{\partial q}{\partial y} \)

Substituting in the given equation, we get
\[
y \frac{\partial q}{\partial y} + 3q = 2x + 3 \quad \rightarrow \quad \frac{\partial q}{\partial y} + \frac{3}{y}q = \frac{2x+3}{y} \quad \ldots(7)
\]

Which it's linear diff. eq. in variables \( q \) and \( y \), regarding \( x \) as a constant.

Integrating factor (I.F.) of (7) = \( e^{\int \frac{3}{y} \partial y} = e^{3 \ln y} = y^3 \)

And solution of (7) is
\[
y^3 q = \int \frac{2x + 3}{y} y^3 \partial y + \phi_1(x)
\]
\[
y^3 q = (2x + 3) \frac{y^3}{3} + \phi_1(x)
\]
\[
q = \frac{2x + 3}{3} + y^{-3} \phi_1(x)
\]

\[
\frac{\partial z}{\partial y} = \frac{2x+3}{3} + y^{-3} \phi_1(x) \quad \text{, integrating w.r.t.} \ y
\]
\[
z = \frac{2x + 3}{3} y - \frac{1}{2y^2} \phi_1(x) + \phi_2(x)
\]
Where $\phi_1$ and $\phi_2$ are two arbitrary functions.

**Ex.18:** Solve $\frac{\partial^2 z}{\partial x^2} - 2y \frac{\partial z}{\partial x} + y^2 z = (y - 3)e^{2x+3y}$

**Sol:** The given equation can be written as

$$D_x^2 - 2yD_x + y^2 z = (y - 3)e^{2x+3y}$$

$\Rightarrow (D_x - y)^2 z = (y - 3)e^{2x+3y} \ldots (8)$

The A.E. of the equation $(D_x - y)^2 z = 0$ is

$$(m - y)^2 = 0 \Rightarrow m_1 = m_2 = y$$

$\therefore z_1 = \phi_1(y)e^{y_1} + x\phi_2(y)e^{y_2} \ldots (9)$

Where $\phi_1$ and $\phi_2$ are two arbitrary functions.

The P.I. $(z_2)$ is

$$z_2 = \frac{1}{(D_x - y)^2} (y - 3)e^{2x+3y} = (y - 3) \frac{1}{(2 - y)^2} e^{2x+3y}$$

$\therefore z = z_1 + z_2$

$$= \phi_1(y)e^{y_1} + x\phi_2(y)e^{y_2} + (y - 3) \frac{1}{(2 - y)^2} e^{2x+3y}$$

**Case 3** under this type, we consider equations of the form

$$Rr + Ss + Pp = f(x, y) \Rightarrow R \frac{\partial^2 z}{\partial x^2} + S \frac{\partial^2 z}{\partial x \partial y} + P \frac{\partial z}{\partial x} = f(x, y)$$

And $Ss + Tt + Qq = f(x, y) \Rightarrow S \frac{\partial^2 z}{\partial x \partial y} + T \frac{\partial^2 z}{\partial y^2} + Q \frac{\partial z}{\partial y} = f(x, y)$

These can be transform to a linear, p.d.es of order one with $p$ or $q$ as dependent variable and $x, y$ as independent variables. In such situations we shall apply well known Lagrange's method.
**Ex.19:** Solve \( x \frac{\partial^2 z}{\partial x^2} - y \frac{\partial^2 z}{\partial x \partial y} - \frac{\partial z}{\partial x} = 0 \)

Sol: let \( p = \frac{\partial z}{\partial x} \rightarrow \frac{\partial^2 z}{\partial x^2} = \frac{\partial p}{\partial x} \rightarrow \frac{\partial^2 z}{\partial x \partial y} = \frac{\partial p}{\partial y} \)

Substituting in the given equation, we get

\[
x \frac{\partial p}{\partial x} - y \frac{\partial p}{\partial y} - p = 0...(10)
\]

Which it is in Lagrange's form, the Lagrange's auxiliary equations are:

\[
\frac{dx}{x} = \frac{dy}{-y} = \frac{dp}{p}...(11)
\]

Taking the first and second fractions of (11):

\[
\frac{dx}{x} = \frac{dy}{-y} \rightarrow \ln x = -\ln y + \ln a \rightarrow xy = a...(12)
\]

Taking the first and the third fractions of (11):

\[
\frac{dx}{x} = \frac{dp}{p} \rightarrow \ln x = \ln p + \ln b \rightarrow \frac{x}{p} = b...(13)
\]

From (12) & (13), the general solution is

\[
\phi(a, b) = 0 \rightarrow \phi \left( xy, \frac{x}{p} \right) = 0 \rightarrow \frac{x}{p} = g(xy)
\]

\[
\rightarrow p = \frac{x}{g(xy)}...(14)
\]

Integrating (14) w.r.t. \( x \), we get

\[
z = \int \frac{x}{g(xy)} \, dx + \varphi(y)...(15)
\]

Where \( g \) and \( \varphi \) are two arbitrary functions.

Then (15) is the required solution of the given equation.
…Exercises…

Solve the following equations:

1)) \( \ln \left( \frac{\partial^2 z}{\partial x \partial y} \right) = x + y \)

2)) \( \frac{\partial^2 z}{\partial y^2} - x \frac{\partial z}{\partial y} = x^2 \)

3)) \( \frac{\partial^2 z}{\partial x \partial y} - \frac{\partial^2 z}{\partial y^2} = \frac{x}{y} \)

4)) \( y^2 \frac{\partial^2 z}{\partial y^2} + 2y \frac{\partial z}{\partial y} = 1 \)

Section 2.3: Partial differential equations reducible to equations with constant coefficients

In this section, we propose to discuss the method of solving the partial differential equation, which is also called Euler-Cauchy type partial differential equations of the form:

\[
a_0 x^n \frac{\partial^n z}{\partial x^n} + a_1 x^{n-1} y \frac{\partial^n z}{\partial x^{n-1} \partial y} + \cdots + a_n y^n \frac{\partial^n z}{\partial y^n} + \cdots = f(x, y)\ldots(1)
\]

i.e. all the terms of the equation of the formula \( a_r x^n y^m \frac{\partial^{n+m} z}{\partial x^n \partial y^m} \)

To solve this equation, define two new variables \( u \) and \( v \) by

\( x = e^u \) and \( y = e^v \) so that \( u = \ln x \) and \( v = \ln y \ldots(2) \)

Let \( D_u = \frac{\partial}{\partial u} \) and \( D_v = \frac{\partial}{\partial v} \)

Now, \( \frac{\partial z}{\partial x} = \frac{\partial z}{\partial u} \cdot \frac{\partial u}{\partial x} = \frac{1}{x} \cdot \frac{\partial z}{\partial u} \), using (2)

\( \therefore \frac{\partial z}{\partial u} = x \cdot \frac{\partial z}{\partial x} \rightarrow D_u z = x D_x z \ldots(3) \)
Again \( x^2 \cdot \frac{\partial^2 z}{\partial x^2} = x^2 \frac{\partial}{\partial x} \left( \frac{\partial z}{\partial x} \right) \)

\[
= x^2 \frac{\partial}{\partial x} \left( \frac{1}{x} \cdot \frac{\partial z}{\partial u} \right) \quad \text{from (3)}
\]

\[
= \frac{1}{x} \cdot \frac{\partial^2 z}{\partial x \partial u} - x^2 \cdot \frac{\partial z}{\partial u} \cdot x^{-2}
\]

\[
= x \cdot \frac{\partial^2 z}{\partial x \partial u} - \frac{\partial z}{\partial u}
\]

\[
= x \frac{\partial}{\partial u} \left( \frac{\partial z}{\partial x} \right) - \frac{\partial z}{\partial u}
\]

\[
= x \frac{\partial}{\partial u} \left( \frac{1}{x} \cdot \frac{\partial z}{\partial u} \right) - \frac{\partial z}{\partial u}
\]

\[
= \frac{1}{x} \cdot \frac{\partial^2 z}{\partial u^2} - \frac{\partial z}{\partial u}
\]

\[
= \frac{\partial^2 z}{\partial u^2} - \frac{\partial z}{\partial u}
\]

\[
\therefore x^2 D_x^2 z = D_u (D_u - 1) z
\]

And so on similarly, we have

\[
yD_y z = D_v z, \ y^2 D_y^2 z = D_v (D_v - 1) z, ...
\]

Hence

\[
x^n \frac{\partial^n z}{\partial x^n} = D_u (D_u - 1)(D_u - 2) \ldots (D_u - n + 1) z \quad \text{(4)}
\]

\[
y^m \frac{\partial^m z}{\partial y^m} = D_v (D_v - 1)(D_v - 2) \ldots (D_v - m + 1) z \quad \text{(5)}
\]
Substituting (4),(5),(6) in (1) to get an equation having constant coefficients can easily be solved by the methods of solving homo. And non-homo. Partial differential equations with constant coefficients, Finally, with help of (2), the solution is obtained in terms of old variables $x$ and $y$.

**Ex.20:** Solve $x^2 \frac{\partial^2 z}{\partial x^2} - y^2 \frac{\partial^2 z}{\partial y^2} - y \frac{\partial z}{\partial y} + x \frac{\partial z}{\partial x} = 0$

Sol: let $x = e^u$, $y = e^v$ then $u = \ln x$ and $v = \ln y$

\[
x \frac{\partial z}{\partial x} = D_u z \quad , \quad x^2 \frac{\partial^2 z}{\partial x^2} = D_u(D_u - 1) z
\]

and

\[
y \frac{\partial z}{\partial y} = D_v z \quad , \quad y^2 \frac{\partial^2 z}{\partial y^2} = D_v(D_v - 1) z
\]

Substituting (7) in the given equation,

\[
(D_u^2 - D_u - D_v^2 + D_v - D_u + D_v) z = 0
\]

\[
(D_u^2 - D_v^2) z = 0 \Rightarrow (D_u - D_v)(D_u + D_v) z = 0
\]

The A.E. is $\frac{(m - 1)(m + 1)}{m_1 = 1, m_2 = -1} = 0$

Then the general solution is

\[
z = \Phi_1(v + u) + \Phi_2(v - u)
\]

\[
= \Phi_1(ln y + \ln x) + \Phi_2(ln y - \ln x)
\]
Chapter Two: Non-homogeneous Linear Partial Differential Equations

\[
= \phi_1(lnxy) + \phi_2 \left( ln\frac{y}{x} \right)
\]

\[
= h_1(xy) + h_2 \left( \frac{y}{x} \right)
\]

Where \( h_1 \) and \( h_2 \) are two arbitrary functions.

...Exercises...

Solve the following equations:

1)) \( (x^2 D_x^2 - y^2 D_y^2 - yD_y + xD_x)z = xy \)

2)) \( (x^2 D_x^2 - 2xyD_xD_y + y^2 D_y^2 + yD_y + xD_x)z = 0 \)

3)) \( x^2 \frac{\partial^2 z}{\partial x^2} - y^2 \frac{\partial^2 z}{\partial y^2} - y \frac{\partial z}{\partial y} + x \frac{\partial z}{\partial x} = lny \)

Classification of partial differential equations of second order:

Consider a general partial differential equation of second order for a function of two independent variables $x$ and $y$ in the form

$$Au_{xx} + Bu_{xy} + Cu_{yy} + Du_x + Eu_y + Fu = G \quad (*)$$

Where $A, B, C, D, E, F, G$ are function of $x, y$ or constants.

The equation (*) is said to be

(i) Hyperbolic at a point $(x, y)$ in domain if $B^2 - 4AC > 0$.
(ii) Parabolic at a point $(x, y)$ in domain if $B^2 - 4AC = 0$.
(iii) Elliptic at a point $(x, y)$ in domain if $B^2 - 4AC < 0$.

**Ex.21: Classify the following partial differential equation**

$$2u_{xx} + 3u_{xy} = 0$$

**Sol:**

Comparing the given equation with (*), we get $A = 2, B = 3, C = 0$

$$B^2 - 4AC = 9 - 4(2)(0) = 9 > 0$$

Showing that the given equation is hyperbolic at all points.
Ex.22: Classify the following p.d.eqs.

(1) \( \frac{\partial u}{\partial t} = \alpha^2 \frac{\partial^2 u}{\partial x^2} \)
(2) \( \frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2} \)
(3) \( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \)

**Sol. (1)** Re-writing the given equation, we get
\[
\alpha^2 u_{xx} - u_t = 0
\]
Comparing with (*), we get \( A = \alpha^2, B = 0, C = 0 \)
\[
B^2 - 4AC = 0 - 4(\alpha^2)(0) = 0
\]
Showing that the given equation is Parabolic at all points.

**Sol. (2)** Re-writing the given equation, we get
\[
c^2 u_{xx} - u_{tt} = 0
\]
Comparing with (*), we get \( A = c^2, B = 0, C = -1 \)
\[
B^2 - 4AC = 0 - 4(c^2)(-1) = 4c^2 > 0
\]
Showing that the given equation is hyperbolic at all points.

**Sol. (3)** Comparing with (*), we get \( A = 1, B = 0, C = 1 \)
\[
B^2 - 4AC = 0 - 4(1)(1) = -4 < 0
\]
Then the equation is an Elliptic at all points.

...Exercises...

Classify the following equations:

1)) \( u_x - u_{xy} - u_y = 0 \)
Chapter Two: Non-homogeneous Linear Partial Differential Equations

2) \( u_{rr} - ru_{r\theta} + r^2u_{\theta\theta} = 0 \quad ; u(r, \theta) \)

3) \( z_{xx} + z_{xy} + z_y = 2x \)

4) \( xyz_{xx} - (x^2 - y^2)z_{xy} - xyz_{yy} + yz_x - xz_y = 2(x^2 - y^2) \)

5) \( x^2(y - 1) \frac{\partial^2 z}{\partial x^2} - x(y^2 - 1) \frac{\partial^2 z}{\partial x \partial y} + 4(y - 1) \frac{\partial^2 z}{\partial y^2} + xy \frac{\partial z}{\partial x} - \frac{\partial z}{\partial y} = 0 \)

6) \( u_r - u_{\theta\theta} = 5 \)

7) \( 2 \frac{\partial^2 u}{\partial x^2} + 4 \frac{\partial^2 u}{\partial x \partial y} + 4 \frac{\partial^2 u}{\partial y^2} = 2 \)

Section 2.4: Method of Lagrange multipliers

This method applies to minimize (or maximize) a function \( f(x, y, z) \) subject to the constraint \( g(x, y, z) = 0 \), construct the auxiliary function

**Discussion of the method**

Suppose we want to find the minimum (maximum) value of the function \( f(x, y, z) \) which represents the distance between the required plane \( g(x, y, z) = 0 \) and the origin and suppose that \( f \) and \( g \) having continuous first partial derivatives and ending of \( f \) is at the point \((x_0, y_0, z_0)\) which it's on the surface \( S \) that defined by \( g(x, y, z) = 0 \)
We said that \( f \) has minimum (maximum) value at the point \((x_0, y_0, z_0)\) if it satisfies the following condition

\[
\nabla f(x, y, z) = \lambda \nabla g(x, y, z) \quad \text{(1)}
\]

Where \( \lambda \) is Lagrange's multiplier, \( \nabla \) denote to the partial derivatives of \( f \) and \( g \) w.r.t. \( x, y \) and \( z \).

**Ex.23**: by using \( \nabla f(x, y, z) = \lambda \nabla g(x, y, z) \), find the point on the straight \( y = 3 - 2x \) that is nearest the origin.

**Sol.** Let \( f(x, y) = x^2 + y^2 \rightarrow \nabla f(x, y) = < 2x, 2y > \quad \text{(2)} \)

\( g(x, y) = y + 2x - 3 = 0 \rightarrow \nabla g(x, y) = < 2, 1 > \quad \text{(3)} \)

Substituting (2) & (3) in \( \nabla f(x, y, z) = \lambda \nabla g(x, y, z) \), we get

\[
< 2x, 2y > = \lambda < 2, 1 >
\]

\[
\therefore 2x = 2\lambda \& 2y = \lambda \quad \rightarrow \quad x = \lambda = 2y \quad \text{(4)}
\]

Substituting (4) in \( g(x, y) \), we have

\[
y = 3 - 4y \quad \rightarrow \quad 5y = 3 \quad \rightarrow \quad y = \frac{3}{5}
\]
Chapter Two: Non-homogeneous Linear Partial Differential Equations

Then form (4), we have \( x = \frac{6}{5} \)

\[
\therefore (x, y) = \left( \frac{6}{5}, \frac{3}{5} \right)
\]

Which it’s the point on \( y = 3 - 2x \) that is nearest the origin.

**Note**

The distance between the point \((x, y)\) on a straight and the origin is

\[
w = \sqrt{(x - x_0)^2 + (y - y_0)^2}, \quad (x_0, y_0) = (0, 0)
\]

\[
= \sqrt{x^2 + y^2}
\]

Squaring both sides, we get

\[
w^2 = x^2 + y^2 = f(x, y)
\]

**Ex.24:** Find the point on the plane \(2x - 3y + 5z = 19\) that is nearest the origin, using the method of Lagrange multiplier.

Sol. As before, let

Let \( f(x, y, z) = x^2 + y^2 + z^2 \to \nabla f(x, y, z) = \begin{pmatrix} 2x, 2y, 2z \end{pmatrix} \)

\( g(x, y, z) = 2x - 3y + 5z - 19 = 0 \to \nabla g(x, y) = \begin{pmatrix} 2, -3, 5 \end{pmatrix} \)

From the relation \( \nabla f(x, y, z) = \lambda \nabla g(x, y, z) \)

\[
\to \begin{pmatrix} 2x, 2y, 2z \end{pmatrix} = \lambda \begin{pmatrix} 2, -3, 5 \end{pmatrix}
\]

\[
\therefore 2x = 2\lambda, \quad 2y = -3\lambda, \quad 2z = 5\lambda
\]

\[
\to x = \lambda, \quad y = \frac{-3\lambda}{2}, \quad z = \frac{5\lambda}{2}
\]
Substituting this values in $g$, we get

$$2\lambda + \frac{9}{2}\lambda + \frac{25}{2}\lambda = 19 \rightarrow 38\lambda = 38 \rightarrow \lambda = 1$$

Substituting ($\lambda = 1$) in (8), we have

$$x = 1 \quad , \quad y = \frac{-3}{2} \quad , \quad z = \frac{5}{2}$$

$$\therefore p(x, y, z) = (1, \frac{-3}{2}, \frac{5}{2})$$

**Ex.25: Suppose that the temperature of metal plate is given by $T(x, y) = x^2 + 2x + y^2$. For the points $(x, y)$ on a plate ellipse defined by $x^2 + 4y^2 \leq 24$. Find minimum and maximum temperature on the plate.**

Sol. For the plate in the figure

Firstly, we will find the critical points of $T(x, y)$ in $R$

$$T(x, y) = x^2 + 2x + y^2 \rightarrow \nabla T(x, y) = <2x + 2, 2y> = <0, 0>$$

$$\therefore 2x + 2 = 0 \quad \& \quad 2y = 0 \rightarrow x = -1 \quad \& \quad y = 0$$

$$\therefore (x, y) = (-1, 0) \text{ is in } R$$

Now, using the relation $\nabla f(x, y) = \lambda \nabla g(x, y)$

$$f(x, y) = T(x, y) = x^2 + 2x + y^2 \rightarrow \nabla T(x, y) = <2x + 2, 2y>$$

$$g(x, y) = x^2 + 4y^2 - 24 \rightarrow \nabla g(x, y) = <2x, 8y>$$

$$\nabla T(x, y) = \lambda \nabla g(x, y)$$

$$<2x + 2, 2y> = \lambda <2x, 8y>$$

$$\therefore 2x + 2 = 2\lambda x ...(9) \quad \& \quad 2y = 8\lambda y ...(10)$$
Chapter Two: Non-homogeneous Linear Partial Differential Equations

\( y(2 - 8\lambda) = 0 \)

From (10) \( y = 0 \) or \( 2 - 8\lambda = 0 \rightarrow \lambda = \frac{1}{4} \)

*if \( y = 0 \) \( \rightarrow x^2 + 4(0) = 24 \rightarrow x = \pm \sqrt{24} \)

\[ \therefore (x, y) = (\sqrt{24}, 0) \text{ or } (-\sqrt{24}, 0) \]

*if \( \lambda = \frac{1}{4} \) \( \rightarrow 2x + 2 = \frac{1}{2}x \) \text{ from (9)}

\[ \rightarrow x = \frac{-4}{3} \]

Substituting in \( g \), we have

\[ \frac{16}{9} + 4y^2 = 24 \rightarrow y = \pm \frac{\sqrt{50}}{3} \]

\[ \therefore (x, y) = \left(\frac{-4}{3}, \frac{\sqrt{50}}{3}\right) \text{ or } \left(\frac{-4}{3}, \frac{-\sqrt{50}}{3}\right) \]

Now, to find the minimum and maximum temperature \( T \), substituting all points in \( T \)

\[ T(-1,0) = -1 \]

\[ T\left(\sqrt{24}, 0\right) = 24 + 2\sqrt{24} \approx 33.8 \]

\[ T\left(-\sqrt{24}, 0\right) = 24 - 2\sqrt{24} \approx 14.2 \]

\[ T\left(\frac{-4}{3}, \frac{\sqrt{50}}{3}\right) = \frac{14}{3} \approx 4.7 \]

\[ T\left(\frac{-4}{3}, \frac{-\sqrt{50}}{3}\right) = \frac{14}{3} \approx 4.7 \]

Note that the minimum temperature is \((-1)\) at the point \((-1,0)\) and the maximum temperature is \((33.8)\) at the point \((\sqrt{24}, 0)\).
Remark if there are two constraints intersecting, say $g(x, y, z) = 0$ and $h(x, y, z) = 0$, we introduce two Lagrange's multipliers $\lambda$ and $\mu$ and the relation will be

$$\nabla f(x, y, z) = \lambda \nabla g(x, y, z) + \mu \nabla h(x, y, z)$$

**Ex.26:** the plane $x + y + z = 12$ intersects with the cone $z = x^2 + y^2$ by an ellipse. Find the point on the intersection that is nearest to the origin.

Sol. $f(x, y, z) = x^2 + y^2 + z^2$

$g(x, y, z) = x + y + z - 12 = 0$

$h(x, y, z) = x^2 + y^2 - z = 0$

$$\nabla f(x, y, z) = \lambda \nabla g(x, y, z) + \mu \nabla h(x, y, z)$$

$< 2x, 2y, 2z > = \lambda < 1, 1, 1 > + \mu < 2x, 2y, -1 >$

$\therefore 2x = \lambda + 2\mu x \ldots (11)$

$2y = \lambda + 2\mu y \ldots (12)$

$2z = \lambda - \mu \ldots (13)$

From (11) and (12)

$$\lambda = 2x(1 - \mu) \quad \lambda = 2y(1 - \mu) \Rightarrow 2x(1 - \mu) = 2y(1 - \mu) \Rightarrow (2x - 2y)(1 - \mu) = 0$$
Then $1 - \mu = 0 \rightarrow \mu = 1 \rightarrow \lambda = 0$ from (11) & (12).

Substituting in (13) we have $z = \frac{-1}{2}$ ...(14)

Substituting (14) in $g$ and $h$, we have

$x + y - \frac{1}{2} - 12 = 0$

$x^2 + y^2 = -\frac{1}{2}$ (Contradiction)

Or $2x - 2y = 0 \rightarrow x = y$, in this case (Substituting in $h$ and $g$) we get

In $hx^2 + y^2 - z = 0 \rightarrow z = 2x^2$

In $g2x + 2x^2 - 12 = 0 \rightarrow x^2 + x - 6 = 0$

$(x + 3)(x - 2) = 0 \rightarrow x = -3$ or $x = 2$

$x = y \& z = 2x^2 \rightarrow (x, y, z) = (2,2,8)$ or $(-3,-3,18)$

When $(x, y, z) = (2,2,8) \rightarrow f(2,2,8) = 72$

When $(x, y, z) = (-3,-3,18) \rightarrow f(-3,-3,18) = 342$

Then $(2,2,8)$ is the nearest to the origin.

... Exercises ...

1)) Find the point on the curve $y = x^2 + 3$ that is nearest the origin, using the method of Lagrange multipliers.

2)) Find the minimum distance from the surface $x^2 + y^2 - z^2 = 1$ to the origin.

3)) Find the point on the surface $z = xy + 1$ nearest the origin.
4)) Find the maximum and minimum values of \( f(x, y, z) = x - 2y + 5z \) on the sphere \( x^2 + y^2 + z^2 = 30 \).

5)) Find the maximum value of \( f(x, y) = 49 - x^2 - y^2 \) on the line \( x + 3y = 10 \).

6)) The temperature at a point \((x, y)\) on a metal plate is \( T(x, y) = 4x^2 - 4xy + y^2 \). An ant on the plate walks around the circle of radius 5 centered at the origin what are the highest and lowest temperatures encountered by the ant?

7)) Factory produces three types of product \( x, y, z \), the factory’s profit (calculated in thousands of dollars) can be formulated in equation \( p(x, y, z) = 4x + 8y + 2z \), where the account is bounded by \( x^2 + 4y^2 + 2z^2 \leq 800 \), find highest profit for the factory.

8)) Find the greatest and smallest values that the function \( f(x, y) = xy \) takes on the ellipse \( \frac{x^2}{8} + \frac{y^2}{2} = 1 \).

9)) Find the point on the sphere \( x^2 + y^2 + z^2 = 25 \) where \( f(x, y, z) = x + 2y + 3z \) has its maximum and minimum values.

10)) Find three real numbers whose sum is 9 and the sum of whose squares is as small as possible.
