6. Discussion and Analysis of Table Results

1. This paper discussed a various number of jobs (n), starting from $n = 3:10$, $n = 11:19$, $n = 20:10:90$ and $n = 100:100:500$, with number of iterations (NI) which is suitable to specific n to solve the two problems (P) and (P_1).
2. The parameters of testing the efficiency of LSM (BA and PSO) and NN-BP are calculated, these parameters represented by, the exact efficient solutions of F and F_1 (are calculated using CEM for $n \leq 10$), the local search and NN-BP best efficient solutions (EP) and their averages, the AMAE, MAER the consuming time which calculated for (5) experiments, the CT and BT and their averages and lastly, the number of iterations which found the corresponding BS or EP.
3. For problem (P):
   - Table (*2)*: NN has exact results compared with CEM for $n = 3:10$.
   - Table (*3)*:NN has MAER, near 100% similar to HM results for $n = 11:19$.
   - Table (5): MBAB is near to NN by (75%) for $n = 20:10:90$.
   - Table (4): HM is better than NN, in 5 similar from 9 solutions, for $n = 20:10:100$.
   - Table (6): MBAB is near to NN by (100%) for $n = 100:100:500$.
   - NN is better than HM, for $n = 11:19$.
   - NN has little difference in time with MBAB for $n = 20:10:90$.
   - NN is the best from BA, PSO and MBAB for $n = 100:100:500$.
4. For problem (P_1):
   - Table (*7*): NN has exact results compared with CEM for $n = 3:10$.
   - Table (8): NN has AMAE=1.0, so its very closed to BAB for $n = 11:15$ (see figure (1)).
   - Table (9): NN has AMEA=3.8 so its very closed to HM (see figure (2)) for $n = 20:10:100$.
   - Table (10): PSO has mean of BS= 3259.2, BA has mean of BS= 3264.8, while NN has mean of BS= 3265.8, but they are very closed to each other for $n = 100:100:500$ (see figure (3)).

7. Conclusions

1. An NN applied to solve the problems (P) and (P_1), were found that the NN gave an effecient and optimal solutions for $n \leq 500$.
2. NN is best in consuming time than BA and PSO, for all n for all common tables.
3. Some local search methods can be used as learning algorithms (like PSO or genetic algorithm) for NN to solve MSP.
4. An interesting future research topic would involve experimentation with exact, local Search and neural network algorithms for the following problems.
   a. $1/r_j/(T_{max}, V_{max}, \sum V_j)$.
   b. $1//lex(V_{max}, T_{max}, \sum V_j)$.
   c. $1//lex(\sum V_j, T_{max}, V_{max})$.

Properties and Applications of Truncated Exponential Marshall Olkin Weibull Distribution

Properties and Applications of Truncated Exponential Marshall Olkin Weibull Distribution

Nadia Hashim Al-Noor and Hadi Hassan Hadi

Department of Mathematics, College of Science, Mustansiriyah University, Baghdad, Iraq

E-mail: nadialnoor@uomustansiriyah.edu.iq

Abstract. A new flexible compound distribution with four parameters called Truncated Exponential Marshall Olkin Weibull (TEMOW) is proposed as a sub-model of a new generator of continuous distributions named Truncated Exponential Marshall Olkin-G family. Reliability characteristics with several main statistical properties are presented. The maximum likelihood estimation method is adopted to estimate the unknown parameters. Furthermore, to assess the usefulness and flexibility, the TEMOW distribution applied upon simulation study besides real application with two real data set. The simulation results clearly shown the flexible performance of the maximum likelihood estimators for the parameters. Also, the real application results clearly shown that the proposed distribution has outstanding performance than other considered distributions for all information criteria.

1. Introduction

Over the last decades, various statistical distributions have been used to model data in a variety of areas. However, in some areas of use, there is a strong need to construct expanded versions of these distributions to adapt to particular real-life data. Several new generalized distributions have recently been developed and studied. Moreover, attempts continue to identify new families of probability distributions that expand well-known distribution families and at the same time providing greater flexibility in the practice of modeling results. One of the most important distributions is the Weibull distribution. It has been applied in various fields, especially to fit lifetime data. However, some of these applications are limited partly and this limitation undoubtedly inspired researchers to develop different generalizations and many modifications of this distribution in order to improve its flexibility. So, in this paper, based on the existing Weibull distribution, we introduce a new family of probability distributions arising from composing the work of Marshall and Olkin[1] with the work of Eugene et al. [2].

Marshall and Olkin [1] used tilting parameter α ($\alpha \geq 0$) to proposed an elastic family of probability distributions named Marshall Olkin-G (MO-G) with the following cumulative distribution function (cdf) and probability density function (pdf)

$$M(x)_{MO} = \frac{G(x)}{\alpha + \bar{\alpha}\, G(x)} \; ; \; \alpha \geq 0 \; , \bar{\alpha} = 1 - \alpha \tag{1}$$

$$m(x)_{MO} = \frac{\alpha\, g(x)}{\left(\alpha + \bar{\alpha}\, G(x)\right)^2} \tag{2}$$

where $G(x)$ and $g(x)$ are the cdf and pdf of any baseline distribution(see [3][4]).

Eugene et al. [2] introduced a new family built on the interval [0,1] beta distribution with the following cdf and pdf

$$F(x)_T = \frac{1}{\beta(a,b)} \int_0^{M(x)} z^{a-1} (1-z)^{b-1} \, dz \; ; \; 0 < a, b < \infty \tag{3}$$

$$f(x)_T = \frac{1}{\beta(a,b)} (M(x))^{a-1} (1-M(x))^{b-1} \, m(x) \tag{4}$$

where $\beta(a,b)$ is the Beta function, $M(x)$ and $m(x)$ are the cdf and pdf of any distribution.Then by taking $M(x)$ to be the cdf of the normal distribution, Eugene et al. defined the beta normal distribution and also derived some properties of this new distribution (see [2][5]).

Based on the two works above, our new family called truncated exponential Marshall Olkin – G has been built (for truncated distribution see [6]). The rest of this paper is structured as follows: In Section 2, the truncated exponential Marshall Olkin – G family is introduced with some general expressions. Then, in Section 3, attention is given to the truncated exponential Marshall Olkin Weibull as a particular member of this new family. In Sections 4, and 5 reliability measures and various properties of new distribution along with its entropies, and reliability stress strength model are introduced. In Section 6, the maximum likelihood estimators (MLEs) of the unknown parameters are presented. In Section 7, a simulation study is carried out to exhibit the performances of the MLEs, as well as, real applications are adopted to illustrate the behavior of the new distribution with some existing distributions. Finally, conclusions are addressed in Section 8.

2. Truncated exponential Marshall Olkin-G family

Considerthe cdf and pdf of the [0,1] truncated exponential (TE) distribution as

$$W(x)_{TE} = \frac{1 - e^{-\theta x}}{1 - e^{-\theta}} \; ; \; 0 < x < 1 \, , \theta > 0 \tag{5}$$

$$w(x)_{TE} = \frac{\theta e^{-\theta x}}{1 - e^{-\theta}} \tag{6}$$

Now,composing the two continuous cdfs,i.e. W and M,so that the cdf$F(x) = W\big(M(x)\big)$and pdf $f(x) = \frac{\partial}{\partial x} F(x)$ will be

$$F(x) = \int_0^{M(x)} \frac{\theta e^{-\theta u}}{1 - e^{-\theta}} \, du = \frac{1 - e^{-\theta M(x)}}{1 - e^{-\theta}} \tag{7}$$

$$f(x) = \frac{\theta m(x) e^{-\theta M(x)}}{1 - e^{-\theta}} \tag{8}$$

Substituting (1) and (2) in (7) and (8),a new family of probability distributions called Truncated Exponential Marshall Olkin-G (TEMO-G) can be proposed with the following cdf and pdf

$$F(x)_{TEMO-G} = \frac{1 - e^{-\theta \frac{G(x)}{\alpha + \bar{\alpha} \, G(x)}}}{1 - e^{-\theta}} \tag{9}$$

$$f(x)_{TEMO-G} = \frac{\theta \alpha g(x) e^{-\theta \frac{G(x)}{\alpha + \bar{\alpha} \, G(x)}}}{(1 - e^{-\theta})\big(\alpha + \bar{\alpha} \, G(x)\big)^2} \tag{10}$$

The formula of the pdf in (10)can be expansion by using the expressions $e^{-x} = \Sigma_{i=0}^{\infty} \frac{(-1)^i}{i!} x^i$ and $(1-x)^{-a} = \Sigma_{i=0}^{\infty} \frac{\Gamma(a+i)}{i! \, \Gamma(a)} x^i \, , |x| < 1, a > 0$ with performing some simple mathematical stepsas

$$f^E(x)_{TEMO-G} = \delta g(x) \big(G(x)\big)^{i+j} \tag{11}$$

where

$$\delta = \frac{1}{1 - e^{-\theta}} \Sigma_{i,j=0}^{\infty} \frac{(-1)^{i+j}}{i! \; j!} \frac{\Gamma(i+j+2)}{\Gamma(i+2)} \frac{\theta^{i+1} (\bar{\alpha})^j}{\alpha^{i+j+1}} \tag{12}$$

3- Truncated exponential Marshall Olkin Weibulldistribution

Let $G(x)$ and $g(x)$in (9), (10), and (11)be the cdf and pdf of the Weibull distribution [7] with two non-negative parametersλ and β,a new proposed distribution named Truncated Exponential Marshall Olkin Weibull($TEMOW$) distribution is attainedas a member of TEMO-G family with the cdf,pdf and expanded pdf respectively given by

$$F(x)_{TEMOW} = \frac{1 - e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}}{1 - e^{-\theta}} \tag{13}$$

$$f(x)_{TEMOW} = \frac{\theta\alpha\lambda\beta\, x^{\beta-1}\, e^{-\lambda x^{\beta}} e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}}{(1 - e^{-\theta})\left(\alpha + \bar{\alpha}\left(1 - e^{-\lambda x^{\beta}}\right)\right)^2} \tag{14}$$

and

$$f^{E}(x)_{TEMOW} = \delta\lambda\beta\, x^{\beta-1}\, e^{-\lambda x^{\beta}} \left(1 - e^{-\lambda x^{\beta}}\right)^{i+j} \tag{15}$$

with δas in (12).

The plots of some possible shapes of the cdf andpdf of the TEMOW distribution forspecific values of four parameters are presented in figures 1 and 2. Figure 1 clearly shows the characteristics of the cdf that are $0 \leq F(x)_{TEMOW} \leq 1$, strictly increasing, and continuous. Figure 2 shows some of the possible shapes of $TEMOW$pdf such as decreasing, right-skewed, symmetric,andsemi-symmetric. So, it is very flexible to model positive data.

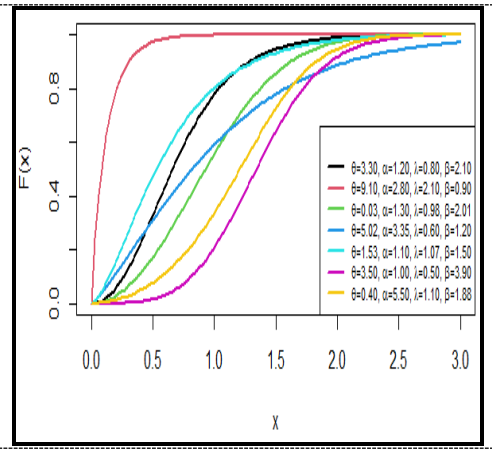

Figure 1. The plot of $TEMOW$ cdf for specific parameters values.

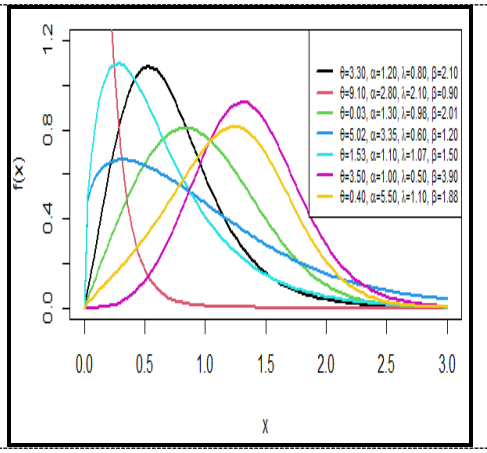

Figure 2. The plot of $TEMOW$ pdf for specific parameters values.

4- Reliability measures and properties of TEMOW distribution

The reliability measures (reliability, hazard, reverse hazard, and cumulative hazard functions) (see [8]) of the proposed TEMOW distribution easily can be found respectively as follows

$$R(x)_{TEMOW} = 1 - F(x)_{TEMOW} = 1 - \frac{1 - e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}}{1 - e^{-\theta}} \tag{16}$$

$$h(x)_{TEMOW} = \frac{f(x)_{TEMOW}}{R(x)_{TEMOW}} = \frac{\theta\alpha\lambda\beta\, x^{\beta-1}\, e^{-\lambda x^{\beta}} e^{-\theta\frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}}{\left(\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)\right)^{2}\left(e^{-\theta\frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}-e^{-\theta}\right)} \quad (17)$$

$$\tau(x)_{TEMOW} = \frac{f(x)_{TEMOW}}{F(x)_{TEMOW}} = \frac{\theta\alpha\lambda\beta\, x^{\beta-1}\, e^{-\lambda x^{\beta}} e^{-\theta\frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}}{\left(\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)\right)^{2}\left(1-e^{-\theta\frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}\right)} \quad (18)$$

$$H(x)_{TEMOW} = -\ln(R(x)_{TEMOW}) = -\ln\left(1-\frac{1-e^{-\theta\frac{1-e^{-\lambda x^{\beta}}}{\alpha+\bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}}{1-e^{-\theta}}\right) \quad (19)$$

The plots of some possible shapes of the reliability and hazard functions of the TEMOW distribution for specific values of four parameters are presented in figures 3 and 4. Figure 3 clearly shows the characteristics of the reliability that are $0 \le \mathrm{R(x)_{TEMOW}} \le 1$, strictly decreasing, and continuous. Figure 4 shows some of the possible shapes of TEMOWhazard function such as monotonically increasing, monotonically decreasing, bathtub, right-skewed, left-skewed, and semi-constant.

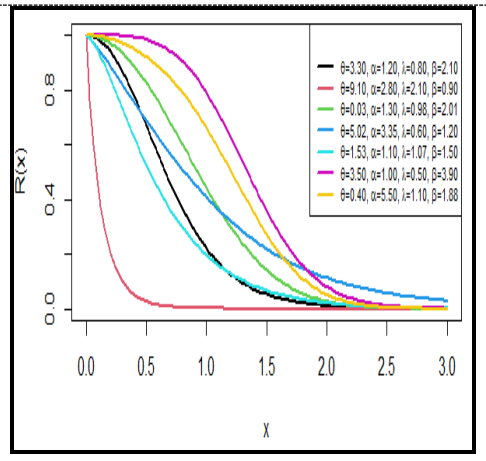

Figure 3. The plot of *TEMOW* reliability for specific parameters values.

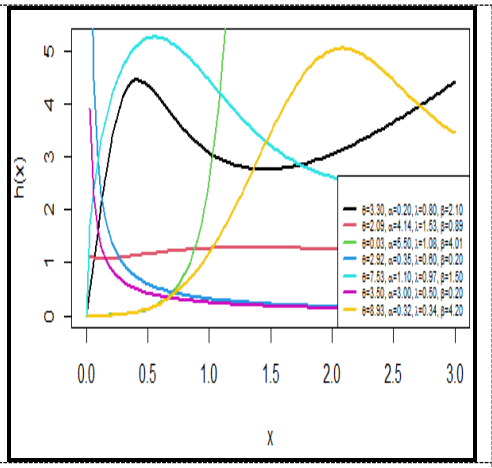

Figure 4. The plot of *TEMOW* hazard for specific parameters values.

Furthermore, themost essential statistical properties of TEMOW distribution can be found as follows: Therth moment can be foundregarding to (15)as follows

$$E(X^{r})_{TEMOW} = \int_{0}^{\infty} x^{r} f^{E}(x)_{TEMOW}\, dx = \delta \int_{0}^{\infty} x^{r}\lambda\beta\, x^{\beta-1}\, e^{-\lambda x^{\beta}}\left(1-e^{-\lambda x^{\beta}}\right)^{i+j} dx$$

Using the expression $(1-x)^{a} = \Sigma_{i=0}^{\infty}\frac{(-1)^{i}\,\Gamma(a+1)}{i!\,\Gamma(a-i+1)}x^{i}$, $|x|<1, a>0$,the $E(X^{r})_{TEMOW}$ will be

$$E(X^r)_{TEMOW} = \delta \int_0^{\infty} x^r \lambda\beta\, x^{\beta-1}\, e^{-\lambda x^{\beta}} \Sigma_{m=0}^{\infty} \frac{(-1)^m\, \Gamma(i+j+1)}{m!\ \Gamma(i+j-m+1)} e^{-\lambda m x^{\beta}}\, dx$$

$$= \delta\, \Sigma_{m=0}^{\infty} \frac{(-1)^m\, \Gamma(i+j+1)}{m!\ \Gamma(i+j-m+1)} \int_0^{\infty} x^r \lambda\beta\, x^{\beta-1} e^{-\lambda(m+1)x^{\beta}}\, dx$$

$$= \delta\, \Sigma_{m=0}^{\infty} \frac{(-1)^m\, \Gamma(i+j+1)}{m!\ \Gamma(i+j-m+1)} \frac{1}{m+1} \int_0^{\infty} x^r \lambda(m+1)\beta\, x^{\beta-1} e^{-\lambda(m+1)x^{\beta}}\, dx$$

But $\int_0^{\infty} x^r \lambda(m+1)\beta\, x^{\beta-1} e^{-\lambda(m+1)x^{\beta}}\, dx$represent the r^{th} moment of Weibull distribution with parameters$\lambda(m+1)$ and β, i.e. $\int_0^{\infty} x^r \lambda(m+1)\beta\, x^{\beta-1} e^{-\lambda(m+1)x^{\beta}}\, dx = \big(\lambda(m+1)\big)^{-\frac{r}{\beta}} \Gamma\left(\frac{r}{\beta}+1\right)$.
Thus the r^{th} moment of the $TEMOW$distribution is given by

$$E(X^r)_{TEMOW} = \delta\, \Sigma_{m=0}^{\infty} \frac{(-1)^m \Gamma(i+j+1)}{m!\ \Gamma(i+j-m+1)} \frac{1}{(m+1)^{\frac{r}{\beta}+1} \lambda^{\frac{r}{\beta}}} \Gamma\left(\frac{r}{\beta}+1\right) \quad (20)$$

The $TEMOW$characteristic function can be achievedfrom $\varphi_X(t)_{TEMOW} = \sum_{r=0}^{\infty} \frac{(it)^r}{r!} E(X^r)_{TEMOW}$ as

$$\varphi_X(t)_{TEMOW} = \delta \sum_{m,r=0}^{\infty} \frac{(-1)^m (it)^r\, \Gamma(i+j+1)}{m!\, r!\, \Gamma(i+j-m+1)} \frac{1}{(m+1)^{\frac{r}{\beta}+1} \lambda^{\frac{r}{\beta}}} \Gamma\left(\frac{r}{\beta}+1\right) \quad (21)$$

The $TEMOW$quantile function can be achieved through inverting the cdf in(13)as

$$x_{q-TEMOW} = \left[-\frac{1}{\lambda} \ln\left(1 + \frac{\alpha \ln\big(1-\big(1-e^{-\theta}\big)q\big)}{\theta + \bar{\alpha} \ln(1-(1-e^{-\theta})q)} \right) \right]^{\frac{1}{\beta}} \quad (22)$$

The median of TEMOW random variable can be gained from (22)by setting q = 0.5.Also, based on the quantile function with specific values, we can compute the skewness (γ_1) that defined by Galton [9], and kurtosis (γ_2) that defined by Moors [10], as

$$\gamma_1 = \frac{\mathrm{Q}(0.75) - 2\mathrm{Q}(0.5) + \mathrm{Q}(0.25)}{\mathrm{Q}(0.75) - \mathrm{Q}(0.25)}$$

$$\gamma_2 = \frac{\mathrm{Q}(0.875) - \mathrm{Q}(0.625) + \mathrm{Q}(0.375) - \mathrm{Q}(0.125)}{\mathrm{Q}(0.75) - \mathrm{Q}(0.25)}$$

where Q(.) = $x_{(.)-TEMOW}$ is computed from (22).
The $TEMOW$ random samplecan be simulated based on U that has a standard Uniform distribution as

$$x_{TEMOW} = \left[-\frac{1}{\lambda} ln\left(1 + \frac{\alpha\, ln\big(1-\big(1-e^{-\theta}\big)U\big)}{\theta + \bar{\alpha}\, ln(1-(1-e^{-\theta})U)} \right) \right]^{\frac{1}{\beta}} \quad (23)$$

5.Theentropies, reliability stress strengthandorder statistics of TEMOW distribution
Shannon entropy: Regarding to (14), theTEMOW Shannon entropy can be achievedas follows $SE_{TEMOW} = -\int_0^{\infty} \ln(f(x)_{TEMOW})\, f(x)_{TEMOW}\, dx$ with

$$\ln(f(x)_{TEMOW}) = \ln\left(\frac{\theta\alpha\lambda\beta}{1-e^{-\theta}}\right) + (\beta-1)\ln(x) - \lambda x^{\beta} - \theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha + \bar{\alpha}\big(1-e^{-\lambda x^{\beta}}\big)}$$
$$- 2\ln\left(\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)\right)$$

Then

$$SE_{TEMOW} = \ln\left(\frac{1-e^{-\theta}}{\theta\alpha\lambda\beta}\right) - (\beta-1)E(\ln(X)) + \lambda E\big(X^{\beta}\big) + \theta E\left(\frac{1-e^{-\lambda X^{\beta}}}{\alpha + \bar{\alpha}\big(1-e^{-\lambda X^{\beta}}\big)}\right)$$
$$+ 2E\left(\ln\left(\alpha + \bar{\alpha}\left(1-e^{-\lambda X^{\beta}}\right)\right)\right) \quad (24)$$

where $E\big(X^{\beta}\big)$ as in (20) with $r = \beta$, and

$$E(\ln(X)) = \int_0^\infty \ln(x)\, f^E(x)_{TEMOW}\, dx = \delta \int_0^\infty \ln(x)\, \lambda\beta\, x^{\beta-1}\, e^{-\lambda x^\beta} \left(1 - e^{-\lambda x^\beta}\right)^{i+j} dx$$

Since $\left(1 - e^{-\lambda x^\beta}\right)^{i+j} = \Sigma_{m=0}^\infty \frac{(-1)^m\, \Gamma(i+j+1)}{m!\, \Gamma(i+j-m+1)} e^{-\lambda m x^\beta}$, then

$$E(\ln(X)) = \delta \Sigma_{m=0}^\infty \frac{(-1)^m\, \Gamma(i+j+1)}{m!\ \Gamma(i+j-m+1)} \int_0^\infty \ln(x)\, \lambda\beta\, x^{\beta-1}\, e^{-\lambda(m+1)x^\beta} dx$$

Using the transformation $y = \lambda(m+1)x^\beta$ and then according to special formula of $\int_0^\infty \ln(y)\, e^{-y} dy = \psi(1)$(see [11]) where $\psi(.)$ represent the psi function, we get

$$E(\ln(X)) = \delta\, \Sigma_{m=0}^\infty \frac{(-1)^m\, \Gamma(i+j+1)}{\beta(m+1)!\ \Gamma(i+j-m+1)} \left[\psi(1) - \ln\big(\lambda(m+1)\big)\right] \quad (25)$$

and

$$E\left(\frac{1 - e^{-\lambda X^\beta}}{\alpha + \bar{\alpha}\big(1 - e^{-\lambda X^\beta}\big)}\right) = \int_0^\infty \frac{1 - e^{-\lambda X^\beta}}{\alpha + \bar{\alpha}\big(1 - e^{-\lambda X^\beta}\big)}\, f(x)_{TEMOW}\, dx$$

Using the expressions$(1-x)^{-a}$, $(1-x)^a$, and e^{-x}that mentioned previously, we obtain

$$E\left(\frac{1 - e^{-\lambda X^\beta}}{\alpha + \bar{\alpha}\big(1 - e^{-\lambda X^\beta}\big)}\right) = \sum_{m,l,t=0}^\infty \frac{(-1)^{m+l+t}\Gamma(m+2)}{l!\, t!\, \Gamma(m-l+2)} \frac{(\bar{\alpha})^m}{\alpha^{m+1}} (\lambda l)^t\, E\big(X^{t\beta}\big) \quad (26)$$

and

$$E\left(\ln\left(\alpha + \bar{\alpha}\left(1 - e^{-\lambda X^\beta}\right)\right)\right) = \int_0^\infty \ln\left(\alpha + \bar{\alpha}\left(1 - e^{-\lambda X^\beta}\right)\right) f(x)_{TEMOW}\, dx$$

Using the expressions $ln(1-x) = -\Sigma_{i=0}^\infty \frac{x^{i+1}}{i+1}$; $|x| < 1$, $(1-x)^a$, and e^{-x} we obtain

$$E\left(\ln\left(\alpha + \bar{\alpha}\left(1 - e^{-\lambda X^\beta}\right)\right)\right) = \ln(\alpha) + \sum_{m,l,t=0}^\infty \frac{(-1)^{m+l+t+2}\, \Gamma(m+2)}{(m+1)l!\, t!\ \Gamma(m-l+2)} \left(\frac{\bar{\alpha}}{\alpha}\right)^{m+1} (\lambda l)^t E\big(X^{t\beta}\big) \quad (27)$$

where $E\big(X^{t\beta}\big)$ as in (20) with $r = t\beta$.

Relative entropy:The relative entropyof the $TEMOW$ distribution can be obtained by taking the mathematical expectation of $\ln\left(\frac{f(x)_{TEMOW}}{f_1(x)_{TEMOW}}\right)$where $f(x)_{TEMOW}$ is the pdf with parameters $(\theta, \alpha, \lambda, \beta)$as in (14) and $f_1(x)_{TEMOW}$ is the pdf with parameters $(\theta_1, \alpha_1, \lambda_1, \beta_1)$ as

$$\ln \frac{f(x)_{TEMOW}}{f_1(x)_{TEMOW}} = \ln\left(\frac{\theta\alpha\lambda\beta\big(1 - e^{-\theta_1}\big)}{\theta_1\alpha_1\lambda_1\beta_1(1 - e^{-\theta})}\right) + (\beta - \beta_1)\ln(x) - \lambda x^\beta + \lambda_1 x^{\beta_1} - \theta \frac{1 - e^{-\lambda x^\beta}}{\alpha + \bar{\alpha}\big(1 - e^{-\lambda x^\beta}\big)}$$
$$+ \theta_1 \frac{1 - e^{-\lambda_1 x^{\beta_1}}}{\alpha_1 + \overline{\alpha_1}\big(1 - e^{-\lambda_1 x^{\beta_1}}\big)} - 2\ln\left(\alpha + \bar{\alpha}\left(1 - e^{-\lambda x^\beta}\right)\right)$$
$$+ 2\ln\left(\alpha_1 + \overline{\alpha_1}\left(1 - e^{-\lambda_1 x^{\beta_1}}\right)\right)$$

Thus, the $TEMOW$ relative entropy is given by

$$RE_{TEMOW} = E\left(\ln \frac{f(x)_{TEMOW}}{f_1(x)_{TEMOW}}\right) = \ln\left(\frac{\theta\alpha\lambda\beta\big(1 - e^{-\theta_1}\big)}{\theta_1\alpha_1\lambda_1\beta_1(1 - e^{-\theta})}\right) + (\beta - \beta_1)E(\ln(X))$$
$$-\lambda E\big(X^\beta\big) + \lambda_1 E\big(X^{\beta_1}\big) - \theta E\left(\frac{1 - e^{-\lambda X^\beta}}{\alpha + \bar{\alpha}\big(1 - e^{-\lambda X^\beta}\big)}\right) + \theta_1 E\left(\frac{1 - e^{-\lambda_1 X^{\beta_1}}}{\alpha_1 + \overline{\alpha_1}\big(1 - e^{-\lambda_1 X^{\beta_1}}\big)}\right)$$
$$-2E\left(\ln\left(\alpha + \bar{\alpha}\left(1 - e^{-\lambda X^\beta}\right)\right)\right) + 2E\left(\ln\left(\alpha_1 + \overline{\alpha_1}\left(1 - e^{-\lambda_1 X^{\beta_1}}\right)\right)\right) \quad (28)$$

where$E\big(X^\beta\big)$and $E\big(X^{\beta_1}\big)$as in (20)with $r = \beta$andβ_1. The other mathematical expectations as in (25), (26)and (27)with indicated parameters.

Reliability stress strength model:Consider $f_X(x)$ the pdf of the strength random variable(X) as in (14)and $F_Y(x)$ the cdf of the stress random variable(Y)as in (13)with parameters $(\theta_1, \alpha_1, \lambda_1, \beta_1)$. The

reliability stress strengthmodel associated withtwo independent$TEMOW$random variables can be achieved as follows

$$SS_{TEMOW} = P(Y < X) = \int_0^{\infty} f_X(x)\, F_Y(x)\, dx = \frac{1}{1-e^{-\theta_1}} \int_0^{\infty} \left(1 - e^{-\theta_1 \frac{1-e^{-\lambda_1 x^{\beta_1}}}{\alpha_1 + \overline{\alpha_1}\left(1-e^{-\lambda_1 x^{\beta_1}}\right)}}\right) f_X(x) dx$$

Afterusing the expansion formulas of e^{-x}, $(1-x)^{-a}$, and $(1-x)^{a}$along with some simplification steps we get

$$SS_{TEMOW} = \frac{1}{1-e^{-\theta_1}} \int_0^{\infty} \left[1 - \sum_{i,j,l,t=0}^{\infty} \frac{(-1)^{i+j+l+t}}{i!\, j!\, l!\, t!} \frac{\Gamma(i+j)\Gamma(i+j+1)\theta_1^i}{\Gamma(i)\Gamma(i+j-l+1)} \frac{(\overline{\alpha_1})^j}{{\alpha_1}^{i+j}} (\lambda_1 l)^t x^{t\beta_1}\right] f_X(x) dx$$

Then

$$SS_{TEMOW} = \frac{1}{1-e^{-\theta_1}} \left[1 - \sum_{i,j,l,t=0}^{\infty} \frac{(-1)^{i+j+l+t}}{i!\, j!\, l!\, t!} \frac{\Gamma(i+j)\Gamma(i+j+1)\theta_1^i}{\Gamma(i)\Gamma(i+j-l+1)} \frac{(\overline{\alpha_1})^j}{{\alpha_1}^{i+j}} (\lambda_1 l)^t E\left(X^{t\beta_1}\right)\right] \quad (29)$$

where $E\left(X^{t\beta_1}\right)$as in (20) with $r = t\beta_1$.

Order statistics: Let $x_{1:n}, x_{2:n}, \dots, x_{n:n}$ be the corresponding order statistics of a random sample $x_1, x_2, \dots, x_n$of size n taken independently from $TEMOW$ distribution. The pdf and the joint pdf of order statistics can be found based on (13) and (14)via the following standard formulas (see [11])

$$f_{k:n}(x) = \frac{n!}{(k-1)!\,(n-k)!} \left(F(x)\right)^{k-1} \left(1-F(x)\right)^{n-k} f(x) \;\; ; \; 0 \le x_{k:n} < \infty, k \le n$$

$$f_{j,k:n}(x,y) = \frac{n!}{(j-1)!\,(k-j-1)!\,(n-k)!} \left(F(x)\right)^{j-1} \left(F(y)-F(x)\right)^{k-j-1} \left(1-F(y)\right)^{n-k} f(x)\, f(y); \; 1 \le j \le k\,, 0 \le x \le y < \infty$$

Asfollows

$$f_{k:n}(x) = \frac{n!}{(k-1)!\,(n-k)!} \left(1 - e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}\right)^{k-1} \left(e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}} - e^{-\theta}\right)^{n-k}$$

$$\frac{\theta\alpha\lambda\beta\, x^{\beta-1}\, e^{-\lambda x^{\beta}} e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}}{(1-e^{-\theta})^n \left(\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)\right)^2}; \; 0 \le x_{k:n} < \infty, k \le n \quad (30)$$

$$f_{j,k:n}(x,y) = \frac{n!}{(j-1)!\,(k-j-1)!\,(n-k)!} \left(1 - e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}}\right)^{j-1} \left(e^{-\theta \frac{1-e^{-\lambda x^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)}} - e^{-\theta \frac{1-e^{-\lambda y^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda y^{\beta}}\right)}}\right)^{k-j-1} \left(e^{-\theta \frac{1-e^{-\lambda y^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda y^{\beta}}\right)}} - e^{-\theta}\right)^{n-k} \quad (31)$$

$$\frac{\theta^2\alpha^2\lambda^2\beta^2 x^{\beta-1} y^{\beta-1}\, e^{-\lambda\left(x^{\beta}+y^{\beta}\right)} e^{-\theta\left(\frac{1-e^{-\lambda x^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)} + \frac{1-e^{-\lambda y^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda y^{\beta}}\right)}\right)}}{(1-e^{-\theta})^n \left(\alpha + \bar{\alpha}\left(1-e^{-\lambda x^{\beta}}\right)\right)^2 \left(\alpha + \bar{\alpha}\left(1-e^{-\lambda y^{\beta}}\right)\right)^2}; \; 1 \le j \le k\,, 0 \le x \le y < \infty$$

6.Maximum likelihoodestimators of TEMOW parameters

Consider$(x_1, x_2, \dots, x_n)$a complete random sample of size nfollow TEMOWdistribution with the vector of parameters$\Delta = (\theta, \alpha, \lambda, \beta)^T$. Thenatural logarithm likelihood function based on (14)is

$$\ell(\Delta|\underline{x}) = n \ln\left(\frac{\theta\alpha\lambda\beta}{1-e^{-\theta}}\right) + (\beta-1)\Sigma_{i=1}^{n} \ln(x_i) - \lambda\Sigma_{i=1}^{n} x_i^{\beta} - \theta\Sigma_{i=1}^{n} \frac{1-e^{-\lambda x_i^{\beta}}}{\alpha + \bar{\alpha}\left(1-e^{-\lambda x_i^{\beta}}\right)}$$

$$-2\Sigma_{i=1}^{n} \ln\left(\alpha + \bar{\alpha}\left(1-e^{-\lambda x_i^{\beta}}\right)\right) \quad (32)$$

The maximum likelihood estimators of four parameters can be attained either directly by using the package (AdequecyModel) in R software or bysolving the nonlinear fourlikelihood equations$\frac{\partial \ell(\Delta|\underline{x})}{\partial \Delta} = \left(\frac{\partial \ell(\Delta|\underline{x})}{\partial \theta}, \frac{\partial \ell(\Delta|\underline{x})}{\partial \alpha}, \frac{\partial \ell(\Delta|\underline{x})}{\partial \lambda}, \frac{\partial \ell(\Delta|\underline{x})}{\partial \beta}\right)^T = 0$ throughcomputational iterative techniques.

In AdequecyModel package, there exists various maximization algorithms such as Newton-Raphson (NR), Broyden-Fletcher-Goldfarb-Shanno (BFGS), Berndt-Hall-Hall-Hausman (BHHH), Limited-Memory quasi-Newton code for Bound-constrained optimization (L-BFGS-B), Nelder-Mead (NM), and Simulated-Annealing (SANN). Here, the MLEs are computed directly by using the package (AdequecyModel) in R software with BFGS method.

7.Simulation and real application

In this section, numerical illustrations (simulation and real application) are presented to exhibit the abilities of the proposed distribution.

7.1. Simulation process

The first step of the simulation process is to generate i.i.d. random samples (1000 times) follow $TEMOW$ distribution each with size $n = 25,50,100,200$ and 300 where the true or initial values of parameters are chosen to be as in table 1 (also see figure 2). Then, for each parameter, calculate the Bias and root mean squared error (RMSE) as

$Bias(\hat{\eta}) = \frac{1}{1000}\sum_{i=1}^{1000}(\hat{\eta}_i - \eta)$ and

$RMSE(\hat{\eta}) = \sqrt{\frac{1}{1000}\sum_{i=1}^{1000}(\hat{\eta}_i - \eta)^2}$ where η can be $\theta, \alpha, \lambda,$ or β .

It clearly appears from the simulation results (table1) that RMSE values decrease as the sample size increases.

Table 1. The Bias and RMSE of the $TEMOW$ parameters estimation using MLE**.**

7.2.Real Application

In this subsection, we include applications for two real data sets (right-skewed and semi-symmetric)to exhibit the abilities andflexibility of the TEMOW distribution.

The first real data (Data-1) collection reflects the body fat percentage of 202 Australian athletes [12].

"19.75, 21.30, 19.88, 23.66, 17.64, 15.58, 19.99, 22.43, 17.95, 15.07, 28.83, 18.08, 23.30, 17.71, 18.77, 19.83, 25.16, 18.04, 21.79, 22.25, 16.25, 16.38, 19.35, 19.20, 17.89, 12.20, 23.70, 24.69, 16.58, 21.47, 20.12, 17.51, 23.70, 22.39, 20.43, 11.29, 25.26, 19.39 19.63 23.11 16.86 21.32 26.57 17.93 24.97 22.62 15.01, 18.14, 26.78, 17.22, 26.50, 23.01, 30.10, 13.93, 26.65, 35.52, 15.59, 19.61, 14.52, 11.47, 17.71, 18.48, 11.22, 13.61, 12.78, 11.85, 13.35, 11.77, 11.07, 21.30, 20.10, 24.88, 19.26, 19.51, 23.01, 8.07, 11.05, 12.39, 15.95, 9.91, 16.20, 9.02, 14.26, 10.48, 11.64, 12.16, 10.53, 10.15, 10.74, 20.86, 19.64, 17.07, 15.31, 11.07, 12.92, 8.45, 10.16, 12.55, 9.10, 13.46, 8.47, 7.68, 6.16, 8.56, 6.86, 9.40, 9.17, 8.54, 9.20, 11.72, 8.44, 7.19, 6.46, 9.00, 12.61, 9.03, 6.96, 10.05, 9.56, 9.36, 10.81, 8.61, 9.53, 7.42, 9.79, 8.97, 7.49, 11.95, 7.35, 7.16, 8.77, 9.56, 14.53, 8.51, 10.64, 7.06, 8.87, 7.88, 9.20, 7.19, 6.06, 5.63, 6.59, 9.50, 13.97, 11.66, 6.43, 6.99, 6.00, 6.56, 6.03, 6.33, 6.82, 6.20, 5.93, 5.80, 6.56, 6.76, 7.22, 8.51, 7.72, 19.94, 13.91, 6.10, 7.52, 9.56, 6.06, 7.35, 6.00, 6.92, 6.33, 5.90, 8.84, 8.94, 6.53, 9.40, 8.18, 17.41, 18.08, 9.86, 7.29, 18.72, 10.12, 19.17, 17.24, 9.89, 13.06, 8.84, 8.87, 14.69, 8.64, 14.98, 7.82, 8.97, 11.63, 13.49, 10.25, 11.79, 10.05, 8.51, 11.50, 6.26".

The second real data (Data-2)collection reflects the strengths of 1.5 cm glass fibers of 63 observations [13].

"0.55, 0.74, 0.77, 0.81, 0.84, 1.24, 0.93, 1.04, 1.11, 1.13, 1.30, 1.25, 1.27, 1.28,1.29, 1.48, 1.36, 1.39, 1.42, 1.48, 1.51, 1.49, 1.49, 1.50, 1.50,1.55, 1.52, 1.53, 1.54, 1.55, 1.61, 1.58,1.59, 1.60, 1.61, 1.63,1.61, 1.61, 1.62, 1.62, 1.67, 1.64, 1.66, 1.66, 1.66, 1.70, 1.68,1.68, 1.69, 1.70, 1.78, 1.73, 1.76, 1.76, 1.77, 1.89, 1.81, 1.82,1.84, 1.84, 2.00, 2.01, 2.24".

The fitting of TEMOW distribution is compared with the Beta Weibull (BW), Kumaraswamy Weibull (KuW), Exponentiated Generalized Weibull (EGW), Weibull Weibull (WW), Gompertz Weibull (GoW), and Weibull (W) distributions (see [14]-[18] for more details). The software R was used to calculate their negative log-likelihood (-LL), Consistent Akaike Information Criteria (CAIC), Akaike Information Criteria (AIC), Bayesian Information Criteria (BIC), Hanan and Quinn Information Criteria (HQIC), besides MLEs of the parameters.

The findings areshown in tables2 - 5.In addition to the plots of empirical cdfs, the histogram plot and the estimated densities are shown in figures 5 - 8. Based on the results, TEMOW has the lowest values of information criteria, makingit the most fitting to represent two data sets compared to other distributions. In addition, this best fitting can be seen via the plots.

8. Conclusions

In this paper, a newly generated family of continuous distributions with Marshall Olkin is introduced. Then a truncated distribution as a sub-model with four parameters called Truncated Exponential Marshall Olkin Weibull is proposed. Reliability analysis with several main statistical properties such as moments, characteristic function, quantile function, median, skewness, kurtosis, simulated data, Shannon entropy, relative entropy, reliability stress-strength model, and order statistics are presented. Furthermore, the maximum likelihood estimation method is used to estimate the unknown four parameters. To assess the usefulness and flexibility, the TEMOW distribution applied upon simulation study besides real application by the implementation of two real data sets (right-skewedand semi-symmetric) with different information criteria. The simulation results clearly shown the flexible and consistent performance of the maximum likelihood estimators for the parameters. Also, the real application results clearly shown that the proposed distribution has outstanding performance than other considered distributions for all information criteria. This flexibility allows using the TEMOW distribution in various application areas.

New Procedure for Selecting Raise Vector in Raising Regression

New Procedure for Selecting Raise Vector in Raising Regression

Abstract. One of the most important things in raise regression is selecting the raise factor λ. A new procedure for selecting the raised vector have been prepared with new technique for choosing the raising factor λ. Three different criterion have been used to study of this procedure, namely, scalar mean square error (MSE), determination coefficients R^2, and the variance inflation factor (VIF). Also, some examples have been given to illustrate our finding. Where the best MSE, acceptable R^2, VIF and reduce simultaneously the multicollinearity among vectors are the main results of this procedure by giving better estimate for raise factor λ which may apply in different fields that suffered from the problem of multicollinearity.

1. Introduction

Recently, [2] and [3] present and develop a new technique of raising regression depending on geometrical aspect, the idea behind is very simple to avoid the problem of multicollinearity in the linear regression model:

$$\boldsymbol{Y} = \boldsymbol{X\beta} + \boldsymbol{\epsilon}, \tag{1}$$

where Y is an $n \times 1$ vector of observations on the response variable, X is an $n \times p$ known design matrix of rank p, β is a $p \times 1$ vector of unknown regression coefficients and ϵ is an $n \times 1$ vector of the error terms with $E(\epsilon) = 0$ and $\mathrm{Cov}(\epsilon) = \sigma^2 I_n$.

Later, research teams - Garcia et al.- were published many research papers related to the raising regression relate to the raising vector λ [3] and developed the technique [9]

The multicollinearity problem ensure that the estimate of the regression coefficients have large variance and unstable with wrong sign if we use the ordinary least squares estimator (OLS) that given as follows:

$$\widehat{\boldsymbol{\beta}}_{\boldsymbol{OLS}} = (\boldsymbol{X'X})^{-1}\boldsymbol{X'Y} \tag{2}$$

In this case, the matrix X′X becomes almost singular and the estimator will distorts data. To dominate this problem many methods of regression were presented. One of the most efficient technique was the ordinary Ridge Regression (ORR) estimator suggested by Hoerl [6] given as:

$$\widehat{\boldsymbol{\beta}}_{\boldsymbol{k}} = (\boldsymbol{X'X} + \boldsymbol{kI_p})^{-1}\boldsymbol{X'Y} \tag{3}$$

Second estimation method presented to avoid multicollinearity is the selection of variables which delete one of the correlated vectors which may has important information, for this reason the raise regression method has be found.

The raise regression was developed by Salmeron et. al. (Salmeron et. al. 2017) where they used residuals of the model (1). Raise regression treat with data space but without deleting data this method

geometrically raises the correlated vector according to number of correlated vector x_j – namely, chose the vector with more collinearity and apply this for all vectors. In following regression:

$$\tilde{x}_j = x_j + \lambda_j e_j \quad (4)$$

For some vector x_j ,raise parameter λ_j is chosen by user [8] or may calculated to get best value of λ_j [2] and e_j is the residual vector. Then replace x_j by $\tilde{x}_j$ in the original model for all $j = 1, \dots, p$ which lead to replace all of vectors in the model with new $\tilde{x}_j$.

In this paper, a new procedure for selecting the raised vector will be prepared with new technique for choosing the raising parameter λ. We will use three different criterion to check the performance of raise regression technique for selecting the raised vector, namely, scalar mean square error (MSE), determination coefficients R^2, and the variance inflator factor (VIF)

The paper is organized as follows, in Section 2, the methodology is presented. In Section 3 some examples have been given to illustrate our finding. Finally, some conclusion remarks are given is Section 4.

2. Methodology

The raise estimator preserves the determination coefficient value R^2, independently raising parameter, λ [9]. Which is a different point with ridge regression. R^2 is also determined for seeking of comparison of different values of λ. R^2 is determined in the ordinary linear regression as following [2]:

R^2 is computed as:

$$R^2 = \frac{SSR}{SST} \text{ and } \tilde{R}^2 = \frac{\widetilde{SSR}}{\widetilde{SST}} \text{ , where } SST = \sum_i (Y_i - \bar{Y})^2 = \widetilde{SST} \text{ , } SSR = \sum_i e_{i0}^2 = \|e_0\|^2,$$
$$\bar{\boldsymbol{Y}} = (\bar{\boldsymbol{Y}}, \bar{\boldsymbol{Y}}, \dots, \bar{\boldsymbol{Y}}) = \bar{\boldsymbol{Y}}.\mathbf{1}' \text{ and } \|Y - \bar{Y}\|^2 = \left\|\hat{Y} - \bar{Y}\right\|^2 + \|e_0\|^2 \quad (5)$$

Therefore $SST = SSR + SSE$ and R2 may expressed as following:

$$R^2 = \frac{SSE}{SST} = \frac{\|\hat{Y} - \bar{Y}\|^2}{\|Y - \bar{Y}\|^2} \quad (6)$$

While the variance inflation factor VIF is defined as:

$$VIF = \frac{1}{1 - R^2} \quad (7)$$

The technique used in this research paper depends on selecting specific vector that has higher value correlation and then use different values of λ's for the selected vector to be raised. This λ is selected for minimum value of MSE.

The data assumed to be centered and standardized and written as $X = (x_1, x_2, \dots, x_p)$ of $(n \times p)$ matrix such that $\left\|x_j\right\|^2$ for $j = 1, .., p$. In matrix form $A = (a_1, a_2, \dots, a_p)$, the columns span (Span(A)) which is the subspace generated by the columns vectors $[a_1, a_2, \dots, a_p]$ while the subspace $A_{[j]}$is the matrix A deleting the vector a_j and $\text{Span}(A_{[j]})$ is the subspace generating by $A_{[j]}$ for the linear model (1) it is important to study the multicollinearity among vectors of X, deleting of the vector x_j is temporary which replaced by the new vector $\tilde{x}_j$ in order to reduce the mean square error MSE. Figure (1)

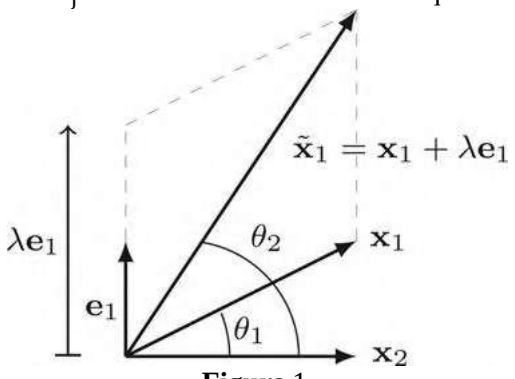

Figure 1.

2.1 Procedure of raising regression

Unlike the procedure of (Ramirez et al.2015), which raise all of the vectors x_js by $\tilde{x}_j$s for $j = 1, .., p$ we do raising for the high correlation vector in the following sequence:

Step 1. Chose the vector x_j with high correlation coefficient to begin raising $x_j \rightarrow \tilde{x}_j$ such that:

$$\tilde{\boldsymbol{x}}_{\boldsymbol{j}} = \boldsymbol{x}_{\boldsymbol{j}} + \lambda_j \boldsymbol{e}_{\boldsymbol{j}}$$

where e_j represents the orthogonal vector on $\mathrm{Span}(X_{[j]})$ ($e_j \perp \mathrm{Span}(X_{[j]})$), and λ_j is an arbitrary positive constant chosen from some interval of positive real numbers ensure the minimum MSE.

Step 2. Check the result and chose the next vector to be raise in the same manner with the new linear model:

$$\boldsymbol{Y} = \tilde{\boldsymbol{X}}\tilde{\boldsymbol{\beta}} + \boldsymbol{\epsilon}\,, \tag{8}$$

where $\tilde{X} = [x_1, x_2, \dots, x_{j-1}, \tilde{x}_j, x_{j+1}, \dots, x_p]$ and raising for new vector, and so on.

Step 3**.** Stopping criterion: when the improving is decay, the procedure stops and preserves the last result for $\tilde{\boldsymbol{X}}$ and $\boldsymbol{\beta}$.

Jensen and Ramirez [7] show that there is a relationship between the VIF, and the angle between x_j and $\mathrm{Span}(X_{[j]})$. The process of raising the vector between x_j and $\mathrm{Span}(X_{[j]})$ aims to increase the amount of the angle between them. Therefore, applying raising to all vectors may lead to undesirable results. λ_j should be chosen with caution to obtain the best result in terms of the MSE.

The suggestion here is to choose the best value of the parameter λ_j for each vector to avoid this issue. Suppose that x_j and x_k has a high correlation between them and we raise x_j first and then x_k secondly, but we may get high correlation between them again.

3. Illustrated Examples

In this section two examples will present to illustrate the new procedure.

3-1 Example 1

To illustrate our procedure in this last section we consider a dataset which was discussed in [4]. Data found in economics are often multicollinear. Which contains "Total National Research and Development Expenditures—as a Percent of Gross National Product by Country: 1972–1986. It represents the relationship between the dependent variable Y the percentage spent by the United States and the four other independent variables X1, X2, X3, and X4. The variable X1 represents the percent spent by France, X2 that spent by West Germany, X3 that spent by Japan, and X4 that spent by the former Soviet Union."

In (Akdeniz and Erol 2003), the following example is suggested in order to illustrate the measure of the multicollinearity. By applying procedure in step 1 to step 3, we get the following results that listed in table 1.

The correlation matrix of the original matrix is calculated as:

1.0000	0.8877	0.9248	0.3090
0.8877	1.0000	0.9621	0.1573
0.9248	0.9621	1.0000	0.3276
0.3090	0.1573	0.3276	1.0000

Here we choose the vector number 3 for its high value of correlation (0.9621). While in the second iteration the vector number 2 is selected for high value of correlation in the following correlation matrix (0.9426):

1.0000	0.8877	0.9060	0.3090
0.8877	1.0000	0.9426	0.1573
0.9060	0.9426	1.0000	0.3209
0.3090	0.1573	0.3209	1.0000

After second iteration, we get the following correlation matrix

1.0000	0.8017	0.9060	0.3090
0.8017	1.0000	0.8513	0.1421

0.9060 0.8513 1.0000 0.3209
0.3090 0.1421 0.3209 1.0000

In the third iteration, we chose the first vector for maximum correlation (0.9060). For minimum value of MSE we get the following correlation matrix:

1.0000 0.5294 0.5982 0.2040
0.5294 1.0000 0.8513 0.1421
0.5982 0.8513 1.0000 0.3209
0.2040 0.1421 0.3209 1.0000

According to the procedure, we have to stop where there is no improving of MSE and we get good correlation values.

Note that the relation between raising factor and the mean square error for each iteration is given in figure 2

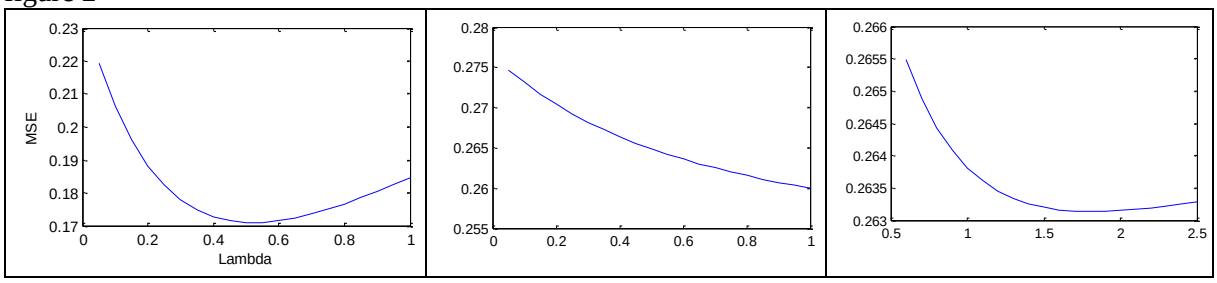

Figure 2. lambda verses MSE for three iterations

3-2 -Example 2

We now consider a dataset on Portland cement due to Hald [5] which widely analyses in the literature. These data are experimental investigation related to Portland cements of varied composition and the dependence of this heat on the percentages of four compounds. In this example, the dependent variable Y is defined as heat evolved in calories per gram of cement. The independent variables are amounts of

the following compounds: tricalcium aluminate (X1), tricalcium silicate (X2), tetracelcium alumino femrrite (X3), and dicalcium silicate (X4).

By applying procedure in step 1 to step 3, we get the following results that listed in Table 2 below. The Correlation matrix of the original matrix is calculated as:

1.0000	0.2286	-0.8241	-0.2454
0.2286	1.0000	-0.1392	-0.9730
-0.8241	-0.1392	1.0000	0.0295
-0.2454	-0.9730	0.0295	1.0000

Hear we chose the vector number 2 for its high value of correlation with -0.9730
While in the second iteration the vector number 4 is selected for high value of correlation in the following correlation matrix:

1.0000	0.2256	-0.8241	-0.2454
0.2256	1.0000	-0.1374	-0.9601
-0.8241	-0.1374	1.0000	0.0295
-0.2454	-0.9601	0.0295	1.0000

After second iteration, we get the following correlation matrix

1.0000	0.2256	-0.8241	-0.2428
0.2256	1.0000	-0.1374	-0.9497
-0.8241	-0.1374	1.0000	0.0292
-0.2428	-0.9497	0.0292	1.0000

In the third iteration, we chose the first vector.

For minimum value of MSE we get the following correlation matrix:

1.0000	0.2256	-0.6792	-0.2428
0.2256	1.0000	-0.1132	-0.9497
-0.6792	-0.1132	1.0000	0.0241
-0.2428	-0.9497	0.0241	1.0000

According the procedure, there is no improving of MSE and we get good correlation values.

Again, note that the relation between raising factor and the mean square error for each iteration is given below:

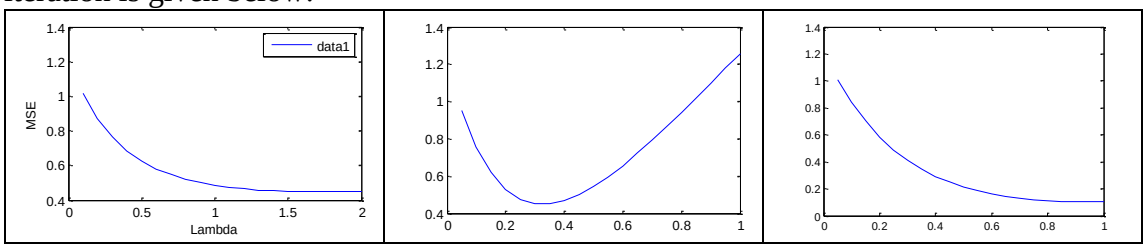

Figure 3. Lambda vesrse MSE for three iterations

4. Conclusion

One of the most important things in raise regression is selecting the raise factor λ , in this paper we produced a new procedure to select this factor among several values which guarantee best MSE and acceptable R^2 and VIF and reduce simultaneously the multicollinearity among vectors. This procedure give better estimate for raise factor λ which may applied in different fields that suffered from the problem of multicollinearity

Abstract. A space X is named a $\pi p-$ normal if for each closed set F and each $\pi-$ closed set F' in X with $F \cap F' = \emptyset$, there are $p-$ open sets U and V of X with $U \cap V = \emptyset$ whereas $F \subseteq U$ and $F' \subseteq V$. Our work studies and discusses a new kind of normality in generalized topological spaces. We define $\vartheta\pi p-$ normal, $\vartheta-$mildly normal, $\vartheta-$almost normal, ϑp-normal, $\vartheta-$mildly p-normal, $\vartheta-$almost p-normal and $\vartheta\pi$-normal space, and we discuss some of their properties.

1. Introduction and Preliminaries

In our paper a topological space will be denoted by X and the closure and the interior of F in X by cl(F) and int(F) respectively. The concept of $\pi p-$normal topological Spaces was introduced and considered by Sadeq (2012) [1].

We recall some concepts and notations defined previously by another authors. A subset F of a space X is said to be pre-open (briefly p-open) (resp. semi-open, α-open) if $F \subseteq \text{int}(\text{cl}(F))$(resp. $F \subseteq \text{cl}(\text{int}(F))$, $F \subseteq \text{int}\left(\text{cl}(\text{int}(F))\right)$)[2]. The complement of a p-open (resp. semi-open , α-open) set is called p- closed [3](resp. semi-closed[2], α-closed[4]). The following two definitions are taken from[2], preclosure of F is $\text{pcl}(F) = \bigcap\{F' : F' \text{ is a preclosed set containing F}\}$, preinterior of F is $\text{pint}(F) = \bigcup\{F' : F' \text{ is preopen set contained in F}\}$.

According to [5], a subset F of a topological space X is called regular open or an open domain if $F = \text{int}(\text{cl}(F))$, or equivalently if it is the interior of some closed set. A set F is said to be a regular closed or a closed domain if its complement is an open domain, or equivalently, if $F = \text{cl}(\text{int}(F))$. The finite union of open domain sets in X is said to be π-open. The complement of a π-open set is π-closed, or equivalently, a π-closed set is a finite intersection of closed domain subsets, [6]. The following diagram shows the relationship among closed sets:

$$\text{closed domain} \Rightarrow \pi - \text{closed} \Rightarrow \text{closed} \Rightarrow \alpha - \text{closed} \Rightarrow p - \text{closed}$$

On the other hand, the notions of normal, almost normal and mildly normal spaces were introduced by sharma[7], Singal[8] and Singal[9] respectively. A space X is called normal if every pair of disjoint closed sets are contained in disjoint open sets and it is called almost normal if every pair of disjoint closed sets one of which is closed domain are contained in disjoint open sets and it is said to be mildly normal if every pair of disjoint closed domain sets are contained in disjoint open sets.

In 1995 Paul and Bhattacharyya[10] introduced the concept of p −normal space, a topological space X is said to be p −normal if any disjoint closed sets F and F′ of X are contained in two disjoint p −open sets U and V of X. While in 1991 Navalagi [2] introduced the concepts of mildly p-normal and almost p-normal, a space X is said to be an almost p −normal if any disjoint closed sets F and F′ of X, one of which is closed domain, are contained in two disjoint p −open sets U and V of X, and it is said to be a mildly p −normal if any disjoint closed domain sets F and F′ of X are contained in two disjoint p −open sets U and V of X. Kalantan[11], introduced the definitions of π −normal and quasi-normal spaces, a space X is called a π −normal if any two disjoint closed subsets F and F′ of X, one of which is π −closed are contained in disjoint open sets, and it is called quasi-normal if any two disjoint π −closed subsets F and F′ of X there exist two open disjoint subsets U and V of X such that F⊆ U and F′⊆ V .

In 2012 the notion of πp-normal space was introduced by Sadeq [1]. A space X is said to be πp −normal if for every pair of disjoint closed sets F and F′ of X, one of which is π −closed, are contained in two disjoint p −open sets U and V of X. The following diagrams shows the relationship among normal spaces:

$$\text{normal} \implies \pi-\text{normal} \implies \text{almost normal} \implies \text{mildly normal}$$

$$\text{normal} \implies \pi-\text{normal} \implies \text{quasi}-\text{normal} \implies \text{mildly normal}$$

$$\text{normal} \implies \text{p}-\text{normal} \implies \text{πp}-\text{normal} \implies \text{almost p}-\text{normal}$$

$$\text{normal} \implies \pi-\text{normal} \implies \text{πp}-\text{normal}$$

Recently many topological concepts have been modified to give new concepts in the structure of generalized topological spaces. In this section we review some definitions in generalized topological spaces and we review some modified open sets and modified normal spaces, we begin with the definition of the generalized topological space.

Definition 1.1[12]

Let X be a nonempty set. A collection ϑ of subsets of X is called a generalized topology (in brief, GT) on X if $\emptyset$ belongs to ϑ and the arbitrary unions of elements of ϑ is an element in ϑ. (X, ϑ) is called generalized topological space (in brief, GTS).

Every set in ϑ is called ϑ -open while the complement of ϑ -open is called ϑ -closed. The largest ϑ -open set contained in a set F is called the interior of F and is denoted by $i_\vartheta(F)$ whereas the smallest ϑ -closed set containing F is called the closure of F and is denoted by $c_\vartheta(F)$. A generalized topology ϑ is said to be strong [13] if X $\in$ ϑ, accordingly, (X, ϑ) is called strong generalized topological space (in brief, SGTS).

Definition 1.2[14]

A subset A of a GTS(X, ϑ) is called

(i) ϑ -semi-open if $F \subset c_\vartheta(i_\vartheta(F))$, and its complement is ϑ-semi- closed.

(ii) ϑ-p-open if $F \subset i_\vartheta(c_\vartheta(F))$, and its complement is ϑ-α- closed.

(iii) ϑ-α-open if $F \subset i_\vartheta\left(c_\vartheta(i_\vartheta(F))\right)$, and its complement is ϑ-p- closed.

The intersection of all ϑ-p- closed sets containing F is called $\vartheta-\text{p}-$ closure of F and denoted by $pc_\vartheta(F)$. The $\vartheta-\text{p}-$ interior of F, denoted by $pi_\vartheta(F)$, is defined to be the union of all $\vartheta-\text{p}-$ open sets contained in F.

Definition 1.3[15]

Let A be a subset of a $GTS(X, \vartheta)$. Then A is said to be ϑ −regular open or $\vartheta-$ open domain if $F = i_\vartheta(c_\vartheta(F))$. The complement of a $\vartheta-$ open domain is called $\vartheta-$ closed domain.

Sarsak [16], define $\vartheta-$ closed domain as a subset A of $GTS(X, \vartheta)$ that fulfills the condition $F = c_\vartheta(i_\vartheta(F))$.

Definition 1.4[17]
A subset F of $GTS(X, \vartheta)$ is said to be $\vartheta-\pi-$open if F is the union of finitely many $\vartheta-$ open domain sets, and it is called $\vartheta-\pi-$closed if its complement is a $\vartheta-\pi-$open, or equivalently if F is the intersection of finitely many $\vartheta-$ closed domain sets.
The relationship among all above sets can be illustrated by the following schemes:

$$\vartheta-\text{closed domain} \Rightarrow \vartheta-\pi-\text{closed} \Rightarrow \vartheta-\text{closed} \Rightarrow \vartheta-\alpha-\text{closed} \Rightarrow \vartheta-\text{p}-\text{closed}$$

$$\begin{array}{ccccc} \vartheta-\text{open} & \Longrightarrow & \vartheta-\alpha-\text{open} & \Longrightarrow & \vartheta-\text{semi}-\text{open} \\ & & \Downarrow & & \\ & & \vartheta-\text{p}-\text{open} & & \end{array}$$

$$\begin{array}{ccccc} \vartheta-\text{closed} & \Longrightarrow & \vartheta-\alpha-\text{closed} & \Longrightarrow & \vartheta-\text{semi}-\text{closed} \\ & & \Downarrow & & \\ & & \vartheta-\text{p}-\text{closed} & & \end{array}$$

$$\vartheta-\text{open domain} \Leftrightarrow \vartheta-\text{open and } \vartheta-\text{semi}-\text{closed} \Leftrightarrow \vartheta-\alpha-\text{open and } \vartheta-\text{semi}-\text{closed} \Leftrightarrow \vartheta-\text{p}-\text{open and } \vartheta-\text{semi}-\text{closed}$$

$$\vartheta-\text{closed domain} \Leftrightarrow \vartheta-\text{closed and } \vartheta-\text{semi}-\text{open} \Leftrightarrow \vartheta-\alpha-\text{closed and } \vartheta-\text{semi}-\text{open} \Leftrightarrow \vartheta-\text{p}-\text{closed and } \vartheta-\text{semi}-\text{open}$$

Properties of normal GT's were discussed in ([18], [19], [20], [21], [22], [23]). A $GT\vartheta$ is normal iff, whenever F andF' are ϑ -closed sets such that $F \cap F' = \emptyset$, there exists ϑ -open sets U and V satisfying $F \subset U, F' \subset V$ and $U \cap V = \emptyset$.
In 2012 Bishwambhar[24], defined almost normal and mildly normal spaces, in generalized topological spaces, by modifying the condition related to the open sets in the original definition. As we show below.

Definition 1.5[24]
Let ϑbe a GT on a topological space X. Then
1. X is named almost ϑ -normal if F is a closed set and B is a closed domain set in X with $F \cap F' = \emptyset$, , then there are two disjoint $\vartheta-$open sets U and V such that $F \subseteq U$ and $F' \subseteq V$.
2. X is named mildly ϑ -normal if A and B are closed domain sets in X with $F \cap F' = \emptyset$, , then there are two disjoint $\vartheta-$ open sets U and V such that $F \subseteq U$ and $F' \subseteq V$.

We will denote the class of $\vartheta-$closed (resp. $\vartheta-$p$-$open, $\vartheta-$p$-$closed,$\vartheta-\pi-$open,$\vartheta-\pi-$closed,$\vartheta-$ semi$-$open, $\vartheta-$ semi$-$closed, $\vartheta-\alpha-$open,$\vartheta-\alpha-$closed, $\vartheta-$open domain, $\vartheta-$closed domain) sets in X by ϑ'
(resp.ϑPO(X), ϑPC(X), $\vartheta\pi$O(X), $\vartheta\pi$C(X), ϑSO(X), ϑSC(X),$\vartheta\alpha$O(X), $\vartheta\alpha$C(X),ϑRO(X), ϑRC(X)).

2. $\vartheta\pi$p $-$Normal Generalized Topological Spaces

In this section, another definitions about almost normal and mildly normal spaces, in generalized topological spaces, will be given by modifying the conditions related to open and closed sets in the original definition, called $\vartheta-$ almost normal and $\vartheta-$ mildly normal. By the same way, p$-$ normal,

almost p − normal, mildly p − normal, π − normal, quasi normal and πp −normal spaces, in generalized topological spaces will be defined, called $\vartheta - p - normal, \vartheta -$ almost p − normal, $\vartheta -$ mildly p − normal, $\vartheta\pi -$ normal, $\vartheta -$ quasi normal and $\vartheta\pi p - normal$, and the relationship among them will be discussed, as we show in the following section.

Definition 2.1
A GTS(X, ϑ) is called
1. $\vartheta -$ almost normal if $\forall F \in \vartheta'$ and $\forall F' \in \vartheta RC(X)$ with $F \cap F' = \emptyset, \exists U, V \in \vartheta \ni F \subseteq U$ and $F' \subseteq V$ and $U \cap V = \emptyset$.
2. $\vartheta -$ mildly normal if for any two sets $F, F' \in \vartheta RC(X)$ with $F \cap F' = \emptyset$ there are two sets $U, V \in \vartheta \ni F \subseteq U$ and $F' \subseteq V$ and $U \cap V = \emptyset$.
3. $\vartheta\pi -$ normal if $\forall F \in \vartheta'$and $\forall F' \in \vartheta\pi C(X)$ with $F \cap F' = \emptyset \exists U, V \in \vartheta \ni F \subseteq U$ and $F' \subseteq V$ and $U \cap V = \emptyset$.
4. $\vartheta -$ quasi normal if for any two sets $F, F' \in \vartheta\pi C(X)$ with $F \cap F' = \emptyset$ there are two sets $U, V \in \vartheta \ni F \subseteq U$ and $F' \subseteq V$ and $U \cap V = \emptyset$.
5. $\vartheta - p -$ normal if for any two sets F, $F' \in \vartheta'$ with $F \cap F' = \emptyset$ there are two sets $U, V \in \vartheta PO(X) \ni F \subseteq U$ and $F' \subseteq V$ and $U \cap V = \emptyset$.
6. $\vartheta - almost\ p - normal$ if $\forall F \in \vartheta'$and $\forall F' \in \vartheta RC(X)$with $F \cap F' = \emptyset$, $\exists U, V \in \vartheta PO(X) \ni F \subseteq U\ and\ F' \subseteq V$ and $U \cap V = \emptyset$.
7. $\vartheta - mildly\ p - normal$ if for any two sets $F, F' \in \vartheta RC(X)$ with $F \cap F' = \emptyset$ there are two sets $U, V \in \vartheta PO(X) \ni F \subseteq U\ and\ F' \subseteq V$ and $U \cap V = \emptyset$.
8. $\vartheta\pi p - normal$ if $\forall F \in \vartheta'$and $\forall F' \in \vartheta\pi C(X)$ with $F \cap F' = \emptyset, \exists U, V \in \vartheta PO(X) \ni F \subseteq U\ and\ F' \subseteq V$ and $U \cap V = \emptyset$.
9. $\vartheta - quasi\ p - normal$ if for any two sets $F, F' \in \vartheta\pi C(X)$ with $F \cap F' = \emptyset$ there are two sets $U, V \in \vartheta PO(X) \ni F \subseteq U\ and\ F' \subseteq V$ and $U \cap V = \emptyset$.

Remark 2.2
The following trends are true for the generalized topological space (X, ϑ).

$$\vartheta - normal \implies \vartheta\pi - normal \implies \vartheta - almost\ normal \implies \vartheta - mildly\ normal$$

These directions are not reversible, as shown in the following example

Example2.3
Let $\mathbb{R}$ be the set of all real numbers, and let $\vartheta = \{\mathbb{R}, \emptyset, \{0\}\} \cup \{\mathbb{R}\backslash\{x\}: x \neq 0\}$, then
$\vartheta' = \{\mathbb{R}, \emptyset, \mathbb{R}\backslash\{0\}\} \cup \{\{x\}: x \neq 0\}$, $\vartheta RC(X) = \{\mathbb{R}, \emptyset\}$, and $\vartheta\pi C(X) = \{\mathbb{R}, \emptyset\}$.
Note that $(\mathbb{R}, \vartheta)$ is not $\vartheta -$ normal because for any two nonempty disjoint ϑ −closed sets in $\mathbb{R}$, there are no two disjoint ϑ −open sets containing them. While it is $\vartheta\pi -$ normal, $\vartheta -$ almost normal and $\vartheta -$ mildly normal.

Remark 2.4
The following outline is correct for the generalized topological space (X, ϑ).

$$\vartheta - p - normal \implies \vartheta\pi p - normal \implies \vartheta - almost\ p - normal \implies \vartheta - mildly\ p - normal$$

The inverse of the above directions is generally not correct as shown by the following examples.

Example2.5
Let $X = \{a, b, c\}, \vartheta = \{X, \emptyset, \{a\}, \{a, b\}, \{a, c\}\}, \vartheta' = \{X, \emptyset, \{b, c\}, \{c\}, \{b\}\}$,
$\vartheta PO(X) = \{X, \emptyset, \{a\}, \{a, b\}, \{a, c\}\}, \vartheta RC(X) = \{X, \emptyset\}, \vartheta\pi C(X) = \{X, \emptyset\}$.
Note that (X, ϑ) is not $\vartheta - p -$ normal because $\{c\}\ and\ \{b\}$ are two disjoint ϑ −closed sets in X, but there are no two disjoint $\vartheta - p$ −open containing them. On the other hand, we see that (X, ϑ) is $\vartheta\pi p -$ normal, $\vartheta -$ almost $p -$ normal and $\vartheta -$ mildly $p -$ normal.

Example2.6
Take the set of all real numbers $\mathbb{R}$ with $\vartheta = \{U \subseteq X: \forall\, x \in U\ \exists N \in \eta_x\ \ni N \subseteq U\}$, where $\{\eta_x\}_{x\in\mathbb{R}}$ is defined as follows:
For each $x \in \mathbb{Q}'$(the set of all irrational numbers) put a sequence $\{x_n\}_{n\in\mathbb{N}} \subset \mathbb{Q}$ (the set of all rational numbers) such that $x_n \to x$ (where the convergence is taken in $\mathbb{R}$ with the usual topology), let $A_n(x) = \{x_k: k \geq n\}$, and let $U_n(x) = \{x\} \cup A_n(x)$. For $x \in \mathbb{Q}'$, $\eta_x = \{U_n(x): n \in \mathbb{N}\}$ and for $x \in \mathbb{Q}$, $\eta_x = \{\{x\}\}$. Then $(\mathbb{R}, \vartheta)$ is $\vartheta -$ almost normal and $\vartheta -$ almost p −normal, but it is neither $\vartheta\pi$ −normal nor $\vartheta\pi p$ −normal.

Remark 2.7
Diagram bellow is true for the generalized topological space (X, ϑ).

$$\vartheta - normal \implies \vartheta\pi - normal \implies \vartheta - quasi\ normal$$

These implications are not reversible as shown by the following example.

Example2.8
Let $P = \{(x, y): x, y \in \mathbb{R}, y > 0\}$ and $L = \{(x, 0): x \in \mathbb{R}\}$ be a subspace of $\mathbb{R}^2$with the usual topology, and let $X = P \cup L$
$For\ z \in P, \eta_{z=}$ any basic open disc around z contained in P with its usual Euclidean topology.
$For\ z \in L, \eta_{z=} \{z\} \cup (P \cap D)$, where D is any open disc around z in the plane $\mathbb{R}^2$ with its usual Euclidean topology.

Let $\vartheta = \{U \subseteq X: \forall\, z \in U\ \exists N \in \eta_z\ \ni N \subseteq U\}$, then (X, ϑ) is neither ϑ −normal nor $\vartheta\pi$ −normal , while it is a ϑ −quasi normal.

Remark 2.9
A condition "every $\vartheta -$ closed must be ϑ −semi− open" can be added in Remarks 2.2, 2.4 and 2.7 to achieve opposite directions.

Proposition 2.10
Every $\vartheta\pi$ −normal space is a $\vartheta\pi p -$ normal space.
Proof:
Let (X, ϑ) be $\vartheta\pi$ −normal space, we have to show that X is $\vartheta\pi p -$ normal space, let F be ϑ −closed set and F' be $\vartheta - \pi$ −closed set of X with $F \cap F' = \emptyset$, by definition of $\vartheta\pi$ −normal we get two disjoint ϑ −open sets $U\ and\ V$ such that $F \subseteq U\ and\ F' \subseteq V$. Since every ϑ −open set is $\vartheta - p$ −open, so we got what we needed.

Remark 2.11
The opposite direction of Proposition 2.10 is generally incorrect. Note the generalized topological space in Example2.8 is a $\vartheta\pi p -$ normal space, but not $\vartheta\pi$ −normal.

Theorem 2.12
For a generalized topological space (X, ϑ), the following are equivalent :
a) (X, ϑ) is $\vartheta\pi p -$ normal.
b) $\forall U, V \in \vartheta$, one of which is $\vartheta - \pi$ −open, $U \cup V = X$, there are $\vartheta - p$ −closed sets F and F' so that $F \subseteq U, F' \subseteq V\ and\ F \cup F' = X$.
c) $\forall F \in \vartheta'$ and $\forall U \in \vartheta\pi O(X)$ with $F \subseteq U$, there is a $\vartheta - p$ −open set V so that $F \subseteq V \subseteq pc_\vartheta(V) \subseteq U$.

Proof:

If (a)Then(b)
Let $U\ and\ V$ be ϑ −open sets in X, such that V is $\vartheta-\pi$ −open and $U\cup V = X$, consequently we have $X\backslash U\ and\ X\backslash V$ are ϑ −closed sets in a $\vartheta\pi p-$ normal $GTS(X,\vartheta)$ with $X\backslash V$ $\vartheta-\pi-$ closed and $X\backslash U \cap X\backslash V = \emptyset$, so by Definition 2.1,no.8 there exist two disjoint $\vartheta-p$ −open sets $G\ and\ H$ such that $X\backslash U\subseteq G\ and\ X\backslash V\subseteq H$. Let $F = X\backslash G$ and $F' = X\backslash H$, then F and F' are $\vartheta-p$ −closed sets such that $F\subseteq U, F'\subseteq V\ and\ F\cup F' = X$.
If(b)Then(c)
Let F be a ϑ −closed set and U be a $\vartheta-\pi$ −open set so that $F\subseteq U$, thus $F\cap X\backslash U = \emptyset$, which leads to $X\backslash F\cup U = X$, where $X\backslash F$ is ϑ −open. By (b) we can get $\vartheta-p$ −closed sets F_1 and F_2 such that $F_1\subseteq X\backslash F, F_2\subseteq U\ and\ F_1\cup F_2 = X$. We have got $F\subseteq X\backslash F_1$ and $X\backslash F_1\cap X\backslash F_2 = \emptyset$ which results in $X\backslash F_1\subseteq F_2$. Put $V = X\backslash F_1$, then $F\subseteq V\subseteq F_2\subseteq U$. We know that $V\subseteq pc_\vartheta(V)$, it remains to show that $pc_\vartheta(V)\subseteq U$, note that F_2 is $\vartheta-p$ −closed set containing V, but $pc_\vartheta(V)$ is the smallest $\vartheta-p$ −closed set containing V, therefor $pc_\vartheta(V)\subseteq F_2\subseteq U$. Hence $F\subseteq V\subseteq pc_\vartheta(V)\subseteq U$.
If(c)Then(a)
Let F and F' be any ϑ −closed sets of X with F' is $\vartheta-\pi$ −closed and $F\cap F' = \emptyset$, so $F\subseteq X\backslash F'$ which is $\vartheta-\pi$ −open, then by (c) there is a $\vartheta-p$ −open set V so that $F\subseteq V\subseteq pc_\vartheta(V)\subseteq X\backslash F'$. Let $G = V$ and $H = X\backslash pc_\vartheta(V)$, then $G, H\in\vartheta OP(X)$ with $G\cap H = \emptyset$ and $F\subseteq G, F'\subseteq H$. Hence (X,ϑ) is $\vartheta\pi p-$ normal.

3. Preservation Theorems of $\vartheta\pi p$ −Normality

Definition 3.1 [25]
A function $f: (X,\vartheta_1)\to(Y,\vartheta_2)$ from a $GTS(X,\vartheta_1)$ into a $GTS(Y,\vartheta_2)$ is called
1. $(\vartheta_1,\vartheta_2)$−continuous if $f^{-1}(H)\in\vartheta_1\forall H\in\vartheta_2$.
2. $(\vartheta_1,\vartheta_2)$−open if $f(G)\in\vartheta_2\ \forall\ G\in\vartheta_1$.
3. $(\vartheta_1,\vartheta_2)-$ R−irresolute if $f^{-1}(H)\in\vartheta_1RC(X)\ \forall\ H\in\vartheta_2RC(Y)$.
4. Completely $(\vartheta_1,\vartheta_2)-$ irresolute if $f^{-1}(H)\in\vartheta_1\pi C(X)\ \forall\ H\in\vartheta_2\pi C(Y)$.
5. Almost $(\vartheta_1,\vartheta_2)$−closed if $f(G)\in\vartheta_2\pi C(Y)\ \forall\ G\in\vartheta_1\pi C(X)$.
6. $(\vartheta_1,\vartheta_2)$−closed if $f(F)\in\vartheta_2{}'\ \forall\ F\in\vartheta_1{}'$.[26]

Theorem 3.2[27]
A function $f: (X,\vartheta_1)\to(Y,\vartheta_2)$ is called $(\vartheta_1,\vartheta_2)$−continuous if for every ϑ_2-closed set $K\ in\ Y$, $f^{-1}(K)$ is ϑ_1 −closed in X.
The following theorems show the functions that maintain the property of being ϑ −normal, ϑ −almost normal, ϑ −mildly normal, $\vartheta\pi$ −normal and $\vartheta-quasi$ normal.

Theorem 3.3
Let $f: (X,\vartheta_1)\to(Y,\vartheta_2)$ be a bijective $(\vartheta_1,\vartheta_2)$−continuous $(\vartheta_1,\vartheta_2)$−open function, if X is ϑ_1 −normal, then Y is ϑ_2 −normal.

Proof:
Let $F\ and\ F'\in\vartheta_2{}'$ with $F\cap F' = \emptyset$, by Theorem 2.3 we get that $f^{-1}(F), f^{-1}(F')\in\vartheta_1{}'$ with $f^{-1}(F)\cap f^{-1}(F') = \emptyset$. But X is ϑ_1 −normal space, so there exists ϑ_1 −open sets $U\ and\ V$ satisfying $f^{-1}(F)\subset U, f^{-1}(F')\subset V$ and $U\cap V = \emptyset$.
Now we have $f(U)\ and\ f(V)$ are ϑ_2 −open sets in Y with $F = f\left(f^{-1}(F)\right)\subset f(U)\ and$ $F' = f\left(f^{-1}(F')\right)\subset f(V)$ and $f(U)\cap f(V) = f(U\cap V) = \emptyset$. Hence Y ϑ_2 −normal space.

Corollary 3.4
The image of $\vartheta_1-normal$ space under the bijective $(\vartheta_1,\vartheta_2)$−continuous $(\vartheta_1,\vartheta_2)$−open function is $\vartheta_2\pi p-$ normal space.

Proof:
Follows from Theorem 3.3, Remark 2.7 and Proposition 2.10.

Theorem 3.5
Let $f:(X,\vartheta_1)\to(Y,\vartheta_2)$ be a bijective $(\vartheta_1,\ \vartheta_2)-$continuous $(\vartheta_1,\ \vartheta_2)-$open and $(\vartheta_1,\ \vartheta_2)-$ R$-$irresolute function, if X is ϑ_1 $-$almost normal, then Y is ϑ_2 $-$almost normal.

Proof:
Let F be ϑ_2 $-$closed $and\ F'$ be ϑ_2 $-$closed domain in Y such that $F\ \cap\ F'\ =\ \emptyset$, we get that $f^{-1}(F)$ is ϑ_1 $-$closed $and\ f^{-1}(F')$ is ϑ_1 $-$closed domain in X with $f^{-1}(F)\cap f^{-1}(F')=\emptyset$. But X is ϑ_1 $-$almost normal space, so there are ϑ_1 $-$open sets $U\ and\ V$ such that

$$f^{-1}(F)\subset U, f^{-1}(F')\subset V \text{ and } U\ \cap\ V\ =\ \emptyset.$$

Now we have $f(U)\ and\ f(V)$ are ϑ_2 $-$open sets in Y with $F=f\left(f^{-1}(F)\right)\subset f(U)\ and$ $F'=f\left(f^{-1}(F')\right)\subset f(V)$ and $f(U)\ \cap f(V)=f(U\cap V)=\emptyset$. Hence Y ϑ_2 $-$almost normal space.

Theorem 3.6
Let $f:(X,\vartheta_1)\to(Y,\vartheta_2)$ be a bijective $(\vartheta_1,\ \vartheta_2)-$open $(\vartheta_1,\ \vartheta_2)-$ R$-$irresolute function, if X is $\vartheta_1-mildly\ normal$, then Y is $\vartheta_2-mildly\ normal$.

Proof:
Take $F,F'\in\ \vartheta_2RC(Y)$ with $F\ \cap\ F'\ =\ \emptyset$, we get that $f^{-1}(F),f^{-1}(F')\in\ \vartheta_1R\,C(X)$ with $f^{-1}(F)\cap f^{-1}(F')=\emptyset$. But X is ϑ_1- mildly normal space, so there exists ϑ_1 $-$open sets $U\ and\ V$ such that $f^{-1}(F)\subset U, f^{-1}(F')\subset V$ and $U\ \cap\ V\ =\ \emptyset$.
Now we have $f(U)\ and\ f(V)$ are ϑ_2 $-$open sets in Y such that $F=f\left(f^{-1}(F)\right)\subset f(U)\ and$ $F'=f\left(f^{-1}(F')\right)\subset f(V)$ and $f(U)\ \cap f(V)=f(U\cap V)=\emptyset$. Hence Y ϑ_2- mildly normal space.

Theorem 3.7
Let $f:(X,\vartheta_1)\to(Y,\vartheta_2)$ be a bijective $(\vartheta_1,\ \vartheta_2)-$continuous $(\vartheta_1,\ \vartheta_2)-$open and Completely $(\vartheta_1,\ \vartheta_2)-$irresolute function, if X is $\vartheta_1\pi-$ normal, then Y is $\vartheta_2\pi-$ normal.

Proof:
Let F be ϑ_2 $-$closed $and\ F'$ be $\vartheta_2-\pi$ $-$closed in Y with $F\ \cap\ F'\ =\ \emptyset$, we get that $f^{-1}(F)$ is ϑ_1 $-$closed $and\ f^{-1}(F')$ is $\vartheta_1-\pi$ $-$closed domain in X with $f^{-1}(F)\cap f^{-1}(F')=\emptyset$. But X is $\vartheta_1\pi-$ normal space, so there exists ϑ_1 $-$open sets $U\ and\ V$ such that

$$f^{-1}(F)\subset U, f^{-1}(F')\subset V \text{ and } U\ \cap\ V\ =\ \emptyset.$$

Now we have $f(U)\ and\ f(V)$ are ϑ_2 $-$open sets in Y whereas $F=f\left(f^{-1}(F)\right)\subset f(U)\ and$ $F'=f\left(f^{-1}(F')\right)\subset f(V)$ and $f(U)\ \cap f(V)=f(U\cap V)=\emptyset$. Hence Y $\vartheta_2\pi-$ normal space.

Corollary 3.8
The image of $\vartheta_1\pi-\ normal$ space under the $(\vartheta_1,\ \vartheta_2)-$continuous $(\vartheta_1,\ \vartheta_2)-$open and Completely $(\vartheta_1,\ \vartheta_2)-$irresolute function is $\vartheta_2\pi p-$ normal space.

Proof:
Follows from Theorem 3.7 and Proposition 2.10

Theorem 3.9
Let $f:(X,\vartheta_1)\to(Y,\vartheta_2)$ be a bijective $(\vartheta_1,\ \vartheta_2)-$open Completely $(\vartheta_1,\ \vartheta_2)-$ irresolute function, if X is $\vartheta_1-\ quasi\ normal$, then Y is $\vartheta_2-quasi\ normal$.

Proof:
Let $F, F' \in \vartheta_2\pi C(Y)$ with $F \cap F' = \emptyset$, we get that $f^{-1}(F), f^{-1}(F') \in \vartheta_1\pi C(X)$ with $f^{-1}(F) \cap f^{-1}(F') = \emptyset$. But X is $\vartheta_1 - quasi$ normal space, so there exists ϑ_1 −open sets U and V such that $f^{-1}(F) \subset U$, $f^{-1}(F') \subset V$ and $U \cap V = \emptyset$. Now we have $f(U)$ and $f(V)$ are ϑ_2 −open sets in Y whereas $F = f(f^{-1}(F)) \subset f(U)$ and $F' = f(f^{-1}(F')) \subset f(V)$ and $f(U) \cap f(V) = f(U \cap V) = \emptyset$. Hence Y $\vartheta_2 - quasi$ normal space.

To indicate the type of functions that preserve the property of being $\vartheta - p$ −normal, ϑ −almost p −normal, ϑ −mildly $p-$ normal, $\vartheta\pi p$ −normal and $\vartheta - quasip -$ normal, we need the following definition.

Definition 3.10
A function $f: (X, \vartheta_1) \to (Y, \vartheta_2)$ from a $GTS(X, \vartheta_1)$ into a $GTS(Y, \vartheta_2)$ is called $(\vartheta_1, \vartheta_2) - M$ −preopen if $f(G) \in \vartheta_2\, PO(Y)\ \forall\ G \in \vartheta_1 PO(X)$.

Theorem 3.11
Let $f: (X, \vartheta_1) \to (Y, \vartheta_2)$ be a bijective $(\vartheta_1, \vartheta_2)$−continuous $(\vartheta_1, \vartheta_2) - M$ −preopen function, if X is $\vartheta_1 - p - normal$, then Y is $\vartheta_2 - p - normal$.

Proof:
Let F and $F' \in \vartheta_2{}'$ with $F \cap F' = \emptyset$, by Theorem 2.3 we get that $f^{-1}(F), f^{-1}(F') \in \vartheta_1{}'$ with $f^{-1}(F) \cap f^{-1}(F') = \emptyset$. But X is $\vartheta_1 - p -$ normal space, so there exists $\vartheta_1 - p -$ open sets U and V satisfying $f^{-1}(F) \subset U, f^{-1}(F') \subset V$ and $U \cap V = \emptyset$. Therefor $f(U)$ and $f(V)$ are $\vartheta_2 - p -$ open sets in Y so that $F = f(f^{-1}(F)) \subset f(U)$ and $F' = f(f^{-1}(F')) \subset f(V)$ and $f(U) \cap f(V) = f(U \cap V) = \emptyset$. Hence Y $\vartheta_2 - p -$ normal space.

Corollary 3.12
The image of $\vartheta_1 - P - normal$ space under the bijective $(\vartheta_1, \vartheta_2)$−continuous $(\vartheta_1, \vartheta_2) - M$ −preopen function is $\vartheta_2\pi p -$ normal space.

Proof:
Follows from Theorem 3.11 and Remark 2.4.

Theorem 3.13
Let $f: (X, \vartheta_1) \to (Y, \vartheta_2)$ be a bijective $(\vartheta_1, \vartheta_2)$−continuous $(\vartheta_1, \vartheta_2) - M$ −preopen and $(\vartheta_1, \vartheta_2)-$ R−irresolute function, if X is ϑ_1 −almost $p-$ normal, then Y is ϑ_2 −almost $p-$ normal.

Proof:
Let F be ϑ_2 −closed and F' be ϑ_2 −closed domain in Y such that $F \cap F' = \emptyset$, we get that $f^{-1}(F)$ is ϑ_1 −closed and $f^{-1}(F')$ is ϑ_1 −closed domain in X with $f^{-1}(F) \cap f^{-1}(F') = \emptyset$. But X is ϑ_1 −almost $p-$ normal space, so there are $\vartheta_1 - p -$ open sets U and V such that
$f^{-1}(F) \subset U, f^{-1}(F') \subset V$ and $U \cap V = \emptyset$.
Thus $f(U)$ and $f(V)$ are $\vartheta_2 - p -$ open sets in Y whereas $F = f(f^{-1}(F)) \subset f(U)$ and $F' = f(f^{-1}(F')) \subset f(V)$ and $f(U) \cap f(V) = f(U \cap V) = \emptyset$. Hence Y ϑ_2 −almost p −normal space.

Theorem 3.14
Let $f: (X, \vartheta_1) \to (Y, \vartheta_2)$ be a bijective $(\vartheta_1, \vartheta_2) - M$ −preopen $(\vartheta_1, \vartheta_2)-$ R−irresolute function, if X is $\vartheta_1 - mildly\ p - normal$, then Y is $\vartheta_2 - mildly\ p - normal$.

Proof:
Take $F\ and\ F' \in \vartheta_2\ RC(Y)$ with $F \cap F' = \emptyset$, we get that $f^{-1}(F), f^{-1}(F') \in \vartheta_1 R\ C(X)$ with $f^{-1}(F) \cap f^{-1}(F') = \emptyset$. But X is $\vartheta_1 -$ mildly $p -$normal space, so there exists $\vartheta_1 - p -$ open sets $U\ and\ V$ such that $f^{-1}(F) \subset U, f^{-1}(F') \subset V$ and $U \cap V = \emptyset$. This gives us that $f(U)\ and\ f(V)$ are $\vartheta_2 - p -$ open sets in Y whereas $F = f\left(f^{-1}(F)\right) \subset f(U)\ and\ F' = f\left(f^{-1}(F')\right) \subset f(V)$ and $f(U) \cap f(V) = f(U \cap V) = \emptyset$. Hence $Y\ \vartheta_2 -$ mildly $p -$ normal space.

Theorem 3.15
Let $f : (X, \vartheta_1) \to (Y, \vartheta_2)$ be a bijective $(\vartheta_1, \vartheta_2)-$continuous $(\vartheta_1, \vartheta_2)-M -$preopen and Completely $(\vartheta_1, \vartheta_2)-$irresolute function, if X is $\vartheta_1 \pi p - normal$, then Y is $\vartheta_2 \pi p - normal$.

Proof:
Let F be $\vartheta_2 -$closed $and\ F'$ be $\vartheta_2 - \pi -$closed in Y with $F \cap F' = \emptyset$, we get that $f^{-1}(F)$ is $\vartheta_1 -$closed $and\ f^{-1}(F')$ is $\vartheta_1 - \pi -$closed domain in X with $f^{-1}(F) \cap f^{-1}(F') = \emptyset$. But X is $\vartheta_1 \pi p -$ normal space, so there are $\vartheta_1 - p -$ open sets $U\ and\ V$ such that
$$f^{-1}(F) \subset U, f^{-1}(F') \subset V \text{ and } U \cap V = \emptyset.$$
This implies $f(U)\ and\ f(V)$ are $\vartheta_2 - p -$ open sets in Y whereas $F = f\left(f^{-1}(F)\right) \subset f(U)\ and\ F' = f\left(f^{-1}(F')\right) \subset f(V)$ and $f(U) \cap f(V) = f(U \cap V) = \emptyset$. Hence $Y\ \vartheta_2 \pi p -$ normal space.

Corollary 3.16
The image of $\vartheta_1 \pi p - normal$ space under the bijective $(\vartheta_1, \vartheta_2)-$continuous $(\vartheta_1, \vartheta_2)-M -$preopen and Completely $(\vartheta_1, \vartheta_2)-$irresolute function is $\vartheta_2 -$almost normal(resp. $\vartheta_2 -$ mildly normal, $\vartheta_2 -$almost $p -$normal, $\vartheta_2 -$ mildly $p -$ normal, $\vartheta_2 - quasi$ normal).

Proof:
Follows from Theorem 3.15 and Remarks 2.2, 2.4, 2.7 and Proposition 2.10.

Theorem 3.17
Let $f : (X, \vartheta_1) \to (Y, \vartheta_2)$ be a bijective $(\vartheta_1, \vartheta_2)-M -$preopen Completely $(\vartheta_1, \vartheta_2)-$ irresolute function, if X is $\vartheta_1 - quasi\ p -$ normal, then Y is $\vartheta_2 - quasi\ p -$ normal.

Proof:
Let $F\ and\ F' \in \vartheta_2 \pi C(Y)$ with $F \cap F' = \emptyset$, we get that $f^{-1}(F), f^{-1}(F') \in \vartheta_1 \pi\ C(X)$ with $f^{-1}(F) \cap f^{-1}(F') = \emptyset$. But X is $\vartheta_1 - quasip -$ normal space, so there are $\vartheta_1 - p -$ open sets $U\ and\ V$ whereas $f^{-1}(F) \subset U, f^{-1}(F') \subset V$ and $U \cap V = \emptyset$. We got $f(U)\ and\ f(V)$ are $\vartheta_2 - p -$ open sets in Y such that $F = f\left(f^{-1}(F)\right) \subset f(U)\ and\ F' = f\left(f^{-1}(F')\right) \subset f(V)$ and $f(U) \cap f(V) = f(U \cap V) = \emptyset$. Hence $Y\ \vartheta_2 - quasip -$ normal space.

Definition 3.18
Let $(X, \vartheta_1) and (Y, \vartheta_2)$ be two generalized topological spaces. A function $f : (X, \vartheta_1) \to (Y, \vartheta_2)$ is called $(\vartheta_1, \vartheta_2)\ pre -$ irresolute if $f^{-1}(H) \in \vartheta_1 PO(X)\ \forall\ H \in \vartheta_2 PO(Y)$.

Theorem 3.19
Let $f : (X, \vartheta_1) \to (Y, \vartheta_2)$ be a bijective $(\vartheta_1, \vartheta_2)-$closed, Almost$(\vartheta_1, \vartheta_2)-$ closed and $(\vartheta_1, \vartheta_2)\ pre -$irresolute function, if Y is $\vartheta_2 \pi p - normal$, then X is $\vartheta_1 \pi p - normal$.

Proof:
Take $F \in \vartheta_1{}'\ and\ F' \in \vartheta_1 \pi C(X)$ with $F \cap F' = \emptyset$, so $f(F)$ is $\vartheta_2 -$closed $and\ f(F')$ be $\vartheta_2 - \pi -$closed in Y such that $f(F) \cap f(F') = f(F \cap F') = \emptyset$. But Y is $\vartheta_2 \pi p -$ normal space, therefor

we get two disjoint $\vartheta_2 - p -$ open sets U and V in Y such that $f(F) \subset U$, $f(F') \subset V$. Since f is $(\vartheta_1, \vartheta_2)\, pre -$irresolute function, so $f^{-1}(U)$ and $f^{-1}(V)$ are $\vartheta_1 - p -$open in X with $f^{-1}(U) \cap f^{-1}(V) = \emptyset$ and $F = f^{-1}\big(f(F)\big) \subset f^{-1}(U)$ and $F' = f^{-1}\big(f(F')\big) \subset f^{-1}(V)$. Hence X is $\vartheta_1 \pi p -$ normal space.

Cech Fuzzy Soft Bi-Closure Spaces

Čech Fuzzy Soft Bi-Closure Spaces

M T Hmood and R N Majeed *

E-mail: rasha.n.m@ihcoedu.uobaghdad.edu.iq

Abstract. In the present study, Čech fuzzy soft bi-closure spaces (Čfs bi-csp's) are defined. The basic properties of Čfs bi-csp's are studied such as we show from each Čfs bi-csp's $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ we can obtain two types of associative fuzzy soft topological spaces, the first is a fuzzy soft bitopological space $(\mathcal{U}, \tau_{\mathcal{L}_1}, \tau_{\mathcal{L}_2}, S)$ and the second is a fuzzy soft topological space $(\mathcal{U}, \tau_{\mathcal{L}_1\mathcal{L}_2}, S)$. Also, the concepts of the fuzzy soft interior, subspace, and continuity which are the building blocks of classical bi-closure spaces are defined on Čfs bi-csp's. Besides, several examples have been given so that the subject can be better understood.

1. Introduction

Molodtsove [13] introduced the concept of the soft set to solve the problems of incomplete information and investigated various applications in game theory, smoothness of functions, operation researches, Perron integration, probability theory, the theory of measurement, and so on. Maji et al. [6] presented the definition of fuzzy soft sets. Later in 2011, the topological structure based on fuzzy soft sets was given by Tanay and Kandemir [16]. Mukherjee and Park [14] in 2015 introduced the notion of fuzzy soft bitopological spaces. Closure spaces were first introduced by $\check{C}$ech [1] in 1966 since then various notions in general topology have been extended to closure spaces. After Zadeh introduced the concept of fuzzy sets, Mashhour and Ghanim [12] defined $\check{C}$ech fuzzy closure spaces. In 2014, Gowri and Jegadeesan [3] and Krishnaveni and Sekar [5], using the concept of soft sets to introduced and investigate the notion of soft $\check{C}$ech closure spaces. Recently, motivated by the concept of fuzzy soft set and fuzzy soft topology [2] in Chang's sense Majeed [9] was defined the concept of $\check{C}$ech fuzzy soft closure spaces. Also, Majeed and Maibed provided further studies on the structures of Čech fuzzy soft closure spaces such as separation axioms and connectedness see [7, 8, 10, 11]. In the present work, we introduce and study $\check{C}$fs bi-csp's. In section 2, we review some concepts from the literature of fuzzy sets, fuzzy soft sets, and fuzzy soft topological spaces that are needed to be used in the current paper. Section 3 is devoted to introduce and investigate the fundamental structure of $\check{C}$fs bi-csp's, such as open (resp. closed) fuzzy soft sets, fuzzy soft interior operator, topologies induced from $\check{C}$fs bi-csp's. In section 4, the concept of fuzzy soft subspaces from $\check{C}$fs bi-csp's are given and studied. Finally, in Section 5, we introduce some types of continuous (resp. open) fuzzy soft mappings and give its basic properties.

2. Preliminaries

Throughout this paper, $\mathcal{U}$ will refer to the initial universe, $I = [0,1], I_0 = (0,1]$, and S the set of parameters for $\mathcal{U}$ and $\mathcal{A}$ be an non empty of S. β is called a fuzzy set of $\mathcal{U}$ [18] if β is a mapping from $\mathcal{U}$. The family of all fuzzy sets of $\mathcal{U}$ is denoted by $I^{\mathcal{U}}$.

Definition 2.1 [15,17] A fuzzy soft set (fss, briefly) $\beta_{\mathcal{A}}$ on the universe se, $\mathcal{U}$, is a mapping from the parameters set S to $I^{\mathcal{U}}$, i. e., $\beta_{\mathcal{A}}: S \to I^{\mathcal{U}}$, where $\beta_{\mathcal{A}}(s) \neq \bar{0}$ if $s \in \mathcal{A} \subseteq S$ and $\beta_{\mathcal{A}}(s) = \bar{0}$ if $s \notin \mathcal{A}$, where $\bar{0}$ is the empty fuzzy set on $\mathcal{U}$. The family of all $fss's$ over $\mathcal{U}$ denoted by $\mathcal{FS}(\mathcal{U}, S)$.

Definition 2.2 [17] *Let* $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}} \in \mathcal{FS}(\mathcal{U}, S)$. Then, some basic set operations of $fss's$ are defined as follows:

1. (Inclusion): $\beta_{\mathcal{A}} \sqsubseteq \mathcal{S}_{\mathcal{B}}$ *iff* $\beta_{\mathcal{A}}(s) \leq \mathcal{S}_{\mathcal{B}}(s)$, for all $s \in S$.
2. (Equality): $\beta_{\mathcal{A}} = \mathcal{S}_{\mathcal{B}}$ *iff* $\beta_{\mathcal{A}} \sqsubseteq \mathcal{S}_{\mathcal{B}}$ and $\mathcal{S}_{\mathcal{B}} \sqsubseteq \beta_{\mathcal{A}}$.
3. (Union): $\rho_{\mathcal{A} \sqcup \mathcal{B}} = \beta_{\mathcal{A}} \sqcup \mathcal{S}_{\mathcal{B}}$ *iff* $\rho_{\mathcal{A} \sqcup \mathcal{B}}(s) = \beta_{\mathcal{A}}(s) \vee \mathcal{S}_{\mathcal{B}}(s)$, for all $s \in S$.
4. (Intersection): $\rho_{\mathcal{A} \sqcap \mathcal{B}} = \beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}}$ *iff* $\rho_{\mathcal{A} \sqcap \mathcal{B}}(s) = \beta_{\mathcal{A}}(s) \wedge \mathcal{S}_{\mathcal{B}}(s)$, for all $s \in S$.
5. (Complement): $\mathcal{S}_{\mathcal{B}} = \beta_{\mathcal{A}}^{c}$ *iff* $\beta_{\mathcal{A}}^{c}(s) = \bar{1} - \beta_{\mathcal{A}}(s)$, for all $s \in S$, where $\bar{1}(x) = 1, \forall x \in \mathcal{U}$.
6. (Null fss): β_s is called null fss, denoted $\tilde{0}_S$, if $\beta_s(s) = \bar{0}$, for all $s \in S$.
7. (Universal fss) β_s is called Universal fss, denoted $\tilde{1}_S$, *if* $\beta_s(s) = \bar{1}$, for all $s \in S$.

Definition 2.3 [9] Let $\mathcal{V}$ be a nonempty subset of $\mathcal{U}$, then $\tilde{\mathcal{V}}_S$ denotes the fss $\mathcal{V}_s$ over $\mathcal{U}$ for which $\mathcal{V}(s) = \bar{1}_{\mathcal{V}}$ for all $s \in S$, (where $\bar{1}_{\mathcal{V}}: \mathcal{U} \to [0,1]$ such that $\bar{1}_{\mathcal{V}}(x) = 1$ if $x \in \mathcal{V}$ and $\bar{1}_{\mathcal{V}}(x) = 0$ if $x \notin \mathcal{V}$).

Theorem 2.4 [17] Let J be an index set and $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}}, (\beta_{\mathcal{A}})_i, (\mathcal{S}_{\mathcal{B}})_i \in \mathcal{FS}(\mathcal{U}, S)\ \forall i \in J$, then

1. $\beta_{\mathcal{A}} \sqcap \left(\sqcup_{i \in J} (\mathcal{S}_{\mathcal{B}})_i\right) = \sqcup_{i \in J} (\beta_{\mathcal{A}} \sqcap (\mathcal{S}_{\mathcal{B}})_i),\ \beta_{\mathcal{A}} \sqcup \left(\sqcap_{i \in J} (\mathcal{S}_{\mathcal{B}})_i\right) = \sqcap_{i \in J} (\beta_{\mathcal{A}} \sqcup (\mathcal{S}_{\mathcal{B}})_i)$.
2. $(\sqcup_{i \in J} (\beta_{\mathcal{A}})_i)^c = \sqcap_{i \in J} (\beta_{\mathcal{A}}^c)_i,\ (\sqcap_{i \in J} (\beta_{\mathcal{A}})_i)^c = \sqcup_{i \in J} (\beta_{\mathcal{A}}^c)_i$.
3. If $\beta_{\mathcal{A}} \sqsubseteq \mathcal{S}_{\mathcal{B}}$, then $\mathcal{S}_{\mathcal{B}}^c \sqsubseteq \beta_{\mathcal{A}}^c$.
4. $\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}} \sqsubseteq \beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}}$ and $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}} \sqsubseteq \beta_{\mathcal{A}} \sqcup \mathcal{S}_{\mathcal{B}}$.

Definition 2.5 [17] Let $\mathcal{FS}(\mathcal{U}, S)$ and $\mathcal{FS}(\mathcal{W}, \mathcal{N})$ be families of all $fss's$ over $\mathcal{U}$ and $\mathcal{W}$, respectively. Let $u: \mathcal{U} \to \mathcal{W}$ and $p: S \to \mathcal{N}$ be two functions. Then, f_{up} is called fuzzy soft mapping from $\mathcal{FS}(\mathcal{U}, S)$ to $\mathcal{FS}(\mathcal{W}, \mathcal{N})$ and denoted by $f_{up}: \mathcal{FS}(\mathcal{U}, S) \longrightarrow \mathcal{FS}(\mathcal{W}, \mathcal{N})$.

1. If $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{U}, S)$, then the image of $\beta_{\mathcal{A}}$ under the fuzzy soft mapping f_{up} is the fss over $\mathcal{W}$ defined by $f_{up}(\beta_{\mathcal{A}})$, where $\forall k \in p(s),\ \forall y \in \mathcal{W}$.

$$f_{up}(\beta_{\mathcal{A}})(k)(y) = \begin{cases} \bigvee_{u(x)=y} \left(\bigvee_{p(s)=k} (\beta_{\mathcal{A}}(s)) \right)(x) & if\ x \in u^{-1}(y), \\ 0 & otherwise. \end{cases}$$

2. If $\mathcal{S}_{\mathcal{B}} \in \mathcal{FS}(\mathcal{W}, \mathcal{N})$, then the pre-image of $\mathcal{S}_{\mathcal{B}}$ under the fuzzy soft mapping f_{up} is the fss over $\mathcal{U}$ defined by $f_{up}^{-1}(\mathcal{S}_{\mathcal{B}})$. where $\forall s \in p^{-1}(\mathcal{N}), \forall x \in \mathcal{U}$.

$$f_{up}^{-1}(\mathcal{S}_{\mathcal{B}})(s)(x) = \begin{cases} \mathcal{S}_{\mathcal{B}}\big(p(s)\big)\big(u(x)\big) & for\ \ p(s) \in \mathcal{B}, \\ 0 & otherwise. \end{cases}$$

The fuzzy soft mapping f_{up} *is* called surjective (resp. injective) if u and p are surjective (resp. injective), also it is said to be constant if u and p are constant.

Theorem 2.6 [4] Let $\mathcal{U}$ and $\mathcal{W}$ crisp sets $\beta_{\mathcal{A}}, (\beta_{\mathcal{A}})_i \in \mathcal{FS}(\mathcal{U}, S)$ and $\mathcal{S}_{\mathcal{B}}, (\mathcal{S}_{\mathcal{B}})_i \in \mathcal{FS}(\mathcal{W}, \mathcal{N}),\ \forall i \in J$ where J is an index set. Then,

1. *If* $(\beta_{\mathcal{A}})_1 \sqsubseteq (\beta_{\mathcal{A}})_2$, then $f_{up}((\beta_{\mathcal{A}})_1) \sqsubseteq f_{up}((\beta_{\mathcal{A}})_2)$.
2. *If* $(\mathcal{S}_{\mathcal{B}})_1 \sqsubseteq (\mathcal{S}_{\mathcal{B}})_2$, then $f_{up}^{-1}((\mathcal{S}_{\mathcal{B}})_1) \sqsubseteq f_{up}^{-1}((\mathcal{S}_{\mathcal{B}})_2)$.
3. $\beta_{\mathcal{A}} \sqsubseteq f_{up}^{-1}\left(f_{up}(\beta_{\mathcal{A}})\right)$, *if* f_{up} is injective, then the equality holds.
4. $f_{up}(f_{up}^{-1}(\mathcal{S}_{\mathcal{B}})) \sqsubseteq \mathcal{S}_{\mathcal{B}}$, *if* f_{up} is surjective, then the equality holds.

5. $(f_{up}(\beta_{\mathcal{A}}))^c \sqsubseteq f_{up}(\beta_{\mathcal{A}}^c)$.
6. $(f_{up}^{-1}(\mathcal{S}_{\mathcal{B}}))^c = f_{up}^{-1}(\mathcal{S}_{\mathcal{B}}^c)$.

Definition 2.7 [15,16] A triple $(\mathcal{U}, \tau, S)$ is called a fuzzy soft topological space where $\mathcal{U}$ is a nonempty set with a fixed set of parameters S and τ is a family of $fss's$ over $\mathcal{U}$ satisfying the following properties.

1. $\tilde{0}_S, \tilde{1}_S \in \tau$,
2. If $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}} \in \tau$, then $\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}} \in \tau$,
3. If $(\beta_{\mathcal{A}})_i \in \tau \ \forall i$, then $\sqcup_{i\in J} (\beta_{\mathcal{A}})_i \in \tau$.

τ is called a topology of $fss's$ on $\mathcal{U}$. Each member of τ is called an open fss. $\mathcal{S}_{\mathcal{B}}$ is called a closed fss in $(\mathcal{U}, \tau, S)$ if $\mathcal{S}_{\mathcal{B}}^c \in \tau$.

Definition 2.8 [14] A quadruple $(\mathcal{U}, \tau_1, \tau_2, S)$ is called fuzzy soft bitopological space where τ_1, τ_2 are arbitrary fuzzy soft topologies on $\mathcal{U}$ with a fixed set of parameters S.

3. Čech Fuzzy Soft Bi-Closure Spaces

In this section, we introduce the concept of Čfs bi-csp and study its fundamental properties. For $i, j = 1,2$ where $i \neq j$.

Definition 3.1 A Čfs bi-csp is a quadruple $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ where $\mathcal{U}$ is a nonempty set and $\mathcal{L}_1, \mathcal{L}_2 : \mathcal{FS}(\mathcal{U}, S) \to \mathcal{FS}(\mathcal{U}, S)$ are two fuzzy soft closure operators on $\mathcal{U}$ which satisfy the following axioms:

(A_1) $\mathcal{L}_i(\tilde{0}_S) = \tilde{0}_S$,
(A_2) $\beta_{\mathcal{A}} \sqsubseteq \mathcal{L}_i(\beta_{\mathcal{A}})$ for all $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{U}, S)$,
(A_3) $\mathcal{L}_i(\beta_{\mathcal{A}} \cup \mathcal{S}_{\mathcal{B}}) = \mathcal{L}_i(\beta_{\mathcal{A}}) \sqcup \mathcal{L}_i(\mathcal{S}_{\mathcal{B}})$ for all $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}} \in \mathcal{FS}(\mathcal{U}, S)$.

Definition 3.2 A $fss\ \beta_{\mathcal{A}}$ of a Čfs bi-csp $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is said to be $\mathcal{L}_i$-closed fss if $\mathcal{L}_i(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$. And, it is called a closed fss if and only if $\mathcal{L}_i(\mathcal{L}_j(\beta_{\mathcal{A}})) = \beta_{\mathcal{A}}$. The complement of a closed fss is called an open fss.

Proposition 3.3 Let $\beta_{\mathcal{A}}$ be a fss of a Čfs bi-csp $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. Then,

1. $\beta_{\mathcal{A}}$ is a closed fss in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ if and only if $\beta_{\mathcal{A}}$ is $\mathcal{L}_j$-closed fss.
2. If $\beta_{\mathcal{A}}$ is an open fss in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$, then $\mathcal{L}_i(\mathcal{L}_j(\beta_{\mathcal{A}}^c)) = \mathcal{L}_j(\mathcal{L}_i(\beta_{\mathcal{A}}^c))$.

Proof: The proof follows from Defenition 3.2.

The convers of statement 2 in Proposition 3.3, need not be in general as seen from the following example.

Example 3.4**.** Let $\mathcal{U} = \{x, y, z\}$, $S = \{s_1, s_2\}$ and $\mathcal{S}_{\mathcal{B}} \in \mathcal{FS}(\mathcal{U}, S)$,such that $\mathcal{S}_{\mathcal{B}} = \{(s_1, y_{0.6}), (s_2, y_{0.6})\}$. Define fuzzy soft closure operators $\mathcal{L}_1, \mathcal{L}_2 : \mathcal{FS}(\mathcal{U}, S) \to \mathcal{FS}(\mathcal{U}, S)$ as follows:

$$\mathcal{L}_1(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, x_{0.5} \vee y_{0.6}), (s_2, x_{0.5} \vee y_{0.6})\} & if\ \beta_{\mathcal{A}} \sqsubseteq \mathcal{S}_{\mathcal{B}}, \\ \tilde{1}_S & otherwise. \end{cases}$$

and

$$\mathcal{L}_2(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, y_{0.6} \vee z_{0.5}), (s_2, y_{0.6} \vee z_{0.5})\} & if\ \beta_{\mathcal{A}} \sqsubseteq \mathcal{S}_{\mathcal{B}}, \\ \tilde{1}_S & otherwise. \end{cases}$$

Then, it is clear that $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is a Čfs bi-csp. Consider $\beta_{\mathcal{A}} = \{(s_1, x_{0.7} \vee y_{0.2}), (s_2, x_{0.5} \vee z_{0.9})\}$. Then we can see that $\mathcal{L}_1(\mathcal{L}_2(\beta_{\mathcal{A}}^c)) = \mathcal{L}_2(\mathcal{L}_1(\beta_{\mathcal{A}}^c)) = \tilde{1}_S$ however $\beta_{\mathcal{A}}$ is not open fss in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$.

Proposition 3.5 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}} \in \mathcal{FS}(\mathcal{U}, S)$ such that $\beta_{\mathcal{A}} \sqsubseteq \mathcal{S}_{\mathcal{B}}$, then $\mathcal{L}_i\big(\mathcal{L}_j(\beta_{\mathcal{A}})\big) \sqsubseteq \mathcal{L}_i\big(\mathcal{L}_j(\mathcal{S}_{\mathcal{B}})\big)$.

Proof: It is clear that from Theorem 2.4 party 4 and of Definition 3.1 we have

$$\begin{aligned}\mathcal{L}_i\left(\mathcal{L}_j(\beta_{\mathcal{A}})\right) &\sqsubseteq \mathcal{L}_i\left(\mathcal{L}_j(\beta_{\mathcal{A}})\right) \sqcup \mathcal{L}_i\left(\mathcal{L}_j(\mathcal{S}_{\mathcal{B}})\right)\\ &= \mathcal{L}_i\left(\mathcal{L}_j(\beta_{\mathcal{A}}) \sqcup \mathcal{L}_j(\mathcal{S}_{\mathcal{B}})\right)\\ &= \mathcal{L}_i\left(\mathcal{L}_j(\beta_{\mathcal{A}} \sqcup \mathcal{S}_{\mathcal{B}})\right)\\ &= \mathcal{L}_i\big(\mathcal{L}_j(\mathcal{S}_{\mathcal{B}})\big).\end{aligned}$$

Proposition 3.6 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{U}, S)$. If $\mathcal{L}_i(\beta_{\mathcal{A}})$ is contained in $\beta_{\mathcal{A}}$, then $\beta_{\mathcal{A}}$ is a closed fss.

Proof: From hypotheses, axiom (A_2) in Definition 3.1 and statement 1 in Proposition 3.3, we can easily obtain the result.

Definition 3.7 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{U}, S)$. The fuzzy soft interior of $\beta_{\mathcal{A}}$, denoted by $Int_i\left(Int_j(\beta_{\mathcal{A}})\right)$ for the Čech fuzzy soft closure operators $\mathcal{L}_i$ and $\mathcal{L}_j$ is defined as $Int_i\left(Int_j(\beta_{\mathcal{A}})\right) = (\mathcal{L}_i(\mathcal{L}_j(\beta_{\mathcal{A}}^c))^c$.

It is clear that if $\beta_{\mathcal{A}}$ is an open fss, then $Int_i\left(Int_j(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$.

In the following proposition, we give the main properties of the fuzzy soft interior of a $fss's$.

Proposition 3.8 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}} \in \mathcal{FS}(\mathcal{U}, S)$. Then

1. $Int_i\left(Int_j(\tilde{0}_S)\right) = \tilde{0}_S$ and $Int_i\left(Int_j(\tilde{1}_S)\right) = \tilde{1}_S$.
2. $Int_i\left(Int_j(\beta_{\mathcal{A}})\right) \sqsubseteq \beta_{\mathcal{A}}$.
3. $Int_i\left(Int_j(\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}})\right) = Int_i\left(Int_j(\beta_{\mathcal{A}})\right) \sqcap Int_i\left(Int_j(\mathcal{S}_{\mathcal{B}})\right)$.
4. If $\beta_{\mathcal{A}} \sqsubseteq \mathcal{S}_{\mathcal{B}}$, then $Int_i\left(Int_j(\beta_{\mathcal{A}})\right) \sqsubseteq Int_i\left(Int_j(\mathcal{S}_{\mathcal{B}})\right)$.
5. $\beta_{\mathcal{A}}$ is open fss if and only if $Int_i\left(Int_j(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$.

Proof: Straight forward.

Next, we discuss the behavior of open $fss's$ in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ to know the types of fuzzy soft topologies that induced by any Čfs bi-csp.

Theorem 3.9 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp. Then,

1. The intersection of any members of closed $fss's$ in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is a closed fss over $\mathcal{U}$.
2. The union of any two members of closed $fss's$ in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is a closed fss over $\mathcal{U}$.

Proof:

1. Let $\{(\beta_{\mathcal{A}})_\alpha : \alpha \in \Lambda\}$ be an arbitrary collection of closed $fss's$ over $\mathcal{U}$. For each $\alpha \in \Lambda$, we have $\sqcap_{\alpha\in\Lambda}(\beta_{\mathcal{A}})_\alpha \sqsubseteq (\beta_{\mathcal{A}})_\alpha$. From Proposition 3.5 we get $\mathcal{L}_i(\mathcal{L}_j(\sqcap_{\alpha\in\Lambda}(\beta_{\mathcal{A}})_\alpha) \sqsubseteq \mathcal{L}_i(\mathcal{L}_j((\beta_{\mathcal{A}})_\alpha) =$

$(\beta_{\mathcal{A}})_{\alpha}$. This yields, $\mathcal{L}_i(\mathcal{L}_j(\sqcap_{\alpha\in\Lambda}(\beta_{\mathcal{A}})_{\alpha}) \sqsubseteq \sqcap_{\alpha\in\Lambda}(\beta_{\mathcal{A}})_{\alpha}$. The other hand follow from (A_2) of Definition 3.1.

2. Let $\beta_{\mathcal{A}}$ and $\mathcal{S}_{\mathcal{B}}$ be closed $fss's$ over $\mathcal{U}$. Then from Proposition 3.5, it follows $\mathcal{L}_i(\mathcal{L}_j(\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}}) \sqsubseteq \mathcal{L}_i\left(\mathcal{L}_j(\beta_{\mathcal{A}})\right) \sqcap \mathcal{L}_i\left(\mathcal{L}_j(\mathcal{S}_{\mathcal{B}})\right) = (\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}})$. Therefore, $\mathcal{L}_i(\mathcal{L}_j(\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}}) \sqsubseteq \beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}}$. The other hand follows from (A_2) of Definition 3.1.

Corollary 3.10 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp, Then,

1. The union of any collection of open $fss's$ in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is an open fss over $\mathcal{U}$.
2. The intersection of any two open $fss's$ in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is an open fss over $\mathcal{U}$.

Now, we can define the types of fuzzy soft topologies that associated from Čfs bi-csp.

Definition 3.11 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp. Then,

1. The associated fuzzy soft topologies $\tau_{\mathcal{L}_i}$on $\mathcal{U}$ is defined as $\tau_{\mathcal{L}_i} = \{\beta^c_{\mathcal{A}}: \mathcal{L}_i(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}\}$ is the family of all $\mathcal{L}_i$-open $fss's$ of $(\mathcal{U}, \mathcal{L}_i, S)$ [9]. Also, $(\mathcal{U}, \tau_{\mathcal{L}_1}, \tau_{\mathcal{L}_2}, S)$ is a fuzzy soft bitopological space.
2. The associated fuzzy soft topologies $\tau_{\mathcal{L}_i\mathcal{L}_j}$ is defined as $\tau_{\mathcal{L}_i\mathcal{L}_j} = \{\beta^c_{\mathcal{A}}: \mathcal{L}_i(\mathcal{L}_j(\beta_{\mathcal{A}})) = \beta_{\mathcal{A}}\}$ is the family of all open $fss's$ of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ and $(\mathcal{U}, \tau_{\mathcal{L}_i\mathcal{L}_j}, S)$ is a fuzzy soft topological space.

Clearly, from Definition 3.11, we have $\tau_{\mathcal{L}_i\mathcal{L}_j} = \tau_{\mathcal{L}_i} \cap \tau_{\mathcal{L}_j}$.

4. Čech fuzzy soft bi-closure subspaces

In this section, we introduce the concept of subspaces in Čfs bi-csp's and give some properties of it.

Theorem 4.1 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $\mathcal{V} \subseteq \mathcal{U}$. Let $\mathcal{L}_{i_\mathcal{V}}: \mathcal{FS}(\mathcal{V}, S) \to \mathcal{FS}(\mathcal{V}, S)$ defined by $\mathcal{L}_{i_\mathcal{V}}(\beta_{\mathcal{A}}) = \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_i(\beta_{\mathcal{A}})$ for all $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{V}, S)$. Then, $\mathcal{L}_{i_\mathcal{V}}$ is a fuzzy soft closure operator on $\mathcal{V}$.

Proof: We must prove $\mathcal{L}_{i_\mathcal{V}}$ satisfying the axioms $(\mathrm{A}_1) - (\mathrm{A}_3)$ in Definition 3.1.

(A_1) $\mathcal{L}_{i_\mathcal{V}}(\tilde{0}_S) = \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_i(\tilde{0}_S) = \tilde{\mathcal{V}}_S \sqcap \tilde{0}_S = \tilde{0}_S$.

(A_2) For any $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{V}, S), \beta_{\mathcal{A}} \sqsubseteq \tilde{\mathcal{V}}_S$ and $\beta_{\mathcal{A}} \sqsubseteq \mathcal{L}_i(\beta_{\mathcal{A}})$. This yields $\beta_{\mathcal{A}} \sqsubseteq \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_i(\beta_{\mathcal{A}}) = \mathcal{L}_{i_\mathcal{V}}(\beta_{\mathcal{A}})$. Hence, $\beta_{\mathcal{A}} \sqsubseteq \mathcal{L}_{i_\mathcal{V}}(\beta_{\mathcal{A}})$.

(A_3) Let $\beta_{\mathcal{A}}, \mathcal{S}_{\mathcal{B}} \in \mathcal{FS}(\mathcal{V}, S)$. Then

$$\begin{aligned}\mathcal{L}_{i_\mathcal{V}}(\beta_{\mathcal{A}} \sqcup \mathcal{S}_{\mathcal{B}}) &= \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_i(\beta_{\mathcal{A}} \sqcup \mathcal{S}_{\mathcal{B}}) \\ &= \tilde{\mathcal{V}}_S \sqcap \left(\mathcal{L}_i(\beta_{\mathcal{A}}) \sqcup \mathcal{L}_i(\mathcal{S}_{\mathcal{B}})\right) \\ &= \mathcal{L}_{i_\mathcal{V}}(\beta_{\mathcal{A}}) \sqcup \mathcal{L}_{i_\mathcal{V}}(\mathcal{S}_{\mathcal{B}}).\end{aligned}$$

Definition 4.2 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $\mathcal{V} \subseteq \mathcal{U}$. The fuzzy soft closure operator $\mathcal{L}_{i_\mathcal{V}}$ (that defined in Theorem 4.1) is called the relative fuzzy soft closure operator on $\mathcal{V}$ induced by $\mathcal{L}_i$. The quadruple $(\mathcal{V}, \mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}, S)$ is called a Čech fuzzy soft bi-closure subspace (Čfs bi-csubsp, for short) of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. The Čfs bi-csubsp $(\mathcal{V}, \mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}, S)$ is said to be a closed (resp. open) subspace if $\tilde{\mathcal{V}}_S$is a closed (resp. open) fss over $\mathcal{U}$.

Example 4.3 In Example 3.4, let $\mathcal{V} = \{x, z\} \subseteq \mathcal{U}$. Then $\mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}: \mathcal{FS}(\mathcal{V}, S) \to \mathcal{FS}(\mathcal{V}, S)$ defined as $\mathcal{L}_{1_\mathcal{V}}(\beta_{\mathcal{A}}) = \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_1(\beta_{\mathcal{A}})$ and $\mathcal{L}_{2_\mathcal{V}}(\beta_{\mathcal{A}}) = \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_2(\beta_{\mathcal{A}})$ as follows:

$$\mathcal{L}_{1_\mathcal{V}}(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, x_{0.9})\} & if\ \beta_{\mathcal{A}} \in \{(s_1, x_t); 0 < t \leq 0.9\}, \\ \tilde{\mathcal{V}}_S & otherwise. \end{cases}$$

$$\mathcal{L}_{2_\nu}(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, x_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, x_t); t \in I_0\}, \\ \{(s_2, z_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_2, z_k); k \in I_0\}, \\ \{\mathcal{L}_{2_\nu}(\{(s_1, x_t)\}), \mathcal{L}_{2_\nu}(\{(s_2, z_k)\})\} & if\ \beta_{\mathcal{A}} \in \{(s_1, x_t), (s_2, z_k); t, k \in I_0\} \\ \tilde{\mathcal{V}}_S & otherwise. \end{cases}$$

Then $(\mathcal{V}, \mathcal{L}_{1_\nu}, \mathcal{L}_{2_\nu}, S)$ is Čfs bi-csubsp of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$.

Definition 4.4 Let $(\mathcal{V}, \mathcal{L}_{1_\nu}, \mathcal{L}_{2_\nu}, S)$be a Čfs bi-csubsp of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. A $fss\ \beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{V}, S)$ is said to be closed fss over $\mathcal{V}$ if $\mathcal{L}_{i_\nu}(\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}})) = \beta_{\mathcal{A}}$.

Proposition 4.5 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $(\mathcal{V}, \mathcal{L}_{1_\nu}, \mathcal{L}_{2_\nu}, S)$ be a Čfs bi-csubsp of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. Let $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{V}, S)$. Then, $\beta_{\mathcal{A}}$ is a closed fss over $\mathcal{V}$ if and only if $\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$.

Proof**:** Suppose $\beta_{\mathcal{A}}$ is a closed over $(\mathcal{V}, \mathcal{L}_{1_\nu}, \mathcal{L}_{2_\nu}, S)$. From (A_2) of Theorem 4.1 we have, $\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}}) \sqsubseteq \mathcal{L}_{i_\nu}\left(\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$, and since $\beta_{\mathcal{A}} \sqsubseteq \mathcal{L}_{j_\nu}(\beta_{\mathcal{A}})$, then it follows $\beta_{\mathcal{A}} \sqsubseteq \mathcal{L}_{j_\nu}(\beta_{\mathcal{A}}) \sqsubseteq \mathcal{L}_{i_\nu}\left(\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$. Hence, $\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$.

Conversely, let $\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$, then $\mathcal{L}_{1_\nu}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$ and $\mathcal{L}_{2_\nu}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$ (since $j = 1,2$). Then, it follows, $\mathcal{L}_{2_\nu}\left(\mathcal{L}_{1_\nu}(\beta_{\mathcal{A}})\right) = \mathcal{L}_{2_\nu}(\beta_{\mathcal{A}})$ and $\mathcal{L}_{1_\nu}\left(\mathcal{L}_{2_\nu}(\beta_{\mathcal{A}})\right) = \mathcal{L}_{1_\nu}(\beta_{\mathcal{A}})$. This implies $\mathcal{L}_{2_\nu}\left(\mathcal{L}_{1_\nu}(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$ and $\mathcal{L}_{1_\nu}\left(\mathcal{L}_{2_\nu}(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$. Therefore, $\mathcal{L}_{i_\nu}\left(\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$. Consequently, $\beta_{\mathcal{A}}$ is a closed over $\mathcal{V}$.

Proposition 4.6 Let $(\mathcal{V}, \mathcal{L}_{1_\nu}, \mathcal{L}_{2_\nu}, S)$ be a Čfs bi-csubsp of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. If $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{V}, S)$ and $\beta_{\mathcal{A}}$ is a closed fss over $\mathcal{U}$, then $\beta_{\mathcal{A}}$ is a closed fss in $(\mathcal{V}, \mathcal{L}_{1_\nu}, \mathcal{L}_{2_\nu}, S)$.

Proof: Let $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{V}, S)$ and $\mathcal{L}_i\left(\mathcal{L}_j(\beta_{\mathcal{A}})\right) = \beta_{\mathcal{A}}$. Now,

$$\begin{aligned} \mathcal{L}_{i_\nu}\left(\mathcal{L}_{j_\nu}(\beta_{\mathcal{A}})\right) &= \mathcal{L}_{i_\nu}\left(\tilde{\mathcal{V}}_S \sqcap \mathcal{L}_j(\beta_{\mathcal{A}})\right) && \text{(By the definition of } \mathcal{L}_{j_\nu}) \\ &= \mathcal{L}_{i_\nu}(\tilde{\mathcal{V}}_S \sqcap \beta_{\mathcal{A}}) && \text{(Since } \beta_{\mathcal{A}} \text{ is closed over } \mathcal{U}) \\ &= \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_i(\tilde{\mathcal{V}}_S \sqcap \beta_{\mathcal{A}}) && \text{(By the definition of } \mathcal{L}_{i_\nu}) \\ &= \beta_{\mathcal{A}} \end{aligned}$$

Hence, $\beta_{\mathcal{A}}$ is a closed fss in $(\mathcal{V}, \mathcal{L}_{1_\nu}, \mathcal{L}_{2_\nu}, S)$.

The converse of Proposition 4.6 is not true as we explain in the next example.

Example 4.7 Let $\mathcal{U} = \{x, y, z, w\}$, $S = \{s_1, s_2\}$. Define fuzzy soft closure operators $\mathcal{L}_1, \mathcal{L}_2 : \mathcal{FS}(\mathcal{U}, S) \to \mathcal{FS}(\mathcal{U}, S)$ as follows*:*

$$\mathcal{L}_1(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, z_1), (s_2, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, z_{k_1}), (s_2, y_{h_1}); h_1, k_1 \in I_0\}, \\ \{(s_1, y_1), (s_2, z_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, y_{h_2}), (s_2, z_{k_2}); h_2, k_2 \in I_0\} \\ \{(s_1, y_1 \vee z_1), (s_2, y_1 \vee z_1)\} & if\ \beta_{\mathcal{A}} \in \left\{ \begin{matrix} (s_1, y_{h_1} \vee z_{k_1}), (s_2, y_{h_2} \vee z_{k_2}) \\ ; h_1, h_2, k_1, k_2 \in I_0 \end{matrix} \right\}, \\ \tilde{1}_S & otherwise. \end{cases}$$

$$\mathcal{L}_2(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, x_1), (s_2, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, x_{t_1}), (s_2, y_{h_1}); h_1, t_1 \in I_0\}, \\ \{(s_1, y_1), (s_2, x_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, y_{h_2}), (s_2, x_{t_2}); h_2, t_2 \in I_0\}, \\ \{(s_1, x_1 \vee y_1), (s_2, x_1 \vee y_1)\} & if\ \beta_{\mathcal{A}} \in \begin{Bmatrix} (s_1, x_{t_1} \vee y_{h_2}), (s_2, x_{t_2} \vee y_{h_1}) \\ ; t_1, t_2, h_1, h_2 \in I_0 \end{Bmatrix}, \\ \tilde{1}_S & otherwise. \end{cases}$$

Then $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is a Čfs bi-csp.

Let $\mathcal{V} = \{y, w\}$. Then $\mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}: \mathcal{FS}(\mathcal{V}, S) \to \mathcal{FS}(\mathcal{V}, S)$ defined as follows:

$$\mathcal{L}_{1_\mathcal{V}}(\beta_{\mathcal{A}}) = \mathcal{L}_{2_\mathcal{V}}(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_2, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_2, y_{h_1}); h_1 \in I_0\}, \\ \{(s_1, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, y_{h_2}); h_2 \in I_0\}, \\ \{(s_1, y_1), (s_2, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, y_{h_2}), (s_2, y_{h_1}); h_1, h_2 \in I_0\}, \\ \tilde{\mathcal{V}}_S & otherwise. \end{cases}$$

Then, $(\mathcal{V}, \mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}, S)$ is a Čfs bi-csubsp of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. Now, consider $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{V}, S)$ where $\beta_{\mathcal{A}} = \{(s_1, y_1)\}$. It is clear that $\beta_{\mathcal{A}}$ is a closed fss over $(\mathcal{V}, \mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}, S)$. Since $\mathcal{L}_{1_\mathcal{V}}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$ and $\mathcal{L}_{2_\mathcal{V}}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$ but $\beta_{\mathcal{A}}$ is not closed fss over $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ because $\mathcal{L}_1(\beta_{\mathcal{A}}) \neq \beta_{\mathcal{A}}$ or $\mathcal{L}_2(\beta_{\mathcal{A}}) \neq \beta_{\mathcal{A}}$. □

In the next, we study the condition to be the converse of Proposition 4.6 hold. First, we need to introduce the following lemma.

Lemma 4.8 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp and $\{(\beta_{\mathcal{A}})_\alpha : \alpha \in \Lambda\}$ be a family of $fss's$ over $\mathcal{U}$, then $\mathcal{L}_i(\sqcap_{\alpha\in\Lambda} (\beta_{\mathcal{A}})_\alpha) \sqsubseteq \sqcap_{\alpha\in\Lambda} \mathcal{L}_i((\beta_{\mathcal{A}})_\alpha)$.

Proof: For all $\alpha \in \Lambda$, since $\sqcap_{\alpha\in\Lambda} (\beta_{\mathcal{A}})_\alpha \sqsubseteq (\beta_{\mathcal{A}})_\alpha$. Then, $\mathcal{L}_i(\sqcap_{\alpha\in\Lambda} (\beta_{\mathcal{A}})_\alpha) \sqsubseteq \mathcal{L}_i((\beta_{\mathcal{A}})_\alpha)$ for all $\alpha \in \Lambda$. Therefore, $\mathcal{L}_i(\sqcap_{\alpha\in\Lambda} (\beta_{\mathcal{A}})_\alpha) \sqsubseteq \sqcap_{\alpha\in\Lambda} \mathcal{L}_i((\beta_{\mathcal{A}})_\alpha)$.

The converse of Lemma 4.8 is not true as we explain in the next example.

Example 4.9 Let $\mathcal{U} = \{x, y, z\}$, $S = \{s_1, s_2\}$ and let $\theta = \{(s_1, x_t \vee y_h), (s_2, z_k); t, h, k \in I_0\}$. Define fuzzy soft closure operators $\mathcal{L}_1, \mathcal{L}_2: \mathcal{FS}(\mathcal{U}, S) \to \mathcal{FS}(\mathcal{U}, S)$ *as follows:*

$$\mathcal{L}_1(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, x_{0.9} \vee y_{0.1})\} & if\ \beta_{\mathcal{A}} \sqsubseteq \{(s_1, x_{0.9} \vee y_{0.1})\}, \\ \tilde{1}_S & otherwise. \end{cases}$$

and

$$\mathcal{L}_2(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_1, x_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, x_t); t \in I_0\}, \\ \{(s_1, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_1, y_h); h \in I_0\} \\ \{(s_2, z_1)\} & if\ \beta_{\mathcal{A}} \in \{(s_2, z_k); k \in I_0\}, \\ \{\mathcal{L}_2(\{(s_1, x_t)\}) \cup \mathcal{L}_2(\{(s_1, y_h)\}), \mathcal{L}_2(\{(s_2, z_k)\})\} & if\ \beta_{\mathcal{A}} \in \theta \\ \tilde{1}_S & otherwise. \end{cases}$$

Then, it's clear that $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is a Čfs bi-csp. Consider $\beta_{\mathcal{A}} = \{(s_1, x_{0.2})\}$ and $\mathcal{S}_{\mathcal{B}} = \{(s_1, y_{0.2} \vee z_{0.2})\}$. Then $\mathcal{L}_2(\beta_{\mathcal{A}}) = \{(s_1, x_1)\}$, $\mathcal{L}_2(\mathcal{S}_{\mathcal{B}}) = \tilde{1}_S$, and $\mathcal{L}_2(\beta_{\mathcal{A}}) \sqcap \mathcal{L}_2(\mathcal{S}_{\mathcal{B}}) = \{(s_1, x_1)\}$. On the other hand, $\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}} = \tilde{0}_S$ and $\mathcal{L}_2(\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}}) = \tilde{0}_S$. Hence, it's clear that $\{(s_1, x_1)\} = \mathcal{L}_2(\beta_{\mathcal{A}}) \sqcap \mathcal{L}_2(\mathcal{S}_{\mathcal{B}}) \not\sqsubseteq \mathcal{L}_2(\beta_{\mathcal{A}} \sqcap \mathcal{S}_{\mathcal{B}}) = \tilde{0}_S$.

The converse of Proposition 4.6 can be held if the following condition exists.

Theorem 4.10 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ be a Čfs bi-csp, $(\mathcal{V}, \mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}, S)$ be a closed subspace of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$, and let $\beta_\mathcal{A} \in \mathcal{FS}(\mathcal{V}, S)$. If $\beta_\mathcal{A}$ is a closed fss of $(\mathcal{V}, \mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}, S)$, then $\beta_\mathcal{A}$ is a closed fss of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$.

Proof: Let $\beta_\mathcal{A}$ is a closed fss over $\left(\mathcal{V}, \mathcal{L}_{1_\mathcal{V}}, \mathcal{L}_{2_\mathcal{V}}, S\right)$. We must prove $\mathcal{L}_i\left(\mathcal{L}_j(\beta_\mathcal{A})\right) = \beta_\mathcal{A}$. Since $\beta_\mathcal{A}$ is a closed fss over $\mathcal{V}$, then $\mathcal{L}_{i_\mathcal{V}}\left(\mathcal{L}_{j_\mathcal{V}}(\beta_\mathcal{A})\right) = \beta_\mathcal{A}$. From ($A_2$) of Theorem 4.1, $\mathcal{L}_{j_\mathcal{V}}(\beta_\mathcal{A}) \sqsubseteq \mathcal{L}_{i_\mathcal{V}}\left(\mathcal{L}_{j_\mathcal{V}}(\beta_\mathcal{A})\right) = \beta_\mathcal{A}$. It follows from the definition of $\mathcal{L}_{j_\mathcal{V}}$, $\tilde{\mathcal{V}}_S \sqcap \mathcal{L}_j(\beta_\mathcal{A}) \sqsubseteq \mathcal{L}_{i_\mathcal{V}}\left(\mathcal{L}_{j_\mathcal{V}}(\beta_\mathcal{A})\right) = \beta_\mathcal{A}$. Since $\tilde{\mathcal{V}}_S$ is a closed fss in $\mathcal{U}$ and from Lemma 4.8, $\mathcal{L}_j\left(\tilde{\mathcal{V}}_S \sqcap \beta_\mathcal{A}\right) \sqsubseteq \mathcal{L}_j\left(\tilde{\mathcal{V}}_S\right) \sqcap \mathcal{L}_j(\beta_\mathcal{A}) \sqsubseteq \tilde{\mathcal{V}}_S \sqcap \mathcal{L}_j(\beta_\mathcal{A}) \sqsubseteq \mathcal{L}_{i_\mathcal{V}}\left(\mathcal{L}_{j_\mathcal{V}}(\beta_\mathcal{A})\right) = \beta_\mathcal{A}$. Thus, $\mathcal{L}_j(\beta_\mathcal{A}) \sqsubseteq \beta_\mathcal{A}$. On the other hand $\beta_\mathcal{A} \sqsubseteq \mathcal{L}_j(\beta_\mathcal{A})$. Hence, we get $\mathcal{L}_j(\beta_\mathcal{A}) = \beta_\mathcal{A}$ and from Proposition. 3.3 part (1), we get $\beta_\mathcal{A}$ is a closed fss in $\mathcal{U}$.

5. Pairwise Čech fuzzy soft Continuous Mappings

Definition 5.1 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ and $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ be two Čfs bi-csp's. A fuzzy soft mapping $f_{up}: (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ is called

1. Pairwise Čech fuzzy soft continuous ($P\check{C}$-*fs*-continuous, briefly) mapping, if $f_{up}(\mathcal{L}_i(\beta_\mathcal{A})) \sqsubseteq \mathcal{L}_i^*(f_{up}(\beta_\mathcal{A}))$, for every $fss\ \beta_\mathcal{A} \in \mathcal{FS}(\mathcal{U}, S)$.
2. Pairwise* Čech fuzzy soft continuous ($P^*\check{C}$-*fs*-continuous, briefly) mapping, if $f_{up}^{-1}(\mathcal{S}_\mathcal{B})$ is an open fss of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ for every open $fss\ \mathcal{S}_\mathcal{B}$ of $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$.

Theorem 5.2 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ and $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ be two Čfs bi-csp's. If $f_{up}: (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ is a $P\check{C}$-*fs*-continuous mapping if and only if $\mathcal{L}_i(f_{up}^{-1}(\mathcal{S}_\mathcal{B})) \sqsubseteq f_{up}^{-1}(\mathcal{L}_i^*(\mathcal{S}_\mathcal{B}))$, for every $fss\ \mathcal{S}_\mathcal{B} \in \mathcal{FS}(\mathcal{W}, \mathcal{N})$.

Proof: Let $\mathcal{S}_\mathcal{B} \in \mathcal{FS}(\mathcal{W}, \mathcal{N})$. Then, $f_{up}^{-1}(\mathcal{S}_\mathcal{B}) \in \mathcal{FS}(\mathcal{U}, S)$. Since f_{up} is $P\check{C}$-*fs*-continuous, we have $f_{up}(\mathcal{L}_i(f_{up}^{-1}(\mathcal{S}_\mathcal{B})) \sqsubseteq \mathcal{L}_i^*(f_{up}\left(f_{up}^{-1}(\mathcal{S}_\mathcal{B})\right) \sqsubseteq \mathcal{L}_i^*(\mathcal{S}_\mathcal{B})$. Therefore, $f_{up}^{-1}(f_{up}\left(\mathcal{L}_i\left(f_{up}^{-1}(\mathcal{S}_\mathcal{B})\right)\right)) \sqsubseteq f_{up}^{-1}\left(\mathcal{L}_i^*(\mathcal{S}_\mathcal{B})\right)$. Hence, $\mathcal{L}_i(f_{up}^{-1}(\mathcal{S}_\mathcal{B})) \sqsubseteq f_{up}^{-1}\left(\mathcal{L}_i^*(\mathcal{S}_\mathcal{B})\right)$.
Conversely, let $\beta_\mathcal{A}$ be a fss of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. From the definition of the image of fss and hypothesis we get $\mathcal{L}_i(f_{up}^{-1}(f_{up}((\beta_\mathcal{A})) \sqsubseteq f_{up}^{-1}(\mathcal{L}_i^*(f_{up}(\beta_\mathcal{A}))$. By taking the image we obtain the result.□
Theorem 5.3. Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ and $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ be two Čfs bi-csp's. If $f_{up}: (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ is a $P\check{C}$-*fs*-continuous mapping, then f_{up} is $P^*\check{C}$-*fs*-continuous mapping.

Proof: The proof is easy.

The converse of Theorem 5.3 need not be held as seen in the following next example.

Example 5.4 Let $\mathcal{U} = \{x, y\} = \mathcal{W}$, $S = \{s_1, s_2\}$ and $\mathcal{N} = \{k_1, k_2\}$ and $\Upsilon = \{\left(k_1, x_{t_1} \vee y_{r_1}\right), \left(k_2, x_{t_2} \vee y_{r_2}\right): t_1, t_2, r_1, r_2 \in I_0\}$.
Define fuzzy soft closure operator $\mathcal{L}_1, \mathcal{L}_2: \mathcal{FS}(\mathcal{U}, S) \to \mathcal{FS}(\mathcal{U}, S)$ *as follows:*

$$\mathcal{L}_1(\beta_\mathcal{A}) = \begin{cases} \tilde{0}_S & if\ \beta_\mathcal{A} = \tilde{0}_S, \\ \{(s_1, x_{0.3})\} & if\ \beta_\mathcal{A} \sqsubseteq \{(s_1, x_{0.2})\}, \\ \tilde{1}_S & otherwise. \end{cases}$$

and

$$\mathcal{L}_2(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_S & if\ \beta_{\mathcal{A}} = \tilde{0}_S, \\ \{(s_2, x_{0.3} \vee y_{0.4})\} & if\ \beta_{\mathcal{A}} \sqsubseteq \{(s_2, x_{0.3} \vee y_{0.4})\}, \\ \tilde{1}_S & otherwise. \end{cases}$$

Define fuzzy soft closure operator $\mathcal{L}_1^*, \mathcal{L}_2^* : \mathcal{FS}(\mathcal{W}, \mathcal{N}) \to \mathcal{FS}(\mathcal{W}, \mathcal{N})$ as follows:

$$\mathcal{L}_1^*(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_{\mathcal{N}} & if\ \beta_{\mathcal{A}} = \tilde{0}_{\mathcal{N}}, \\ \{(k_1, x_1)\} & if\ \beta_{\mathcal{A}} \in \{(k_1, x_{t_1}) : t_1 \in I_0\}, \\ \{(k_2, x_1)\} & if\ \beta_{\mathcal{A}} \in \{(k_2, x_{t_2}) : t_2 \in I_0\}, \\ \{(k_1, y_{r_1+0.2})\} & if\ \beta_{\mathcal{A}} \in \{(k_1, y_{r_1}) : 0 < r_1 < 0.8\}, \\ \{(k_1, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(k_1, y_{r_1}) : 0.8 \le r_1 \le 1\}, \\ \{(k_2, y_1)\} & if\ \beta_{\mathcal{A}} \in \{(k_2, y_{r_2}) : r_2 \in I_0\}, \\ \mathcal{L}_1^*(\{(k_1, x_{t_1})\}) \cup \mathcal{L}_1^*(\{(k_1, y_{r_1})\}) \cup & \\ \mathcal{L}_1^*(\{(k_2, x_{t_2})\}) \cup \mathcal{L}_1^*(\{(k_2, y_{r_2})\}) & if\ \beta_{\mathcal{A}} \in \Upsilon. \end{cases}$$

and

$$\mathcal{L}_2^*(\beta_{\mathcal{A}}) = \begin{cases} \tilde{0}_{\mathcal{N}} & if\ \beta_{\mathcal{A}} = \tilde{0}_{\mathcal{N}}, \\ \tilde{1}_{\mathcal{N}} & otherwise. \end{cases}$$

Define $f_{up} : (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ be the fuzzy soft identity mapping. Then, $f_{up}^{-1}(\mathcal{S}_{\mathcal{B}})$ ia an open fss of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ for every open fss $\mathcal{S}_{\mathcal{B}}$ *of* $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ but there exists $\beta_{\mathcal{A}} = \{(s_1, x_{0.5})\}$ be fss in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ such that $f_{up}(\mathcal{L}_1(\beta_{\mathcal{A}})) = \tilde{1}_S \not\subseteq \{(s_1, x_1)\} = \mathcal{L}_1^*\left(f_{up}(\beta_{\mathcal{A}})\right)$. Hence, f_{up} is not $P\check{C}$-*fs*-continuous mapping.

Theorem 5.5 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S), (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ and $(\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$ be Čfs bi-csp's. If $f_{up} : (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ and $h_{vj} : (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N}) \to (\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$ are $P\check{C}$-*fs*-continuous mappings, then $h_{vj} \circ f_{up} : (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$ is a $P\check{C}$-*fs*-continuous mapping.

Proof: Let $\beta_{\mathcal{A}} \in \mathcal{FS}(\mathcal{U}, S)$. Since $h_{vj} \circ f_{up}(\mathcal{L}_i(\beta_{\mathcal{A}})) = h_{vj}(f_{up}(\mathcal{L}_i(\beta_{\mathcal{A}})))$ and f_{up} is $P\check{C}$-*fs*-continuous, then $h_{vj}\left(f_{up}(\mathcal{L}_i(\beta_{\mathcal{A}}))\right) \sqsubseteq h_{vj}\left(\mathcal{L}_i^*\left(f_{up}(\beta_{\mathcal{A}})\right)\right)$. As h_{vj} is a $P\check{C}$-*fs*-continuous mapping, we get, $h_{vj}\left(\mathcal{L}_i^*\left(f_{up}(\beta_{\mathcal{A}})\right)\right) \sqsubseteq \mathcal{L}_i^{**}(h_{vj}\left(f_{up}(\beta_{\mathcal{A}})\right))$.

Consequently, $h_{vj}\left(f_{up}(\mathcal{L}_i(\beta_{\mathcal{A}}))\right) \sqsubseteq \mathcal{L}_i^{**}\left(h_{vj}(f_{up}(\beta_{\mathcal{A}})\right)$. That is mean $h_{vj} \circ f_{up}(\mathcal{L}_i(\beta_{\mathcal{A}})) \sqsubseteq \mathcal{L}_i^{**}\left(h_{vj} \circ f_{up}(\beta_{\mathcal{A}})\right)$. Hence $h_{vj} \circ f_{up}$ is a $P\check{C}$-*fs*-continuous mapping.

Definition 5.6 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S), (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ be Čfs bi-csp's. A fuzzy soft mapping $f_{up} : (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ is called

1. Pairwise Čech fuzzy soft open (resp. closed) mapping ($P\check{C}$-*fs*-open (resp. $P\check{C}$-*fs*-closed), briefly) mapping, if $f_{up}(\beta_{\mathcal{A}})$ is a $\mathcal{L}_i^*$-open (resp. closed) fss of $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$, whenver $\beta_{\mathcal{A}}$ is a $\mathcal{L}_i$-open (resp. closed) fss of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$.
2. Pairwise* Čech fuzzy soft open (resp. closed) mapping ($P^*\check{C}$-*fs*-open (resp. $P^*\check{C}$-*fs*-closed), briefly) mapping, if the image of every open (resp. closed) fss in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ is an open (resp. closed) fss of in $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$.

Proposition 5.7 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ and $(\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ be two Čfs bi-csp's. If $f_{up} : (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^*, \mathcal{L}_2^*, \mathcal{N})$ is a $P\check{C}$-*fs*-open (resp. closed) mapping, then f_{up} is $P^*\check{C}$-*fs*-open (resp. closed) mapping.
Proof: Follows directly from Definition 5.1.

The converse of Proposition 5.7 need not be held, in Example 5.4 f_{up} is $P^{*}\check{C}$-*fs*-open mapping but it is not $P\check{C}$-*fs*-open mapping because there exists $\beta_{\mathcal{A}} = \{(s_1, x_1 \vee y_1), (s_2, x_{0.7} \vee y_{0.6})\}$ is $\mathcal{L}_2$-open fss in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$ but $f_{up}(\beta_{\mathcal{A}}) = \beta_{\mathcal{A}}$ is not $\mathcal{L}_2^{*}$-open fss in $(\mathcal{W}, \mathcal{L}_1^{*}, \mathcal{L}_2^{*}, \mathcal{N})$.

Theorem 5.8 Let $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S), (\mathcal{W}, \mathcal{L}_1^{*}, \mathcal{L}_2^{*}, \mathcal{N})$ and $(\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$ be Čfs bi-csp's. Let $f_{up}: (\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S) \to (\mathcal{W}, \mathcal{L}_1^{*}, \mathcal{L}_2^{*}, \mathcal{N})$ and $h_{vj}: (\mathcal{W}, \mathcal{L}_1^{*}, \mathcal{L}_2^{*}, \mathcal{N}) \to (\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$ fuzzy soft mappings. Then

1. If f_{up} and h_{vj} are $P\check{C}$-*fs*-closed mapping, then $h_{vj} \circ f_{up}$ is $P\check{C}$-*fs*-closed mapping.
2. If $h_{vj} \circ f_{up}$ is $P\check{C}$-*fs*-closed mapping and f_{up} is $P\check{C}$-*fs*-continuous and surjection, then h_{vj} is PČ-fs-closed mapping.
3. If $h_{vj} \circ f_{up}$ is $P\check{C}$-*fs*-closed mapping and h_{vj} is $P\check{C}$-*fs*-continuous and injection, then f_{up} is $P\check{C}$-*fs*-closed mapping.

Proof:

1. Let $\beta_{\mathcal{A}}$ be a $\mathcal{L}_i$-closed fss of $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. Since f_{up} is $P\check{C}$-*fs*-closed mapping, then $f_{up}(\beta_{\mathcal{A}})$ is $\mathcal{L}_i^{*}$-closed fss in $(\mathcal{W}, \mathcal{L}_1^{*}, \mathcal{L}_2^{*}, \mathcal{N})$. Again, since, h_{vj} is $P\check{C}$-*fs*-closed mapping, then $h_{vj}(f_{up}(\beta_{\mathcal{A}}))$ is $\mathcal{L}_i^{**}$-closed fss in $(\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$. Hence, $h_{vj} \circ f_{up}$ is $P\check{C}$-*fs*-closed mapping.
2. Let $\beta_{\mathcal{A}}$ be a $\mathcal{L}_i^{*}$-closed fss of $(\mathcal{W}, \mathcal{L}_1^{*}, \mathcal{L}_2^{*}, \mathcal{N})$. Since f_{up} is $P\check{C}$-*fs*-continuous mapping, then $f_{up}^{-1}(\beta_{\mathcal{A}})$ is $\mathcal{L}_i$-closed fss in $(\mathcal{U}, \mathcal{L}_1, \mathcal{L}_2, S)$. Again, since $h_{vj} \circ f_{up}$ is $P\check{C}$-*fs*-closed mapping, then $h_{vj} \circ f_{up}\left(f_{up}^{-1}(\beta_{\mathcal{A}})\right) = h_{vj}(f_{up}(f_{up}^{-1}(\beta_{\mathcal{A}})))$ is $\mathcal{L}_i^{**}$-closed fss in $(\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$. But f_{up} is surjection, so that $h_{vj} \circ f_{up}\left(f_{up}^{-1}(\beta_{\mathcal{A}})\right) = h_{vj}\left(f_{up}\left(f_{up}^{-1}(\beta_{\mathcal{A}})\right)\right) = h_{vj}(\beta_{\mathcal{A}})$. Consequently, $h_{vj}(\beta_{\mathcal{A}})$ is a $\mathcal{L}_i^{**}$-closed fss in $(\mathcal{Z}, \mathcal{L}_1^{**}, \mathcal{L}_2^{**}, \mathcal{H})$. Therefore, h_{vj} is PČ-fs-closed mapping.
3. The proof is identical to part 2.

Classifications of subsets in the finite projective line

Classifications of subsets in the finite projective line

Najm Abdulzahra Makhrib Al-Seraji and Fatima Ahmed Musa

Department of Mathematics ,college of science, Mustansiriyah University, Baghdad, Iraq

E-mail: fatimaahmed48585@gmail.com

Abstract. The main purpose of this paper is to classify k-sets in projective line$PG(1,29)$ which are a set of k projective distinct points. The projective line has been classified into$k$-set,$k = 3,4,\dots,10$,equivalent and inequivalent. Also, the projective equation of the k-sets and the stabilizer groups of them are constructed. All the computations are doing by using the Group's algorithm language GAP[7].

1. Introduction

Thethemeof projective line over the finite field F_q , $PG(1,q)$ has been studied by many mathematicians. The ideas and definitions of this research are taken from Hirshfeld [1].In 2013Al-Seraji and Hirschfeld[2] studied the geometry of the line of order seventeen.1n 2014 Al-Seraji [3] has been classified the projective line over the Galois field of order sixteen. In 2016 Al-Zangana [4] has been shown the classification of the projective line of order nineteen. In 2015 Al-Seraji [5] has been described the classification of the projective line over Galois field of order 23. In 2018 Al-Zangana and shehab [6]have been studied the classification of k-sets in $PG(1,25)$.

The 30 points of $PG(1,29)$ are $[x_0, x_1]$,$x_i \in \mathbb{F}_{29}$ .So
$PG(1,29) = \{U_0 = [1,0]\} \cup \{[x,1] | x \in \mathbb{F}_{29}\}$.The $[x_0, x_1]$ where $x_1 \neq 0$ is determined x_0 / x_1 . Thus
$PG(1,29) = \{[t,1] \mid t \in \mathbb{F}_{29} \cup \{\infty\}\}$

A projectivity$M(T)$ of $PG(1,29)$is $Y = XT$,where$X = (x_1, x_2)$, $Y = (y_1, y_2)$and T = $\begin{pmatrix} a' & b' \\ c' & d' \end{pmatrix}$. If put s = y_1 / y_2 and t = x_1 / x_2 ; then the projectivity can be written as an equation
s = $(a't + c') / (b't + d')$
Now we introduce the definitions which are using in this paper as follows:

Definition 1.1[1]: A k-set in the projective line $PG(1,q)$ is a set of k projectively distinct points.

Definition 1.2 [9]: A group G acts on a set Λ if there is a map $\Lambda \times G \to \Lambda$ such that given g ,g′ elements in G and 1 its identity , then
1. $y1 = y$,
2. $(yg)g' = y(gg')$ for any y in Λ.

Definition 1.3 [3]: The orbit of y in Λ under the action of G is the set
$yG = \{yg \mid g \in G\}$
Definition 1.4 [3]:The stabilizer of y in Λ under the action of G is the group
$G_y = \{g \in G \mid yg = y\}$

Theorem 1.5 [8]: There is a unique projectivity of $PG(1,q)$ transformation any three points to any three points.
For more details see [10], [11], [12], [13]

2.The Projective Line *PG*(1,29)

On $PG(1,29)$, the projective line over Galois field of order 29, there are 30 points. The points of $PG(1,29)$ are elements of the set

$$\mathbb{F}_{29} \cup \{\infty\} = \{\infty, 0, \pm1, \pm2, \pm3, \pm4, \pm5, \pm6, \pm7, \pm8, \pm9, \pm10, \pm11, \pm12, \pm13, \pm14\}.$$

The order of the projective group $PGL(2,29)$ is 30×29×28=24360. That is the number of three–point ordered sets. The polynomial function of degree two, $g(x) = x^2 + x + 3$ is a primitive over $\mathbb{F}29$, when $\mathbb{F}29 = \{1,2,\cdots,28; 29 = 0\}$. On $PG(1,29)$ there are 30 points. They are generated by a non-singular matrix of size 2×2; $S = C(g) = \begin{pmatrix} 0 & 1 \\ -3 & -1 \end{pmatrix}$. Such $P(j) = (1,0)\, S^j$, $j = 0,\cdots,29$. The points of $PG(1,29)$ are given in Table 1:

Table 1: The Points of (1,29)

$P(0) = [1,0]$	$P(1) = [0,1]$	$P(2) = [3,1]$
$P(3) = [13,1]$	$P(4) = [7,1]$	$P(5) = [14,1]$
$P(6) = [2,1]$	$P(7) = [26,1]$	$P(8) = [8,1]$
$P(9) = [12,1]$	$P(10) = [5,1]$	$P(11) = [21,1]$
$P(12) = [10,1]$	$P(13) = [19,1]$	$P(14) = [24,1]$
$P(15) = [15,1]$	$P(16) = [6,1]$	$P(17) = [11,1]$
$P(18) = [20,1]$	$P(19) = [9,1]$	$P(20) = [25,1]$
$P(21) = [18,1]$	$P(22) = [22,1]$	$P(23) = [4,1]$
$P(24) = [28,1]$	$P(25) = [16,1]$	$P(26) = [23,1]$
$P(27) = [17,1]$	$P(28) = [27,1]$	$P(29) = [1,1]$

The group action of $< S >$ on $PG\ (1,29)$is given as follows:

$$P(0) \xrightarrow{S} P(1) \xrightarrow{S} \ldots \xrightarrow{S} P(29) \xrightarrow{S} P(0)$$

So S cycles 30 points in $PG(1,29)$.

2.1 The 3-sets

Let T be the set of all different 3-sets in $PG(1,29)$. Then the order of T is |T|=30×29×28 =24360, Let $B = \{\infty, 0,1\}$be a 3-set which is one of them. By computing the transformations between B and all the other 3-set, we note that any 3-set is projectively equivalent to B.

Theorem 2.1.1: On $PG(1,29)$ there is accurately one 3-set.

Proof: On $PG(1,29)$, the number of the 3-set is 30×29×28 =24360. According to the Fundamental Theorem of Projective Geometry, Theorem(1.5).Take $\infty = [1,0]$, $0 = [0,1], 1 = [1,1]$ in $PG(1,29)$, so we have $\{\infty, 0,1\}$ is equivalent to any 3-set . The stabilizer group of $\{\infty, 0,1\}$ is give in Table 2.

Table 2: The 3-set on PG(1,29)

Symbol	The 3-set	stabilizer
B	$\{\infty, 0,1\}$	$S_3 = \langle \frac{28}{x+28}, 28x+1 \rangle$

Where $S_3 = \{x, 28x+1, \frac{1}{x}, \frac{28}{x+28}, \frac{28x+1}{28x}, \frac{x}{x+28}\}$

2.2 The 4-sets

The 4-set in $PG(1,29)$, is given by adding one point from each orbit that getsby the action of the projective group of the 3-set $G_B$on the complement of B. All orbits of the 3-set in Table 2 are given in Table 3.

Table 3: Partition of PG$(1,29)$ by the projectivities of 3-set

B	Partition of B^c
$\{\infty, 0,1\}$	1. $\{2,15,28\}$
	2. $\{3,10,14,16,20,27\}$
	3. $\{4,8,11,,19,22,26\}$
	4. $\{5,6,7,23,24,25\}$
	5. $\{9,12,13,17,18,21\}$

The total number of all orbits are5 and hence 5 inequivalent 4-sets can be formed in $PG(1.29)$.Table 3 gives the following conclusion.

Theorem 2.2.1: On $PG(1,29)$, there are accuratelyfive 4-sets, given their stabilizer group inTable 4.

Table- 4: Inequivalent 4-sets on PG(1,29)

Symbol	The 4-set	Stabilizer
B_1	$B \cup \{2\}$	$D_4 = \langle \frac{27}{x+27}, 28+2 \rangle$

B_2	$B \cup \{3\}$	$Z_2 \times Z_2 = \langle \frac{26}{28x} \rangle \times \langle \frac{x+26}{x+28} \rangle$
B_3	$B \cup \{4\}$	$Z_2 \times Z_2 = \langle \frac{25}{28x} \rangle \times \langle \frac{x+25}{x+28} \rangle$
B_4	$B \cup \{5\}$	$Z_2 \times Z_2 = \langle \frac{24}{28x} \rangle \times \langle \frac{x+24}{x+28} \rangle$
B_5	$B \cup \{9\}$	$Z_2 \times Z_2 = \langle \frac{20}{28x} \rangle \times \langle \frac{x+20}{x+28} \rangle$

Where $G(B_1) \cong D_4 = \langle \frac{27}{x+27}, 28x+2 \rangle$

$$= \{x, 28x+2, \frac{27}{28x}, \frac{27}{x+27}, \frac{x}{x+28}, \frac{x+27}{x+28}, \frac{27x+2}{28x}, \frac{27x+2}{28x+2}\}$$

$$G(B_2) \cong Z_2 \times Z_2 = \langle \frac{26}{28x}, \frac{x+26}{x+28} \rangle = \left\{x, \frac{26}{28x}, \frac{x+26}{x+28}, \frac{26x+3}{28x+3}\right\}$$

$$G(B_3) \cong Z_2 \times Z_2 = \langle \frac{25}{28x}, \frac{x+25}{x+28} \rangle = \left\{x, \frac{25}{28x}, \frac{x+25}{x+28}, \frac{25x+4}{28x+4}\right\}$$

$$G(B_4) \cong Z_2 \times Z_2 = \langle \frac{24}{28x}, \frac{x+24}{x+28} \rangle = \left\{x, \frac{24}{28x}, \frac{x+24}{x+28}, \frac{24x+5}{28x+5}\right\}$$

$$G(B_5) \cong Z_2 \times Z_2 = \langle \frac{20}{28x}, \frac{x+20}{x+28} \rangle = \left\{x, \frac{20}{28x}, \frac{x+20}{x+28}, \frac{20x+9}{28x+9}\right\}$$

The proof comes from above statements.

2.3 The 5-sets

The 5 projectivities of the $G_{B_i}, i = 1,2,3,4,5$ split ${B_i}^c$ into a number of orbits .The5-sets are constructed by adding one pointfrom each orbit to the corresponding 4-sets.All orbits are listed in Table 5.

Table 5 : Partition of PG(1,29) by the Projectivitiesof 4 -sets

B_i	Partition B_{i^c}
B_1	$\{3,4,11,15,16,20,27,28\}, \{5,8,9,12,19,22,23,26\}, \{6,7,10,14,17,21,24,25\}, \{13,18\}$
B_2	$\{2,16,26,28\}, \{4,8,9,10\}, \{5,6,15,16\}, \{7,17,19,20\}, \{11,24\}, \{12,14,22,23\}\{13,21,25,27\}$
B_3	$\{2,27\}, \{3,11,14,21\}, \{5,16,22,24\}, \{6,10,12,20\}, \{7,8,13,15\}, \{9,18,23,26\}, \{17,19,25,28\}$
B_4	$\{2,8,17,26\}, \{3,21,24,28\}, \{4,14,19,23\}, \{6,25\}, \{7,9,10,15\}, \{11,18\}, \{12,27\}, \{13,16,20,22\}$
B_5	$\{2,7,19,22\}, \{3,26\}, \{4,8,12,24\}, \{5,20,25,28\}, \{6,11,14,16\}, \{10,13,23,27\}\{15,17,18,21\}$

The total number of all orbits are33; and hence 33 5-sets can be formed in $PG(1,29)$.All equivalent 5-sets with their projective equations are listed in Table 6.

Table 6: The equivalence of 5 -sets

No.	Equivalent 5-sets	Projective equation
1	$B_1 \cup \{3\} \to B_2 \cup \{2\}$	x

Restrained Whole Domination in Graphs

Restrained Whole Domination in Graphs

Abstract. In this paper, we introduce a new definition of domination number in graphs called restrained whole domination number and denoted by$\gamma_{rwh}(G)$.Some bounds and results for restrained whole domination number are established. Moreover, this number is computed to the complement of certain graphs. Finally, the Effective the deletion or addition an edge or the deletion of a vertex of the graph has this number is discussed.

1. Introduction

We consider a graph $G = (V, E)$ for simplicity G as finite, simple and undirected. In recent years many fields of graph theory in mathematics are appears to solve many problems in as labeled graph [1],[2] and [3], topological graph [10], fuzzy graph [16], and others Claude Berge in 1962introduced concept of domination in graphs [5], after this time many parameters of domination are discussed as [4], [8], [11] and [12]. The set D in a graph G is a restrained dominating if each vertex in $V-D$is adjacent to at least one vertex in the set D and in the set$V-D$. The minimum cardinality of all these sets is called the restrained domination number of G denoted by γ_r (G). The concept of restrained domination is studied and investigated in [6], [7], [14] and [15]. Ibrahim is introduced the parameter whole domination number in his thesis [9]. For more details for the concepts used in this work, the reader can be found in [7] and [13].

Definition 1.1.[9]Let a graph G be a simple and connected, a proper subset $D \subset V$ is called whole dominating set (WDS), if every vertex in the set $V - D$ is adjacent to all vertices in the set D. The set D is called minimal WDS(MWDS) if it has no proper WDS. The whole domination number denoted by $\gamma_{wh}(G)$ for simplicity γ_{wh} is the minimum cardinality of a MWDS. The MWDS has γ_{wh} is called γ_{wh}-set.

Observation 1.2.[9]
i)$\gamma_{wh}(P_n) = 1$ *if* $2 \le n \le 3$, *otherwise* P_n *has no WDS.*
ii)$\gamma_{wh}(C_n) = \begin{Bmatrix}1, if n = 3\\ 2, if n = 4\end{Bmatrix}$, *otherwise* C_n *has no WDS.*
iii)$\gamma_{wh}(K_n) = \gamma_{wh}(W_n) = 1.$
iv)$\gamma_{wh}(K_{m,n}) = min\{m, n\}.$

Remark 1.3.[9]
If Gis a disconnected graph, then G has no WDS.

2.Restrained Whole Domination Number
Throughout this section a new definition of dominating set is initiated which is called an upper whole dominating set with study some of properties.

Definition 2.1. A WDS D⊂V is Restrained whole dominating set (RWDS), if each vertex in V– D is adjacent to at least one vertex in the set D and in the set V– D.

Definition 2.2. The restrained whole domination number of G denoted byγ_{rwh}(G), is the smallest cardinality of a SWDS of G.

Example 2.3. In the following Figure:

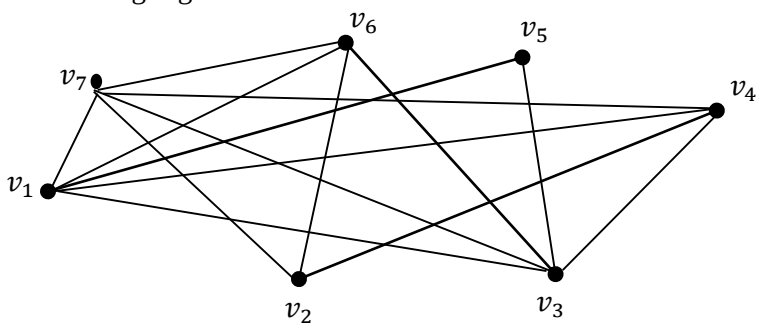

Figure 1

D= {v_1, v_2, v_3 } is minimum whole dominating set of G, thus, $\gamma_{wh}(G)$ = 3
D_1= {v_4, v_6, v_7 } is minimum restrained whole dominating set of G, $\gamma_{rwh}(G)$ = 3

Observation 2.4. If G is a graph and D is a RWDS with minimum cardinality.
1) If G has an isolated vertex, then G has no RWDS.
2)$\langle V - D\rangle$has no an isolated vertex.
3)$deg(v) \geq \gamma_{rwh}(G) + 1, \forall\, v \in V - D.$
4) $|V - D| \geq 2.$
5) $\gamma(G) \leq \gamma_{wh}(G) \leq \gamma_{rwh}(G).$

Theorem 2.5.
1) $\gamma_{rwh}(K_n) = 1$, *for any* n , $n \geq 3$.
2)$\gamma_{rwh}(C_n) = 1\ if\ n = 3$, *otherwise* C_n *has no RWDS.*
3)$\gamma_{rwh}(W_n) = 1$, *for any* n.
4)$\gamma_{rwh}(P_n)$has no RWDS in graph.
5)$\gamma_{\mathrm{rwh}}(\mathrm{K_{m,n}})$has no RWDS in graph.

Proof.
1) Let $D = \{v_i\}, i = 1,2, \dots, n$, it is clear that the set D is minimum RWDS and each vertex in $V - D$ is adjacent to the other vertex in $V - D$, since $n \geq 3$. Thus, the result is obtained.
2) If $n = 3$, then $C_3 = K_3$, and $\gamma_{rwh}(C_3) = 1$ by (1). If $\neq 3$, then the $\Delta(G) = 2$, so the maximum cardinality of neighborhood for each vertex (say v) in this graph is two say $\{w_1, w_2\}$. Now, if the set d

contains the vertex v, then the set V−d contain $\{w_1, w_2\}$. Since $n \neq 3$, so there is at least one other vertex say w_3, if this vertex belong to the set $V - D$, then the vertex v must adjacent to it according to the definition 2.1. and this is a contradiction with $\Delta(G) = 2$. In other hand, if w_3 belong to the set D, then again this vertex must adjacent to the two vertices $w_1, and w_2$ and this a contradiction with property of cycle since the vertex v is adjacent to these vertices. Thus, every cycle of order four or more has no RWDS.
3) Let $D = \{v\}$, where v is the center of the wheel graph, it is clear that the set D is minimum RWDS and each vertex in $V - D$ is adjacent to the other vertex in $V - D$, since $n \geq 3$. Thus, the result is obtained.
4) It is clear that P_n has WDS only when $n = 2,3$ by observation 1.2 (1), but in each cases the set $V - D$ contains an isolated vertex. Thus, the graph has no RWDS, according to observation 2.6 (1).
5) By observation 1.2 (iv) the set of WDS contains all vertices of partite of minimum cardinality. Thus, the set $V - D$ contains an isolated vertex, therefore the graph has no RWDS, according to observation 2.4 (1).

Note 2.6. The star graph $S_n \equiv K_{1,n-1}$ has no RWDS.

Proposition 2.7. If a graph G has WDS, then G has restrained whole dominating set if and only if G[V− D] has no isolated vertex.

Proof. It is straightforward from observation 1.2.□

Corollary 2.8. If G is a tree, then G has no RWDS.

Proof. Since G has no cycle, then all vertices in $V-D$is not adjacent.
So, $V-D$ are independent and G has no RWDS. □

Proposition 2.9. Let a graph G has RWDS. If D has no isolated in G[D], then V− DhasRWDSinG.

Proof. Let D be a minimum RWDS, the each vertex is adjacent to all vertices in $\langle V - D \rangle$. In other hand, each vertex in $V - D$ is also adjacent to all vertices in D. Furthermore, $\langle D \rangle$. has no an isolated vertex, thus $V-D$ hasRWDS in G. □

3.Complement the certain graphs
Theorem 3.1. If $G \equiv \overline{P_n}$then $\gamma_{rwh}(\overline{P_n}) = 2, \forall n > 5$*othewise* $\overline{P_n}$ *has no RWDS.*

Proof. There are four cases depend on n as follows.
Case 1. If $n \leq 3$, then $\overline{P_n}$ has an isolated vertex. Therefore, $\overline{P_n}$ has no RWDS, by Observation 2.4(1).
Case 2. If $n = 4$, then $\overline{P_4} \equiv P_4$ so again it has no RWDS, by Observation 2.4(1).
Case 3. If $n = 5$, then let $\{v_1, v_2, v_3, v_4, v_5\}$ the set of vertices of the graph $\overline{P_5}$. It is clear that the set $\{v_1, v_5\}$ is the only whole dominating set in $\overline{P_5}$, but this is not restrained, since the vertex v_3 is an isolated in $V - D$. Therefore, $\overline{P_5}$ has no RWDSaccording to Observation 2.5(1).
Case 4. If $n \geq 6$, the set $\{v_1, v_n\}$ is a minimum WDS and the set $V - D$has no an isolated vertex. Thus, $\gamma_{rwh}(P_n) = 2$.
From all cases above, the result is obtained. □
Theorem 3.2. If $G \equiv \overline{C_n}$, then $\gamma_{rwh}(\overline{C_n}) = 2, \forall n > 5$ othewise $\overline{C_n}$ has no RWDS.

Proof. There are three cases depend on n as follows.
Case 1. If $n \leq 4$, then $\overline{C_n}$is disconnected graph. Therefore, $\overline{C_n}$ has no WDS according to Remark 1.3. Thus, $\overline{C_n}$ has no restrained whole.

Case 2. If $n = 5$, then $\overline{C_5} \equiv C_5$ so again it has no RWDS, according to Theorem 2.6.
Case 3. If $n \geq 6$, the set $\{v_i, v_j\}; d(v_i, v_j) \geq 2$ is a minimum RWDSand the set $V - D$has no an isolated vertex. Thus, $\gamma_{rwh}(P_n) = 2$.
From all cases above, the result is obtained. □

Proposition 3.3. *The graphs* $\overline{W_n}, \overline{K_n}, \overline{S_n}$, *and* $\overline{K_{n,m}}$ *have no RWDS.*

Proof. All these graphs are disconnected. Thus, according to Theorem 2.5.
these graphs have no RWDS.□

4-Effective the deletion or addition

Theorem 4.1: LetG be a graph has RWDS D with $\gamma_{\mathrm{rwh}} -$ set and $\gamma_{\mathrm{rwh}}(\mathrm{G}) > 1$, then If $\mathrm{v} \in \mathrm{D}$ then $\gamma_{rwh}(G - v) < \gamma_{rwh}(G)$ otherwise all probability are possible.

Proof. Let D be a $\gamma_{rwh} -$ set of a graph G. Then there are two cases as follows:
Case 1: If a vertex v, where $v \in D$is deleting, then $\gamma_{rwh}(G - v) < \gamma_{rwh}(G)$.
Case 2: If we delete a vertex v, where $v \in V - D$, then three cases are obtained as follows:
1) If $v \in D'$ such that D' is RWDS$\gamma_{rwh} -$ set, then
$\gamma_{wh}(G - v\ ) < \gamma_{wh}(G)$.
2) If $|D| < |V - D|$ and $(V - D) - v$ has RWDS, then $\gamma_{rwh}(G - v\ ) = \gamma_{rwh}(G)$.
3) If $(V - D) - v$has an isolated vertex, then D is not RWDS. Thus, there are two subcases as follows.
Subcase 1. If there is other RWDS in $G - v$ say D', then $\gamma_{wh}(G - v\ ) > \gamma_{wh}(G)$.
Subcase 2. If there is no other RWDS in $G - v$, then $G - v$ has no RWDS.
From all cases above, the result is obtained.

Theorem 4.2. Let G be a graph has restrained whole domination number, then G has no RWDSor $\gamma_{\mathrm{rwh}}(\mathrm{G} - \mathrm{e}) \geq \gamma_{\mathrm{rwh}}(\mathrm{G})$.

Proof. There are several cases depending on the location of the edge $(e = uv)$as follows.
Case 1. If e belongs to the induced subgraph $\langle D \rangle$, then the deleting e not influence to the restrained whole domination.
Case 2. If e belongs to the induced subgraph $\langle V - D \rangle$, then there are two subcases as follows.
I) At least one vertex u or v becomes an isolated in $\langle V - D \rangle$ after deleting the edge e, then G has no restrained whole domination.
II) If u and v are not isolated vertices in$\langle V - D \rangle$after deleting the edge e, *then* the deleting e not influence to the restrained whole domination.
Case 3. If$u \in D$ *and* $v \in V - D$, then there are two subcases as follows.
I) If all vertices in the induced subgraph $\langle V - D \rangle$ are adjacent to a vertex v, then v will belongs to the set D after deleting the edge e. Therefore, $\gamma_{rwh}(G - e) > \gamma_{rwh}(G)$.
II)If all vertices in the induced subgraph $\langle V - D \rangle$ are not adjacent to a vertex v, then $G - e$ has no RWDS.
From all cases above, the result is obtained.□

Theorem 4.3.*If* G *has a* γ_{rwh} *,then*$\gamma_{rwh}(G + e) \leq \gamma_{rwh}(G)$, *where* $e \in \bar{G}$.

Proof.
Let D'' be a minimum RWDS that means$|D'| = \gamma_{rwh}$. By adding an edge e to a graph G, two different cases are gotten as follows.
Case1. If e joins two vertices from $V - D$, then the whole domination is not influenced by this addition. Thus, $\gamma_{rwh}(G + e) = \gamma_{rwh}(G)$.

Case2. If e joins two vertices in D, then if at least one vertex which is incident on this edge becomes adjacent to all vertices in D, then $\gamma_{rwh}(G+e)=1$.
Thus, $\gamma_{rwh}(G+e)\leq\gamma_{rwh}(G)$.
We cannot add an edge e to a graph G if one of its vertices belongs to the set D and the other belongs to the set $V-D$, since $e\notin\bar{G}$in this case according to definition of whole dominating set. Therefore, we get the result. □

Theorem 4.4. IfGhas a γ_{rwh} , then $\gamma_{\mathrm{rwh}}(\mathrm{G}\backslash\mathrm{e})\leq\gamma_{\mathrm{rwh}}(\mathrm{G})$.

Proof. Let D' be a γ_{rwh}- set of a graph G. By contracting an edge e of graph G, three different cases are obtained as follows.
Case 1. If we contract the edge e which is incident on two vertices of $V-D$, then there are two cases as follows.
(i) If $|D|=|V-D|$ then $V-D$ becomes the minimum RWDS. Thus, $\gamma_{rwh}(G\backslash e)<\gamma_{rwh}(G)$.
(ii) If $|D|<|V-D|$, then the minimum RWDS is not influenced by this contraction. Thus, $\gamma_{rwh}(G\backslash e)=\gamma_{rwh}(G)$.
Case 2. If contracting an edge e incident on two vertices from D, then it is clear that the set D is decreasing by one vertex and will still minimum RWDS. Thus,$\gamma_{rwh}(G\backslash e)<\gamma_{rwh}(G)$.
Case 3. If e is incident on two vertices one of them from $V-D$ and the other from D, then the new vertex obtained by this contraction is adjacent to all vertices in G, then $\gamma_{rwh}=1$
Therefore, from all cases above, $\gamma_{rwh}(G\backslash e)\leq\gamma_{rwh}(G)$. □

5. Conclusion

Throughout the results which are obtained in this work, new properties and boundaries of a new parameter are been getting. Also, for certain graphs as a cycle, complete, path, wheel, and complete bipartite are been determined of restrained whole domination. The complement of graphs especially the certain graphs are mentioned above are been determined of this number. Finally, the effective of deleting or adding an edge or deleting a vertex of the restrained domination number is discussed.

Abstract. The main objective of this paper is to classify the special sets in the projective planes PG (2, t) with the values of t=17,31,37, and we found the arcs of the second degree (k,2) - arcs in PG (2, t) or third-degree (k,3)-arcs in PG(2,t), and the parameters of codes n, k, d was calculated and whether they are complete or incomplete, and the corresponding codes were formed.

1. Introduction

This paper depends on the subject of finite projective geometry and the creation of full arcs in $PG(2,t)$ when $t = 17, 31, 37$. In general $PG(2,t)$ contains $t^2 + t + 1$ points, $t^2 + t + 1$ lines, $t + 1$ point on a line and $t + 1$ line passes through the point, We have used the GAP program [1]. All theorems of the research are taken from [2] such Sticker Classified special arcs in $PG(2,t)$, and the ideas of the research are taken from Hirshfeld [3]. The *Special* $(k, 2)$-arcs *in* $PG\ (2, t), t \leq 29$ have already been classified and we will work on values higher than 29, as well as *Special* $(k, 3)$-arcs in $PG(2,t)$, $t \leq 13$, that have already been classified and we will work on values higher than 13. For more information see[4], [5], [6], [7], [8], [9], [10], [11]. Some definitions are useful to our research are given as follows:

Definition 1.1 [3]: The arc is a $(k;n)$ arc in PG$(2,t)$ is a set of k points no n of them of collinear.

Definition 1.2 [3]: A linear code (n,k,d,t)-code C is a subspace of $V(n,t)= (F_t)^n$, where the dimension of C is dim $C = k$, n represents the number of arc elements, d represents the number of arc elements for except intersections and t is the number of field elements

Definition 1.3 [3]: c_i represents the number of points out on the arc K which are passes through them i bisecant of arc K.

Definition 1.4 [3]: A $(k;r)$-arc is called complete if it is not contained within $(k+1;r)$-arc.

2. Special $(\mathbf{k}, \mathbf{3})$- arcs in PG $(\mathbf{2}, \mathbf{q}), \mathbf{q} = \mathbf{17}$

When $q \leq 13$ rated this work. The following results are interesting to the area of research:

Theorem 2.1 [2]: Let $a \in F_q . q\ odd$. Let $S^*(a)$ denote the set of points of $PG(2,q)$ with coordinates of the from $[a,\pm1,\pm1]$, $[\pm1,a,\pm1]$ or $[\pm1,\pm1,a]$, with independent choices of the sign. Let $S^*(\infty)$ be the set of points with coordinates$[1,0,0],[0,1,0] or [0,0,1]$. The set $S^*(a) = S^*(-a)$ is a $(12,3)$ arc $of\ PG(2,q)$ if and only if

$$a \notin \{0,\pm1,\pm\sqrt{-1}\}. \quad (1)$$

The set $S^*(a) \cup S^*(\infty)$ is a $(15,3)$ arc $if\ and\ only\ if\ a\ satisfies$ (3.1).
The set $S^*(a) \cup S^*(0)$ is a $(18,3)$ arc $if\ and\ only\ if\ a\ satisfies$ (3.1) and

$$a \neq \pm2,\ a^2 \pm a \pm 2 \neq 0. \quad (2)$$

The values of
$a \in \{\pm2,\pm3,\pm4,\pm5,\pm6,\pm7,\pm8\}$.
Take $= 2$.
The points of the arc $S^*(2)$ are

$[2,1,1],[15,1,1],[15,16,1],[2,16,1],[1,2,1],[16,15,1],$
$[16,2,1],[1,15,1],[9,9,1],[8,8,1],[9,8,1],[8,9,1]$
The value of the parameter $c_0 = 0$, The arc $S^*(2)$ is complete because $c_0 = 0$.
Shaped code parameters are equivalent to this arc.(n, k, d, q)-code
$n = 12, k = 3, d = n - 3 = 9, q = 17$, The code elements are generated by the matrix,

$$G = \begin{pmatrix} 2 & 15 & 15 & 2 & 1 & 16 & 16 & 1 & 9 & 8 & 9 & 8 \\ 1 & 1 & 16 & 16 & 2 & 15 & 2 & 15 & 9 & 8 & 8 & 9 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{pmatrix}$$

The element of the code represents
$X = \lambda_1 R_1 + \lambda_2 R_2 + \lambda_3 R_3$
The elements $\lambda_1, \lambda_2, \lambda_3$, in F_{17} and R_1, R_2, R_3 are rows of generated matrix G
The size the code is $q^k = 17^3 = 49135$, some points of code are
$X_1 = [0,0,0,0,0,0,0,0,0,0,0,0]$
$X_2 = [1,1,1,1,1,1,1,1,1,1,1,1]$
$X_3 = [1,1,16,16,2,15,2,15,9,8,8,9]$
$X_4 = [2,15,15,2,1,16,16,1,9,8,9,8]$
$X_5 = [3,16,14,1,3,14,1,16,1,16,0,0]$
$X_6 = [3,16,16,3,2,0,0,2,10,9,10,9]$
$X_7 = [2,2,0,0,3,16,3,16,10,9,9,10]$
$X_8 = [4,0,15,2,4,15,2,0,2,0,1,1]$

The points of the arc $S^*(a) \cup S^*(\infty)$ are Where $a = 2$,
$[2,1,1],[15,1,1],[15,16,1],[2,16,1],[1,2,1],[16,15,1],[16,2,1],$
$[1,15,1],[9,9,1],[8,8,1],[9,8,1],[8,9,1],[1,0,0],[0,1,0],[0,0,1]$

The value of the parameter $c_0 = 4$, The arc $S^*(2) \cup S^*(\infty)$ is not complete because $c_0 \neq 0$.
Shaped code parameters equivalent to this arc, (n, k, d, q)- code
$n = 15$, $k = 3$, $d = n - 3 = 12$, $q = 17$,
The code elements are generated by the matrix,

$$G=\begin{pmatrix}2&15&15&2&1&16&16&1&9&8&9&8&1&0&0\\1&1&16&16&2&15&2&15&9&8&8&9&0&1&0\\1&1&1&1&1&1&1&1&1&1&1&1&0&0&1\end{pmatrix}$$

some points of code are
$X_1 = [0,0,0,0,0,0,0,0,0,0,0,0,0,0,0]$
$X_2 = [1,1,1,1,1,1,1,1,1,1,1,1,0,0,1]$
$X_3 = [1,1,16,16,2,15,2,15,9,8,8,9,0,1,0]$
$X_4 = [2,15,15,2,1,16,16,1,9,8,9,8,1,0,0]$
$X_5 = [3,16,14,1,3,14,1,16,1,16,0,0,1,1,0]$
$X_6 = [3,16,16,3,2,0,0,2,10,9,10,9,0,1,1]$
$X_7 = [2,2,0,0,3,16,3,16,10,9,9,10,1,2,1]$
$X_8 = [4,0,15,2,4,15,2,0,2,0,1,1,1,1,1]$

By the same way for $S^*(b) \cup S^*(\infty)$ with $b \in \{\pm3, \pm4, \pm5, \pm6, \pm7, \pm8\}$.
The values of $a \in \{\pm3, \pm4, \pm5, \pm6, \pm7, \pm8\}$
Which satisfies condition $a \neq \pm2$, $a^2 \pm a \pm 2 \neq 0$.
Take $a = 3$, the points of the arc $S^*(3) \cup S^*(0)$ are
$[3,1,1], [14,1,1], [14,16,1], [3,16,1], [1,3,1], [16,14,1], [16,3,1], [1,14,1], [6,6,1], [11,11,1],$
$[6,11,1], [11,6,1], [1,1,0], [16,1,0], [1,0,1], [16,0,1], [0,1,1], [0,16,1]$
The value of the parameter $c_0 = 7$, The arc $S^*(3)$ is not complete because $c_0 \neq 0$.
Shaped code parameters equivalent to this arc, (n, k, d, q)- code $n = 18$, $k = 3$, $d = n - 3 = 15$, $q = 17$,
The code elements are generated by the matrix,

$$G=\begin{pmatrix}3&14&14&3&1&16&16&1&6&11&6&11&1&16&1&16&1&0\\1&1&16&16&3&14&3&14&6&11&11&6&1&1&0&0&0&16\\1&1&1&1&1&1&1&1&1&1&1&1&0&0&1&1&1&1\end{pmatrix}$$

Some points of code are
$X_1 = [0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0]$
$X_2 = [1,1,1,1,1,1,1,1,1,1,1,1,0,0,1,1,1,1]$
$X_3 = [1,1,16,16,3,14,3,14,6,11,11,6,1,1,0,0,0,16]$
$X_4 = [3,14,14,3,1,16,16,1,6,11,6,11,1,16,1,16,0,0]$
$X_5 = [4,15,13,2,4,13,2,15,12,5,0,0,2,0,1,16,0,16]$
$X_6 = [4,15,15,4,2,0,0,2,7,12,7,12,1,0,2,0,1,1]$
$X_7 = [2,2,0,0,4,15,7,15,7,12,12,0,1,1,1,1,1,0]$
$X_8 = [5,16,14,3,5,16,3,16,13,6,1,1,2,0,2,0,2,0]$
By the same way for $S^*(k) \cup S^*(0)$ with $k \in \{\pm4, \pm5, \pm6, \pm7, \pm8\}$.
Another result is also important to our research:

Theorem 2.2 [2]: Let $q \equiv 1 \bmod 4$. Let $a, i \in F_q$,such that $i^2 = -1$. Let $S^*(a)$ be defined as in Theorem 2.1. Let I denote the set of six points whose coordinates are permutations of $[1, i, 0]$. (I is a subset of the conic $C: x^2 + y^2 + z^2 = 0$).
Then $S^*(a) \cup I$ is an $(18,2)$ arc $of\ PG(2,q)$ if and only if $a \notin \{0, \pm1, \pm i, \pm i \pm 1, \pm 2i,\}$.
The values of $a \in \{\pm2, \pm6, \pm7\}$.
And values $i = 4, 13$
The points of the arc I_1 are [13,1,0], [13,0,1], [4,1,0], [4,0,1], [0,4,1], [0,13,1].
The points of the arc I_2 are [4,1,0], [4,0,1], [13,1,0], [13,0,1], [0,13,1], [0,4,1].
is a subset of the conic $C: x^2 + y^2 + z^2 = 0$
The arcs $S^*(j) \cup I_1$, $S^*(j) \cup I_2$ are $(18,2)$ arc $of\ PG(2,q)$, $k \in \{\pm2, \pm6, \pm7\}$.

Where $a = 2$, the points of the arc $S^*(2)$ are:

$[2,1,1],[15,1,1],[15,16,1],[2,16,1],[1,2,1],[16,15,1],[16,2,1],[1,15,1],[9,9,1],[8,8,1],$
$[9,8,1],[8,9,1].$

Take $S^*(2) \cup I_1$, the value of the parameter $c_0 = 0$, The arc $S^*(2) \cup I_1$ is complete because $c_0 = 0$,
Parameters of the formed code equivalent to this arc , (n, k, d, q)- code $n = 18$, $k = 3$, $d = n - 3 = 15$, $q = 17$.
The code elements are generated by the matrix,

$$G = \begin{pmatrix} 2 & 15 & 15 & 2 & 1 & 16 & 16 & 1 & 9 & 8 & 9 & 8 & 13 & 13 & 4 & 4 & 0 & 0 \\ 1 & 1 & 16 & 16 & 2 & 15 & 2 & 15 & 9 & 8 & 8 & 9 & 1 & 0 & 1 & 0 & 4 & 13 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 \end{pmatrix}$$

some o points of code are
$X_1 = [0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0]$
$X_2 = [1,1,1,1,1,1,1,1,1,1,1,1,0,1,0,1,1,1]$
$X_3 = [1,1,16,16,2,15,2,15,9,8,8,9,1,0,1,0,4,13]$
$X_4 = [2,15,15,2,1,16,16,1,9,8,9,8,13,13,4,4,0,0]$
$X_5 = [3,16,14,1,3,14,1,16,1,16,0,0,14,13,5,4,4,13]$
$X_6 = [3,16,16,3,2,0,0,2,10,9,10,9,13,14,4,5,1,1]$
$X_7 = [2,2,0,0,3,16,3,16,10,9,9,10,1,1,1,1,5,14]$
$X_8 = [4,0,15,2,4,15,2,0,2,0,1,1,14,14,5,5,5,14]$
In the same way for $S^*(b) \cup I_1$ with $\in \{\pm 6, \pm 7\}$. And $S^*(k) \cup I_2$, $k \in \{\pm 2, \pm 6, \pm 7\}$

3. Special (k,2)- arcs in PG (2,q),q=31

The following results are interesting to the area of research:

Theorem 3.1 [2]: Let $a \in F_q$, q odd. Let $S^*(a)$ denote the set of points of $PG(2,q)$ with Coordinates of the from $[a, \pm 1, \pm 1]$, $[\pm 1, a, \pm 1]$ *or* $[\pm 1, \pm 1, a]$, with independent choices of the sign is a $(12,2)$ arc of $PG(2,q)$ if and only if then $S^*(a) = S^*(-a)$,
$a \notin \{0, \pm 1, \pm 2, \pm\sqrt{-1}, \pm\sqrt{-3}, \frac{1}{2}(\pm 1 \pm \sqrt{-7})\}$.
If these conditions hold, then, if $a^2 = -2$, the point of $S^*(a)$ lie on the conic C with equation
$C: x^2 + y^2 + z^2 = 0$,
Otherwise $S^*(a)$ is the disjoint union of three sets $C_0 \cap C_1, C_1 \cap C_2, C_2 \cap C_0$ of size 4 which are the pairwise intersections of the three conics C_0, C_1, C_2 with equations
$C_0: (a^2+1)x^2 = y^2 + z^2$,
$C_1: (a^2+1)y^2 = z^2 + x^2$,
$C_2: (a^2+1)z^2 = x^2 + y^2$,
The values of $a \in \{\pm 3, \pm 4, \pm 5, \pm 6, \pm 7, \pm 8, \pm 9, \pm 10, \pm 12, \pm 13, \pm 14, \pm 15\}$,
Take $a = 3$, the points of the arc $S^*(3)$ are:
$[3,1,1],[1,3,1],[21,21,1],[28,30,1],[30,3,1],[21,10,1],[3,30,1],[30,28,1],[10,21,1],[28,1,1],[1,28,1],[10,10,1]$
The values of the parameters c_i , $i = 0, \ldots, 6$, are respectively, $[c_0, \ldots, c_6] =$
$[90, 314, 371, 172, 32, 2, 0]$
The arc $S^*(3)$ is not complete because $c_0 \neq 0$.
shaped code parameters equivalent to this arc , (n, k, d, q)- code,
$n = 12$, $k = 3$, $d = n - 2 = 10$, $q = 31$,
The code elements are generated by the matrix,

$$G = \begin{pmatrix} 3 & 28 & 3 & 21 & 1 & 30 & 30 & 1 & 21 & 21 & 10 & 10 \\ 1 & 30 & 30 & 1 & 3 & 28 & 3 & 28 & 21 & 10 & 21 & 10 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{pmatrix}$$

The element of the code represents $X = \lambda_1 R_1 + \lambda_2 R_2 + \lambda_3 R_3$
The elements $\lambda_1, \lambda_2, \lambda_3$, in F_{31} and R_1, R_2, R_3 are rows of generated matrix G
The size the code is $q^k = 31^3 = 297915$, some points of code are
$X_1 = [0,0,0,0,0,0,0,0,0,0,0,0]$
$X_2 = [1,1,1,1,1,1,1,1,1,1,1,1]$
$X_3 = [1,30,30,1,3,28,3,28,21,10,21,10]$
$X_4 = [3,28,3,21,1,30,30,1,21,21,10,10]$
$X_5 = [4,27,2,22,4,27,2,29,11,0,0,20]$
$X_6 = [4,29,4,22,2,0,0,2,22,22,11,11]$
$X_7 = [2,0,0,2,4,29,4,29,22,11,22,11]$
$X_8 = [5,28,3,23,5,28,3,30,12,1,1,21]$
Since $a^2 \neq -2$ so the points
$[21,21,1], [21,10,1], [10,21,1], [10,10,1]$ are belong to $C_0 \cap C_1$
$[1,3,1], [30,3,1], [30,28,1], [1,28,1]$ are belong to $C_2 \cap C_0$
$[3,1,1], [28,30,1], [3,30,1], [28,1,1]$ are belong to $C_1 \cap C_2$
In the same way for $S^*(b)$ with
$b \in \{\pm 4, \pm 5, \pm 6, \pm 7, \pm 8, \pm 9, \pm 10, \pm 12, \pm 13, \pm 14, \pm 15\}$,
Another result is also important to our research:

Theorem 3.2 [2]: Let $q = 0,1 \ or \ 4 \bmod 5$, q odd. Let $\tau = \frac{\sqrt{5}+1}{2}$. consider the following sets:
$R = \{[0,1,\pm\tau], [1,\pm\tau,0], [\pm\tau,0,1]\}$,
$S = [0,\pm\tau,\pm\tau^{-1}], [\pm\tau,\pm\tau^{-1},0], [\pm\tau^{-1},0,\pm\tau], [\pm 1,\pm 1,\pm 1]$.
The set R is a $(6,2)$ arc $of\ PG(2,q)$. The set S is a $(10,2)$ arc $of\ PG(2,q)$ if and only if $q \neq 0 \bmod 5$.
The values of $\tau = 13, 19$.
The points of the arc R when $\tau = 13$ are $[0,12,1], [0,19,1], [12,1,0], [19,1,0], [13,0,1], [18,0,1]$
The points of the arc R when $\tau = 19$ are $[0,18,1], [0,13,1], [1,19,0], [1,12,0], [19,0,1], [12,0,1]$
$\tau = 1$ Take the values of the parameters c_i, $i = 0, \ldots, 3$, are respectively,
$[c_0, c_1, c_2, c_3] = [572, 390, 15, 10]$
The arc R is not complete because $c_0 \neq 0$, shaped code parameters equivalent to this arc (n, k, d, q)- code,
$n = 6,\ k = 3,\ d = n - 2 = 4,\ q = 31,$
The code elements are generated by the matrix,

$$G = \begin{pmatrix} 0 & 0 & 12 & 19 & 13 & 18 \\ 12 & 19 & 1 & 1 & 1 & 0 \\ 1 & 1 & 0 & 0 & 1 & 1 \end{pmatrix}$$

some points of code are
$X_1 = [0,0,0,0,0,0]$
$X_2 = [1,1,0,0,1,1]$
$X_3 = [12,19,1,1,1,0]$
$X_4 = [0,0,12,19,13,18]$
$X_5 = [12,19,13,20,14,18]$
$X_6 = [1,1,12,19,14,19]$
$X_7 = [13,20,1,1,2,1]$
$X_8 = [13,20,13,20,15,19]$
By the same way for $\tau = 19$.

The points of the arc S when $\tau = 13$ are
$[1,1,1], [30,1,1], [1,30,1], [30,30,1], [0,14,1], [13,12,0], [20,0,1], [0,17,1], [17,1,0], [11,0,1]$
The points of the arc S when
$\tau 19$ are$[1,1,1], [30,1,1], [1,30,1], [30,30,1], [0,20,1], [19,18,0], [14,0,1], [0,11,1], [11,1,0], [17,0,1],$
Take $\tau = 13$
The values of the parameters c_i , $i = 0, \dots, 5$, are respectively,
$[c_0 , \dots, c_5] = [134 , 460 , 294 , 78 , 17, 0]$
The arc S is not complete because $c_0 \neq 0$.
shaped code parameters equivalent to this arc, (n , k , d , q)- code
$n = 10$, $k = 3$, $d = n - 2 = 8$, $q = 31$,
The code elements are generated by the matrix,

$$G = \begin{pmatrix} 1 & 30 & 1 & 30 & 0 & 13 & 20 & 0 & 17 & 11 \\ 1 & 1 & 30 & 30 & 14 & 12 & 0 & 17 & 1 & 0 \\ 1 & 1 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \end{pmatrix}$$

some of point of code are
$X_1 = [0 , 0 , 0 , 0 , 0 , 0 , 0 , 0 , 0 , 0]$
$X_2 = [1 , 1 , 1 , 1 , 1 , 0 , 1 , 1 , 0 , 1]$
$X_3 = [1, 1, 30 , 30 , 14, 12, 0, 17, 1, 0]$
$X_4 = [1, 30, 1, 30, 0, 13, 20, 0, 17, 11]$
$X_5 = [1, 0, 0, 29, 14, 25, 20, 17, 18, 11]$
$X_6 = [2 , 0 , 2 , 0 , 1, 13, 21, 1, 17, 12]$
$X_7 = [2 , 2 , 0 , 0 , 15 , 12, 1, 18, 1, 1]$
$X_8 = [3, 1, 1, 30, 15, 25, 21, 18, 18, 12]$
In the same way for $\tau = 19$.

4. Special (k,2)- arcs in PG (2,q),q=37

The following results are interesting to the area of research:

Theorem 4.1 [2]: Let $q \equiv 1 \bmod 4$. Let $a, i \in F_q$, such that $i^2 = -1$. Let $S^*(a)$ be defined as in Theorem 3.1. Let I denote the set of six points whose coordinates are permutations of $[1, i, 0]$. (I is a subset of the conic $C : x^2 + y^2 + z^2 = 0$)
Then $S^*(a) \cup I$ is an $(18,2)$ arc $of\ PG(2, q)$ if and only if
$$a \notin \left\{0, \pm 1, \pm 2, \pm i, \pm 2i, \pm i\sqrt{3}, \pm i + 1, \frac{1}{2}\left(\pm 1 \pm i\sqrt{7}\right), \frac{1}{2}\left(\pm i \pm \sqrt{-5 \pm 4i}\right)\right\}$$
The values of $a \in \{\pm 3 , \pm 4 , \pm 10 , \pm 11 , \pm 13 , \pm 14 , \pm 15 , \pm 17 , \pm 18 \}$
And values $i = 6, 31$
The points of the arc I_1 are $[31,1,0], [31,0,1], [6,1,0], [6,0,1], [0,6,1], [0,31,1]$
The points of the arc I_2 are $[6,1,0], [6,0,1], [31,1,0], [31,0,1], [0,31,1], [0,6,1]$
is a subset of the conic $C : x^2 + y^2 + z^2 = 0$
The arcs $S^*(k) \cup I_1$, $S^*(k) \cup I_2$ are $(18,2)$ arc $of\ PG(2, q)$
$k \in \{\pm 3, \pm 4 , \pm 10 , \pm 11 , \pm 13 , \pm 14 , \pm 15, \pm 17 , \pm 18\}$,
Where $a = 3$, the points of the arc $S^*(3)$ are
$[3, 1, 1], [1 , 3, 1], [25,25,1], [34,36,1], [36, 34,1], [25,12,1], [3,36,1] , [36,3,1], [12,25,1], [34,1,1], [1,34,1] , [12,12,1]$
Take $S^*(3) \cup I_1$,
The values of the parameters c_i , $i = 0, \dots, 9$, are respectively,
$[c_0 , \dots, c_9] = [193, 480, 438, 195, 71, 9, 3, 0, 0, 0]$
The arc $S^*(3) \cup I_1$ is not complete because $c_0 \neq 0$.
shaped code parameters equivalent to this arc, (n , k , d , q)- code

$n = 18$, $k = 3$, $d = n - 2 = 16$, $q = 37$,
The code elements are generated by the matrix,

$$G = \begin{pmatrix} 3 & 1 & 25 & 34 & 36 & 25 & 3 & 36 & 12 & 34 & 1 & 12 & 31 & 31 & 6 & 6 & 0 & 0 \\ 1 & 3 & 25 & 36 & 34 & 12 & 36 & 3 & 25 & 1 & 34 & 12 & 1 & 0 & 1 & 0 & 6 & 31 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 \end{pmatrix}$$

The elements λ_1 , λ_2 , λ_3, in F_{37} and R_1, R_2, R_3 are rows of generated matrix G
The size the code is $q^k = 37^3 = 506535$, some points of code are
$X_1 = [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]$
$X_2 = [1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]$
$X_3 = [1, 3, 25, 36, 34, 12, 36, 3, 25, 1, 34, 12, 1, 0, 1, 0, 6, 31]$
$X_4 = [3, 1, 25, 34, 36, 25, 3, 36, 12, 34, 1, 12, 31, 31, 6, 6, 0, 0]$
$X_5 = [4, 4, 13, 33, 33, 0, 2, 2, 0, 35, 35, 24, 32, 31, 7, 6, 6, 31]$
$X_6 = [4, 4, 26, 35, 0, 26, 4, 0, 13, 35, 2, 13, 31, 32, 6, 7, 1, 1]$
$X_7 = [2, 4, 26, 0, 35, 13, 0, 4, 26, 2, 35, 13, 1, 1, 1, 1, 7, 32]$
$X_8 = [5, 5, 14, 34, 34, 1, 3, 3, 1, 36, 36, 25, 33, 32, 8, 7, 7, 32]$
In the same way for $S^*(j) \cup I_1$ with $j \in \{\pm 4, \pm 10, \pm 11, \pm 13, \pm 14, \pm 15, \pm 17, \pm 18\}$,
And $S^*(w) \cup I_2$, $w \in \{\pm 3, \pm 4, \pm 10, \pm 11, \pm 13, \pm 14, \pm 15, \pm 17, \pm 18\}$,
Another result is also important to our research:

Theorem 4.2 [2]: Let $q \equiv 1 \bmod 4$. Let $i \in F_q$ such that $i^2 = -1$. Let $S^*(1)$ denote the set of points of $PG(2, q)$ with coordinates $[1,1,1], [-1,1,1], [1,-1,1]$ *or* $[1,1,-1]$. Let I be defined as in Theorem 4.1. Then $S^*(1) \cup I$ *is* a $(10,2)$ arc *of* $PG(2, q)$ if and only if $i^2 \neq \pm 2$.
The point of the arc $S^*(1)$ are $[1,1,1], [36,1,1], [1,36,1], [36,36,1]$,
The arcs $S^*(k) \cup I_1$, $S^*(k) \cup I_2$ are $(10,2)$ arc *of* $PG(2, q)$
The points of the arc I_1 are $[31,1,0], [31,0,1], [6,1,0], [6,0,1], [0,6,1], [0,31,1]$
The points of the arc I_2 are $[6,1,0], [6,0,1], [31,1,0], [31,0,1], [0,31,1], [0,6,1]$
Take $S^*(1) \cup I_1$. The values of the parameters c_i , $i = 0, \dots, 5$, are respectively,
$[c_0, \dots, c_5] = [772, 515, 92, 17, 1, 0]$
The arc $S^*(1) \cup I_1$ is not complete because $c_0 \neq 0$.
shaped code parameters equivalent to this arc, (n, k, d, q)- code
$n = 10$, $k = 3$, $d = n - 2 = 8$, $q = 37$,
The code elements are generated by the matrix,

$$G = \begin{pmatrix} 1 & 36 & 1 & 36 & 31 & 31 & 6 & 6 & 0 & 0 \\ 1 & 1 & 36 & 36 & 1 & 0 & 1 & 0 & 6 & 31 \\ 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 \end{pmatrix}$$

some points of code are
$X_1 = [0, 0, 0, 0, 0, 0, 0, 0, 0, 0]$
$X_2 = [1, 1, 1, 1, 0, 1, 0, 1, 1, 1]$
$X_3 = [1, 1, 36, 36, 1, 0, 1, 0, 6, 31]$
$X_4 = [1, 36, 1, 36, 31, 31, 6, 6, 0, 0]$

E-mail: saad_alazawi@uomosul.edu.iq

Abstract. This paper derived a new simple hyperchaotic system from the famous Sprott, S system via the linear state feedback control. Compared with the available systems, the new system has eight terms, one constant, two parameters control, and a single quadratic nonlinear term. So this system is considered a simple relying on the number of terms and nonlinearities. The proposed system without equilibrium points and exhibits chaotic hidden attractors. Also, multistability or coexisting attractors are found through experimental simulations using phase portraits and the Lyapunov spectrum. Finally, anti-synchronization is implemented in the new system.

1. Introduction

In 2011, Leonov et al. introduced a new concept in the behavior of dynamic systems based on the attractors of these systems and it is classified into two categories: hidden and self-excited attractors [1]. Most of the famous traditional systems such as Lorenz 1963, Rossler 1976, Chen 1999, and Liu systems 2004 have self-excited attractors [2-6]. Whereas the hidden attractor occur sin three cases; systems with stable equilibrium points [7-9], no-equilibrium points [10-16], many or line equilibria [17]. Hidden attractors are difficult to discover compared with self-excited attractors, since the location of the equilibrium points not necessary as it is in self-excited attractors.

In literature, many works have been concentrated on the discovery of simple chaotic and hyperchaotic systems with no equilibrium points. In 1994, the researcher Sprott presented 19 systems of three-dimensional that were classified into two groups based on the number of terms and nonlinearities, the first group of systems consisting of five terms with two nonlinear (A-E) whereas the second group consisting of six terms with one nonlinear (F-S) [18]. The number of terms and number of quadratic or cubic nonlinearities are important factors within the simplest systems. In 2011, Wei reported 3D chaotic system without equilibrium points containing five terms which include two [11]. In 2012, Wang et al. [15] presented a no-equilibrium 4D hyperchaotic system from on the Sprott A system, this system has a total of nine terms including five nonlinearities. In 2013, Jafari et al. [19] proposed 17 systems without equilibrium points with quadratic nonlinearities. In 2014, Wei et al. introduced a no-equilibrium 4D hyperchaotic system which has a total of eight terms, including two nonlinearities [20]. In 2019, Zhang and Zeng reported a no-equilibrium simple 3D system has a quadratic term and a square nonlinrartlty [21]. More recently, Zhang et al. in 2020, present a new simple 3D system without equilibrium points have six terms without any nonlinear term [22].

Recently, many synchronization phenomena have implementation of these systems due to their important applications in such as engineering [23, 24], and encryption [25-28]. Various schemes of synchronization were reported such as complete synchronization (CS) [2, 3, 29, 30], anti-synchronization (AS) [31-33], hybrid synchronization (HS) [34-36], projective synchronization (PS) [32-34].
The following points summarize the main contribution of this work, the proposed system as below:

(i) A 4D simple hyperchaotic Sprott S is constructed from the famous 3D Sprott-S system.
(ii) Without equilibrium point.
(iii) Consists of eight terms containing one constant two parameters control and one nonlinear term. So it can be considered one of the simplest systems.
(iv) Exhibit coexisting of attractors.
(v) Implementing the phenomenon of anti-synchronization of this system.

2. Dynamics of the 4D hyperchaotic Sprott S system

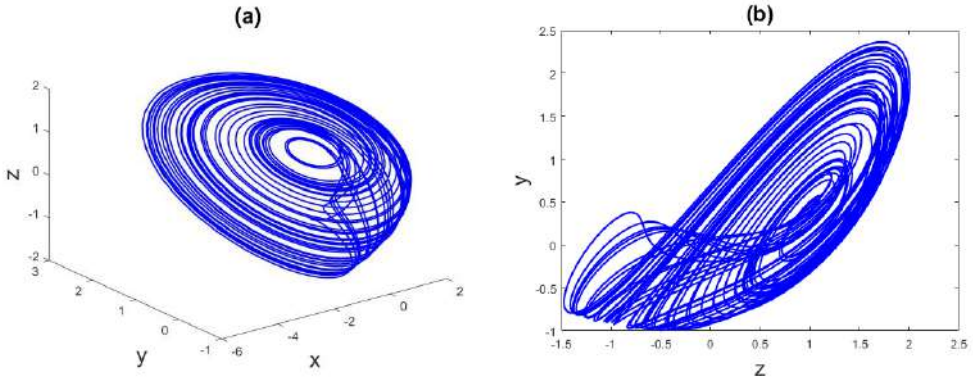
The Sprott S system [18] is depicted as:

$$\begin{cases} \dot{x} = -x - 4y, \\ \dot{y} = x + z^2, \\ \dot{z} = 1 + x\,, \end{cases} \tag{1}$$

in which $[x, y, z]^T \in R^3$ is a state vector. Based on the state feedback control [37, 38] by adding a linear controller to the second equation of (1), a new simple 4D chaotic quadratic system is obtained as:

$$\begin{cases} \dot{x} = -x - 4y, \\ \dot{y} = x + z^2 + aw, \\ \dot{z} = 1 + x\,, \\ \dot{w} = -by, \end{cases} \tag{2}$$

in which $[x, y, z, w]^T \in R^4$ is state vector. The parameters a and b are two positive constants. This system has eight terms with six linear terms, single quadratic nonlinearity, and one constant. With $a = 0.01$, $b = 0.1$ and $x(0) = (0.1, 0.1, 0.1, 0.1)^T$, this is system exhibit chaotic hidden attractors as shown in Figure 1.



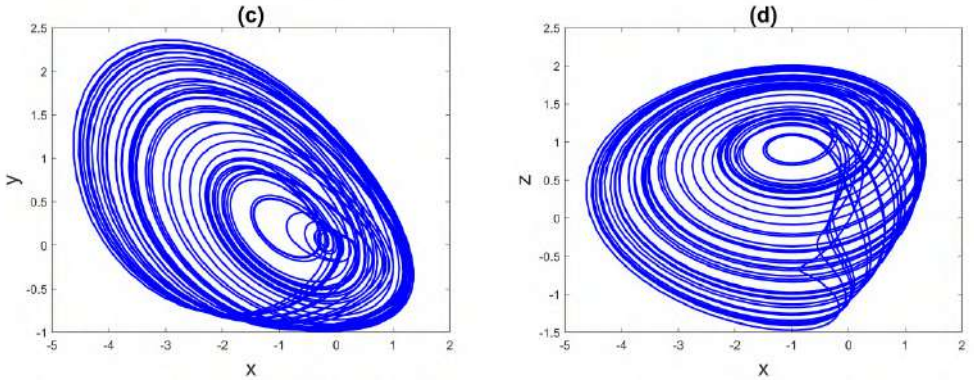


Figure 1. The chaotic hidden attractors of system (2) in: (**a)** $x-y-z$ space, (**b**): $y-z$ plane, (**c**): $x-y$ plane, and (**d**): $x-z$ plane.

2.1 Equilibrium points and Stability

The equilibrium points are established by Solving the following equations

$$\begin{cases} -x-4y=0 \\ x+z^2+au=0 \\ 1+x=0 \\ -by=0 \end{cases} \tag{3}$$

From the third and fourth equations of (3), it is seen that $x=1, y=0$, respectively. This leads to a contradiction with the first equation of (3). Consequently, the system (2) without equilibrium points concludes that this system with hidden attractors.

2.2 Lyapunov exponents and dissipativity

Wolf Algorithm has received increasing attention over the past decades due to the applications of calculating Lyapunov exponents (LE_S). With parameters $a=0.02$, $b=0.001$ and the initial condition $(0.5,0.5,0.5,0.5)^T$, step $\Delta t=0.25$, observation time $T=300$, the LE_S of the 4D system (2) are numerically obtained in MATLAB simulation as

$$\begin{cases} LE_1=0.1658 \\ LE_2=0 \\ LE_3=-0.0299 \\ LE_4=-1.1353 \end{cases} \tag{4}$$

Figure 2. depict the corresponding Lyapunov spectrum of (4) and the Lyapunov dimension (Kaplan-Yorke dimension) [17] of this system is calculated as

$$D_{LE}=j+\frac{1}{|LE_{j+1}|}\sum_{i=1}^{j}LE_i=3+\frac{LE_1+LE_2+LE_3}{|LE_4|}=3.1197$$

Since that the sum of the Lyapunov exponents ($\sum \mathrm{LE}_S=-1$) is negative, which indicate its dissipative system and meanwhile the divergence of the proposed system is equal (-1) i.e.

$$\nabla v=\frac{\partial \dot{x}}{\partial x}+\frac{\partial \dot{y}}{\partial y}+\frac{\partial \dot{z}}{\partial z}+\frac{\partial \dot{u}}{\partial u}=-1$$

Which is equal or almost to the sum of the Lyapunov exponents. So, that they fulfill the Lyapunov exponents (4) such as $\sum \mathrm{LE}_S=\nabla v$.

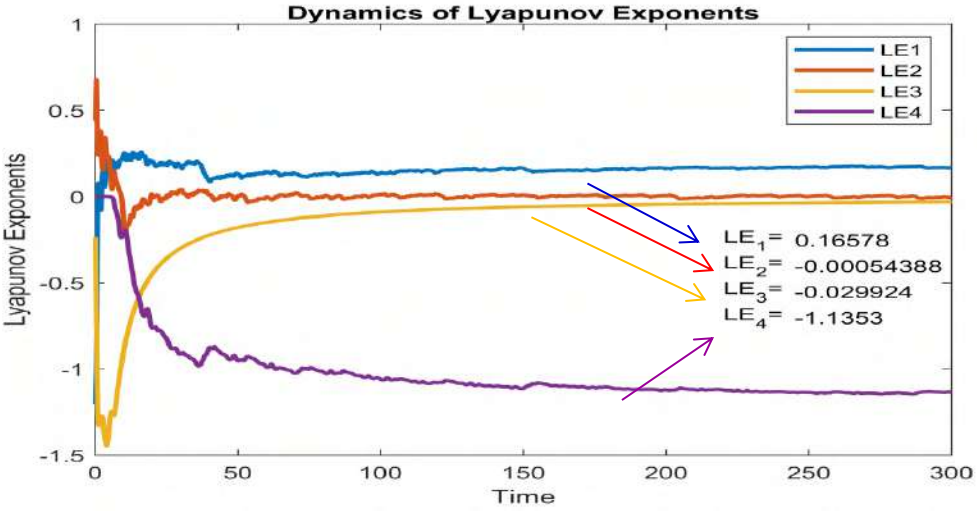

Figure 2. Lyapunov spectrum of the system (2) for $a = 0.02, b = 0.001$.

With various values of the system's parameters and various initial, Tables 1-2 depicts more details about calculating LE_S.

Table 1. LE_S of system (2) for $a = 0.02$ with varying the b and $(0.5, 0.5, 0.5, 0.5)^T$.

No.	b	LE_S	Sum of LE_S	Sign of the LE_S
1.	0.001	$0.1658, -0.0005, -0.03, -1.1353$	-1	$(+,0,-,-)$
2.	0.004	$0.1886, 0.0004, -0.0253, -1.1637$	-1	$(+,0,-,-)$
3.	0.005	$0.1621, 0.0004, -0.0246, -1.1379$	-1	$(+,0,-,-)$
4.	0.0002	$0.1942, 0.0009, -0.0353, -1.1599$	-1.0001	$(+,0,-,-)$
5.	0.0006	$0.1903, 0.0005, -0.0316, -1.1592$	-1	$(+,0,-,-)$
6.	0.0008	$0.1469, 0.0005, -0.0307, -1.1168$	-1.0001	$(+,0,-,-)$

Table 2. LE_S of system (2) for $b = 0.04$ with varying the a and $(0.7, 0.7, 0.7, 0.7)^T$.

No.	a	LE_S	Sum of LE_S	Sign of the LE_S
1.	0.006	$0.1964, 0.0009, -0.0165, -1.1808$	-1	$(+,0,-,-)$
2.	0.0004	$0.2103, 0.0003, -0.0165, -1.194$	-0.9999	$(+,0,-,-)$
3.	0.0006	$0.1849, -0.0001, -0.0165, -1.1682$	-0.9999	$(+,0,-,-)$
4.	0.0008	$0.1954, -0.0007, -0.0165, -1.1782$	-1	$(+,0,-,-)$

It is seen from Tables 1-2, although the proposed system has four dimensions, this extended dimension is one of the important requirements for generating hyperchaotic attractors. But we don't get $(+,+,0,-)$ sign of LE_S which indicates its the system (2) with chaotic hidden attractors. Also, the sum of the LE_S is almost equal to (-1) ,and that matches with divergence.

3. Multistability behavior of the proposed system

Coexisting attractors or Multistability means that the dissipative system has different trajectories under the same set of parameters and different combinations of and initial values [14]. The proposed system has multistability behavior or coexistence of chaotic hidden attractors. All of Figures 3. and 4., exhibit multistability phenomena which include four different hidden attractors with various initial values. With the parameters are set as $a = 8$, $b = 80$ and initial values $[-2.7, 2.7, 2.7, 2.7]^T$(red) and $[2.7, 2.7, 2.7, 2.7]$ (blue) as shown in Figure 3.a whereas in Figure 3.b with initial values $[-10.8, 2.7, 2.7, 2.7]^T$(red) and $[-0.1, 2.7, 2.7, 2.7]$ (blue). Under the parameters $a = 5$, $b = 20$, with

initial values with initial values $[-0.5,-0.5,-0.5,-5]^T$(red) and $[-0.5,-0.5,-0.5,-2]$ (blue) as shown in Figure 4.a whereas the initial values are $[-0.5,-0.5,-0.5,-5]^T$(red) and $[-0.5,-0.5,-0.5,-2]$ as shown in Figure 4.b.

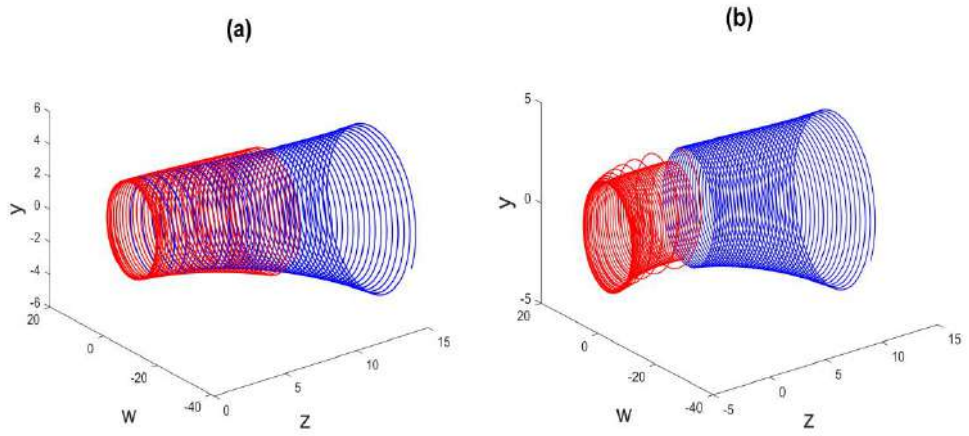

Figure 3. Coexistences of two different attractors for system (2) with $a = 8$, $b = 80$ and initial conditions $y(0) = z(0) = w(0) = 2.7$. (a) coexistences attractors with $x(0) = -2.7$ (red) and $(0) = 2.7$ (blue), (b) coexistences attractors with $x(0) = -10..8$ (red) and $(0) = -0.1$.

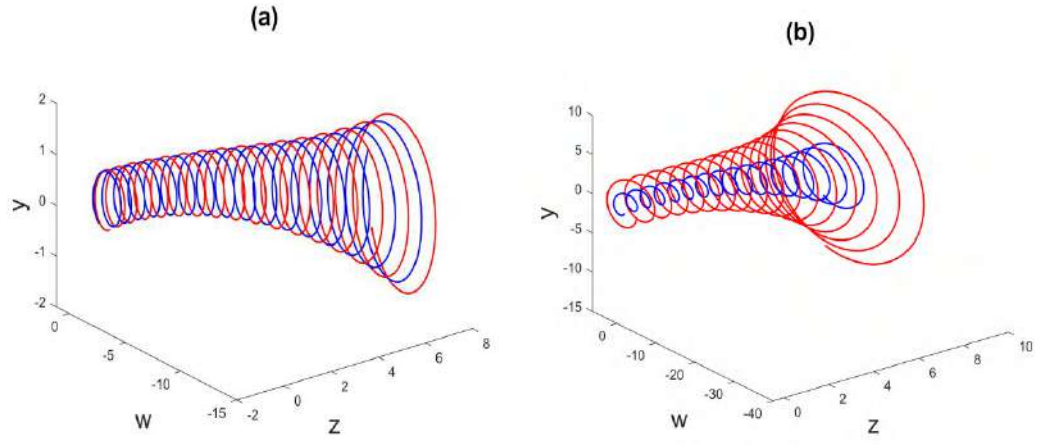

Figure 4. Coexistences of two different attractors for system (2) with $a = 5$, $b = 20$ and initial conditions conditions $x(0) = y(0) = z(0) = -0.5$. (a) coexistences attractors with $w(0) = -0.5$ (red) and $w(0) = 0.5$ (blue), (b) coexistences attractors with $w(0) = -5$ (red) and $w(0) = -2$ (blue).

4. Anti-synchronization between identical new systems

In this section, anti-synchronization is realized between two identical system (2) drive and response systems which described as

$$\dot{x} = Ax + f(x) \quad (5)$$

$$\dot{y} = By + g(y) + U \quad (6)$$

In which $x, y \in R^4$ are the state variables, $A, B \epsilon R^{4\times4}$ are matrices of system's parameters, $f, g: R^n \rightarrow R^n$ are nonlinear functions, $U \in R^4$ is nonlinear controller. The system (2) can be modeled as

$$\begin{bmatrix}\dot{x}_1\\ \dot{x}_2\\ \dot{x}_3\\ \dot{x}_4\end{bmatrix} = \underbrace{\begin{bmatrix}-1 & -4 & 0 & 0\\ 1 & 0 & 0 & a\\ 1 & 0 & 0 & 0\\ 0 & -b & 0 & 0\end{bmatrix}}_{A}\begin{bmatrix}x_1\\ x_2\\ x_3\\ x_4\end{bmatrix} + \underbrace{\begin{bmatrix}0 & 0 & 0\\ 1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0\end{bmatrix}\begin{bmatrix}x_3^2\\ 1\\ 0\end{bmatrix}}_{f(x)} \tag{7}$$

$$\begin{bmatrix}\dot{y}_1\\ \dot{y}_2\\ \dot{y}_3\\ \dot{y}_4\end{bmatrix} = \underbrace{\begin{bmatrix}-1 & -4 & 0 & 0\\ 1 & 0 & 0 & a\\ 1 & 0 & 0 & 0\\ 0 & -b & 0 & 0\end{bmatrix}}_{B}\begin{bmatrix}y_1\\ y_2\\ y_3\\ y_4\end{bmatrix} + \underbrace{\begin{bmatrix}0 & 0 & 0\\ 1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0\end{bmatrix}\begin{bmatrix}y_3^2\\ 1\\ 0\end{bmatrix}}_{g(y)} + \underbrace{\begin{bmatrix}u_1\\ u_2\\ u_3\\ u_4\end{bmatrix}}_{U} \tag{8}$$

It clear that $A = B$ due to the anti-synchronization between identical system (2). Defined the error dynamics as $e_i = y_i - \alpha x_i$, where $\alpha = -1$ is scaling factor and satisfied the following condition:

$$\lim_{t\to\infty} e_i(t) = 0 \tag{9}$$

The error dynamics system yields as the following:

$$\begin{cases}\dot{e}_1 = -e_1 - 4e_2 + u_1\\ \dot{e}_2 = e_1 + ae_4 + e_3^2 - 2x_3y_3 + u_2\\ \dot{e}_3 = 2 + e_1 + u_3\\ \dot{e}_4 = -be_2 + u_4\end{cases} \tag{10}$$

Desing controller as:

$$\begin{cases}u_1 = -e_3\\ u_2 = 3e_1 - e_2 + 2x_3y_3\\ u_3 = -2 - e_3 - e_2e_3\\ u_4 = -e_4\end{cases} \tag{11}$$

Substitute controller (11) into (10) we obtain:

$$\begin{cases}\dot{e}_1 = -e_1 - 4e_2 - e_3\\ \dot{e}_2 = 4e_1 - e_2 + ae_4 + e_3^2\\ \dot{e}_3 = e_1 - e_3 - e_2e_3\\ \dot{e}_4 = -be_2 - e_4\end{cases} \tag{12}$$

Construct Lyapunov function as

$$V(e_i) = {e_i}^T P e_i \;\Rightarrow\; V(e_i) = \begin{bmatrix}e_1 & e_2 & e_3 & e_4\end{bmatrix}\underbrace{\begin{bmatrix}0.5 & 0 & 0 & 0\\ * & 0.5 & 0 & a\\ * & * & 0.5 & 0\\ * & * & * & 0.05\end{bmatrix}}_{P}\begin{bmatrix}e_1\\ e_2\\ e_3\\ e_4\end{bmatrix} \tag{13}$$

The symbol (*) which indicates symmetry in the matrix. The time derivative of the above function $V(e_i)$ gives

$$\dot{\boldsymbol{V}}(e_i) = e_1\dot{e}_1 + e_2\dot{e}_2 + e_3\dot{e}_3 + 0.2\, e_4\dot{e}_4$$

$$\dot{V}(e) = e_1(-e_1 - 4e_2 - e_3) + e_2(4e_1 - e_2 + ae_4 + e_3^2) + e_3(e_1 - e_3 - e_2e_3) + \frac{1}{10}\, e_4(-be_2 - e_4)$$

$$\dot{V}(e_i) = -e_1^2 - e_2^2 - e_3^2 - \frac{1}{10}e_4^2 = -[e_1 \quad e_2 \quad e_3 \quad e_4]\underbrace{\begin{bmatrix} 1 & 0 & 0 & 0 \\ * & 1 & 0 & 0 \\ * & * & 1 & 0 \\ * & * & * & \frac{1}{10} \end{bmatrix}}_{Q}\begin{bmatrix} e_1 \\ e_2 \\ e_3 \\ e_4 \end{bmatrix} = -e_i{}^T Q\, e_i \qquad (14)$$

where $Q = diag(1,1,1,\frac{1}{10})$, leads to $Q > 0$. Consequently, $\dot{V}(e_i) < 0$ on R^4. The controller (11) realize the anti-synchronization.

Now, the initial values as $(2,7,10,-5)$ and $(10,1,3,8)$ to illustrate the anti-synchronization that happened between (7) and (8) numerically. Figure 5. validate our theoretical results.

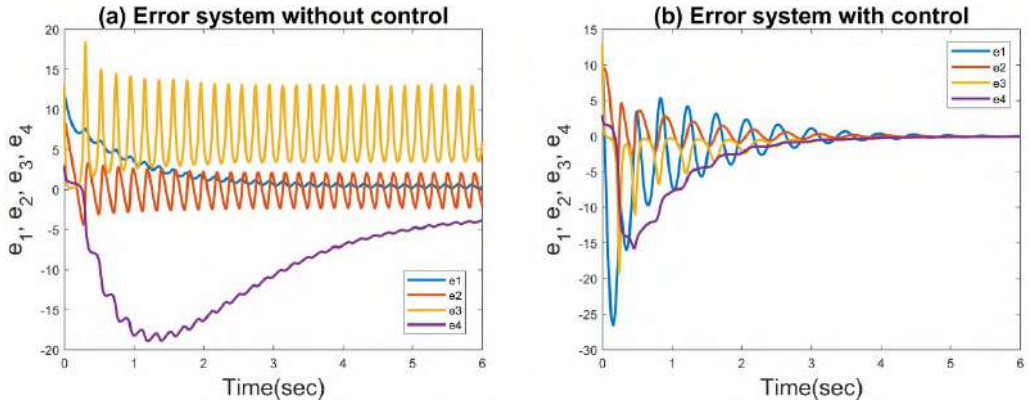

Figure 5. Anti-synchronization errors with controllers (11).

5. Conclusions

A simple 4D Sprott S system without equilibrium point and coexistence of attractors constructed from 3D Sprott-S system via a state feedback controller. This system consists of eight terms, including one constant, two parameters control, and a single quadratic nonlinear term. Besides, chaotic hidden behaviors have been discovered. Finally, anti-synchronization (AS) between two new identical systems realized via nonlinear control by using linearization and Lyapunov stability tools.

Abstract. The present study concentrates on the new generalizations of the Jordan curve theorem. In order to achieve our goal, new spaces namely PC-space and strong PC-space are defined and studied their properties. One of the main concepts that use to define the related classes of spaces is paracompact space. In addition, the property of being PC- space and strong PC-space is preserved by defining a new type of function so called para-perfect function.

1. Introduction

One of the standard results in algebraic topology is the theorem of Jordan curve" a simple closed curve C in complex plane separates the plan into two regions which are bounded and unbounded components with C the boundary of each". This theorem was first proposed in 1887 by French mathematician Camille Jordan [1]. Then, many generalizations of the Jordan curve theorem are discussed by a group of researchers. In 1990, Khalimsky et al. [2] stated a generalization in Z^2 equipped with the khalimsky topology. In 1999, Micael [3] introduced and studied J-spaces and strong J-spaces which are considered to be generalizations of properties of the Jordan curve theorem. In 2007, Gao [4] introduced the concept of LJ-spaces exploited the common generalization of Lindelöf spaces and J-spaces. In 2016, Dawood and Gasim [5] used the concept of countably compact to get many generalizations of this theorem.

In this paper, new generalizations of the Jordan curve theorem are introduced. To get these generalizations, the concept of paracompact space is used to define new spaces which are called PC - space and strong PC- space. We study the relations between the two related classes of spaces and provide some main results.

The article is formed as follows: Some basic notations are given in Section 2. The concept of PC - space and strong PC- space is introduced and studied their properties in Section 3. The paper is ended with a conclusion in Section 4.

2. Fundamental Concepts

Some fundamental concepts are reviewed to be used throughout the present study. In the sequel, all spaces are supposed to be Hausdorff.

Definition 2.1.[5] A cover $\mathcal{G} = \{\mathcal{G}_i\}_{i\in I}$ of $\mathcal{A}$ is called locally finite if, for all point $a \in \mathcal{A}$, there exists a neighbourhood intersecting only finitely many elements in $\mathcal{G}$.

Definition 2.2. [5] Let $\mathcal{G} = \{\mathcal{G}_i\}_{i\in I}$ be a cover of $\mathcal{A}$. If $\gamma = \{\gamma_j\}_{j\in J}$ is the second cover of $\mathcal{A}$, then γ is called a refinement of $\mathcal{G}$ if for each $\gamma_j \in \gamma$ there exists $\mathcal{G}_i \in \mathcal{G}$ with $\gamma_j \subseteq \mathcal{G}_i$.

Definition 2.3. [5] A topological space $\mathcal{A}$ is called paracompact if any open cover of $\mathcal{A}$ has a locally finite open refinement.

Proposition 2.4. [6] Any closed subset of a paracompact space be para-compact.

Proposition 2.5. [7] Every compact space is paracompact.
It is clear that the real number with the usual topology is paracompact space but it is not a compact space.

Proposition 2.6. [7] Every metric space is paracompact.

Proposition 2.7. [8] The image of paracompact space under a closed
and continuous function is paracompact.

Definition 2.8. [7] A space $\mathcal{A}$ is called a locally connected if for all a $\in \mathcal{A}$, and each neighbourhood $\mho$ of a there is a connected neighbourhood $\mathcal{H}$ of a where $\mathcal{H} \subset \mho$.

3. Main Results

Now, we define PC-space and strong PC-space and study their properties.
Definition 3.1. A PC- space is a topological space $\mathcal{A}$ whenever $\{\mathcal{p}, \mathcal{q}\}$ is a closed cover of $\mathcal{A}$ such that $\mathcal{p} \cap \mathcal{q}$ paracompact, then $\mathcal{p}$ or $\mathcal{q}$ is paracompact.

Definition 3.2. A space $\mathcal{A}$ is said to be strong PC- space if every paracompact $\mathcal{J} \subset \mathcal{A}$ is contained in a paracompact $\mathcal{D} \subset \mathcal{A}$ with $\mathcal{A} \setminus \mathcal{D}$ is connected.

Proposition 3.3. Any strong PC-space be a PC-space.
Proof. Assume $\mathcal{A}$ is a strong PC- space and $\mathcal{p}, \mathcal{q}$ are closed subsets of $\mathcal{A}$ with $\mathcal{p} \cap \mathcal{q}$ is paracompact and $\mathcal{A} = \mathcal{p} \cup \mathcal{q}$. So, there is a paracompact $\mathcal{D} \subset \mathcal{A}$ where $\mathcal{p} \cap \mathcal{q} \subset \mathcal{D}$ and $\mathcal{A} \setminus \mathcal{D}$ is connected. Therefore, $\{\mathcal{p} \cap (\mathcal{A} \setminus \mathcal{D}), \mathcal{q} \cap (\mathcal{A} \setminus \mathcal{D})\}$ is a disjoint closed cover of $\mathcal{A} \setminus \mathcal{D}$. However, $\mathcal{A} \setminus \mathcal{D}$ is connected, so $\mathcal{A} \setminus \mathcal{D}$ must be in $\mathcal{p} \cap (\mathcal{A} \setminus \mathcal{D})$ or in $\mathcal{q} \cap (\mathcal{A} \setminus \mathcal{D})$. Hence, $\mathcal{A} \setminus \mathcal{D} \subset \mathcal{p}$ or $\mathcal{A} \setminus \mathcal{D} \subset \mathcal{q}$. By complementation, we have $\mathcal{p}^{c} \subset \mathcal{D}$ or $\mathcal{q}^{c} \subset \mathcal{D}$, and since $\mathcal{p} \cap \mathcal{q} \subset \mathcal{D}$, so $\mathcal{p} \subset \mathcal{D}$ or $\mathcal{q} \subset \mathcal{D}$. Then $\mathcal{p}$ or $\mathcal{q}$ is paracompact by Proposition 2.1. Hence, $\mathcal{A}$ is PC-space.

Proposition 3.4. Every paracompact space be a strong PC.
Proof. Suppose the space $\mathcal{A}$ is a paracompact and $\mathcal{J} \subset \mathcal{A}$ be also paracompact, then $\mathcal{A}$ is a paracompact with $\mathcal{J} \subset \mathcal{A}$ and $\mathcal{A} \setminus \mathcal{A} = \emptyset$ is connected.

Corollary 3.5. Any paracompact space is PC- space.
Proof. The proof follows through Proposition 3.4 and Proposition 3.3.

Examples 3.6.
1- Any compact space is a strong PC.
2-Any metric space is a strong PC.
3- Any usual topology with $\mathbb{R}$ is a strong PC.
4- The indiscrete topology on any set is strong PC-space and PC-space.
5- The cofinite topology on the set of natural numbers is strong PC-space and PC-space.

Lemma 3.7. Let $\mathcal{W}$ be a closed non-paracompact set in a space $\mathcal{A}$ and $\mathcal{p} \subset \mathcal{W}$ is paracompact. Then, there is a non-paracompact closed $\mathcal{q} \subset \mathcal{W}$ such that $\mathcal{p} \cap \mathcal{q} = \emptyset$.

Proof. Assume the open cover $\mathcal{G}$ of $\mathcal{W}$ with no a locally finite open refinement, and $\mathcal{p} \subset \mathcal{W}$ is paracompact. Then, $\mathcal{p}$ has an open cover $\mathcal{G}$ and has a locally finite open refinement γ covering $\mathcal{p}$. Put $\mathcal{q} = \mathcal{W} \setminus \cup \gamma$, so $\mathcal{q}$ is closed in $\mathcal{W}$ with $\mathcal{p} \cap \mathcal{q} = \emptyset$.
Now, suppose $\mathcal{q}$ is paracompact. So, there exists a locally finite open refinement γ^* covering $\mathcal{q}$. Thus, $\mathcal{q} \subset \cup \gamma^*$and so $\mathcal{W} \setminus \cup \gamma \subset \cup \gamma^*$. That implies $\mathcal{W} \subset (\cup \gamma) \cup (\cup \gamma^*)$. However, $(\cup \gamma) \cup (\cup \gamma^*)$ is a locally finite open refinement for $\mathcal{G}$ which is contradiction. Hence, $\mathcal{q}$ is a non- paracompact.
The following theorem gives some criteria which are equivalent to be PC-spaces.

Theorem 3.8. The following statements are equivalent:
$\mathcal{A}$ is a PC-space,
For any $\mathcal{p} \subset \mathcal{A}$ with paracompact boundary, $\overline{\mathcal{p}}$ or $\overline{(\mathcal{A}\setminus\mathcal{p})}$ is para-compact,
If the closed subsets $\mathcal{p}$, $\mathcal{q}$ in $\mathcal{A}$ with $\mathcal{p} \cap \mathcal{q} = \emptyset$ and $bd(\mathcal{p})$ or $\mathrm{bd}(\mathcal{q})$ is paracompact, then $\mathcal{p}$ or $\mathcal{q}$ is paracompact.

Proof. Statement (1) implies statement (2). Suppose $\mathcal{p} \subset \mathcal{A}$ such that $\mathrm{bd}(\mathcal{p})$ is paracompact. However, we have $\mathrm{bd}(\mathcal{p}) = \overline{\mathcal{p}} \cap \overline{(\mathcal{A}\setminus\mathcal{p})}$. Thus, $\{\overline{\mathcal{p}}, \overline{(\mathcal{A}\setminus\mathcal{p})}\}$ is a closed cover of $\mathcal{A}$ with $\overline{\mathcal{p}} \cap \overline{(\mathcal{A}\setminus\mathcal{p})}$ is paracompact. Since $\mathcal{A}$ is PC-space so $\overline{\mathcal{p}}$ or $\overline{(\mathcal{A}\setminus\mathcal{p})}$ is paracompact.
Statement (2) implies statement (3). Let $\mathcal{p}$ and $\mathcal{q}$ be disjoint closed subsets of $\mathcal{A}$ with $\mathrm{bd}(\mathcal{p})$ or $\mathrm{bd}(\mathcal{q})$ is paracompact. Assume that $\mathrm{bd}(\mathcal{p})$ is aracompact, so $\overline{\mathcal{p}}$ or $\overline{(\mathcal{A}\setminus\mathcal{p})}$is paracompact by (2). However, $\mathcal{p} = \overline{\mathcal{p}}$ and $\mathcal{q} \subset (\mathcal{A}\setminus\mathcal{p}) \subset \overline{(\mathcal{A}\setminus\mathcal{p})}$. Hence, $\mathcal{p}$ or $\mathcal{q}$ is paracompact.
Statement (3) implies statement (1). We want to prove $\mathcal{A}$ is a PC-space. Assume $\{\mathcal{p}, \mathcal{q}\}$ be a closed cover of $\mathcal{A}$ where $\mathcal{p} \cap \mathcal{q}$ paracompact. Suppose that $\mathcal{q}$ is non-paracompact. Since $\mathcal{p} \cap \mathcal{q} \subset \mathcal{q}$ is a paracompact, so by lemma 3.7 there is a non- paracompact closed $\mathrm{D} \subset \mathcal{q}$ where $\mathrm{D} \cap (\mathcal{p} \cap \mathcal{q}) = \emptyset$. So, $\mathrm{D} \cap \mathcal{p} = \emptyset$. However, $\mathrm{bd}(\mathcal{p})$ is a paracompact because it is a closed subset of $\mathcal{p} \cap \mathcal{q}$. By (3) $\mathcal{p}$ or D is paracompact, but D is non- paracompact. Hence, $\mathcal{p}$ must be paracompact.

Theorem 3.9. A topological space $\mathcal{A}$ is a PC -space if and only if $\mathcal{J} \subset \mathcal{A}$ is paracompact where $\mathcal{S} = \{\mathcal{p}, \mathcal{q}\}$ is an open cover of $\mathcal{A}\setminus\mathcal{J}$ with$\mathcal{p} \cap \mathcal{q} = \emptyset$, then $\mathcal{A}\setminus \mathcal{S}_1$ or $\mathcal{A}\setminus \mathcal{S}_2$ is paracompact.

Proof. The "if" part. Assume $\mathcal{A}$ is a CP-space and a set $\mathcal{J}$ is paracompact in $\mathcal{A}$ where $\mathcal{S} = \{\mathcal{p}, \mathcal{q}\}$ is an open cover of $\mathcal{A}\setminus\mathcal{J}$ with $\cap \mathcal{q} = \emptyset$. Thus, $\{\mathcal{A}\setminus\mathcal{p}, \mathcal{A}\setminus\mathcal{q}\}$ is a closed cover of $\mathcal{A}$ with $\mathcal{A}\setminus\mathcal{p} \cap \mathcal{A}\setminus\mathcal{q} = \mathcal{A}\setminus\mathcal{p} \cup \mathcal{q}$ which is a closed set in $\mathcal{J}$ because of $\mathcal{A}\setminus\mathcal{J} \subset \mathcal{p} \cup \mathcal{q}$.Then, $\mathcal{A}\setminus\mathcal{p} \cap \mathcal{A}\setminus\mathcal{q}$ is paracompact by Proposition 2.4. However, $\mathcal{A}$ is PC-space, so $\mathcal{A}\setminus\mathcal{p}$ or $\mathcal{A}\setminus\mathcal{q}$ is paracompact.
The "only if" part. Let $\{\mathcal{p}, \mathcal{q}\}$ be a closed cover of $\mathcal{A}$ with $\mathcal{p} \cap \mathcal{q}$ is paracompact. So, $\{\mathcal{A}\setminus\mathcal{p}, \mathcal{A}\setminus\mathcal{q}\}$ is an open cover of $\mathcal{A}\setminus\mathcal{p} \cap \mathcal{q}$ with $\mathcal{A}\setminus\mathcal{p} \cap \mathcal{A}\setminus\mathcal{q} = \emptyset$. By hypothesis, $\mathcal{A}\setminus(\mathcal{A}\setminus\mathcal{p})$ or $\mathcal{A}\setminus(\mathcal{A}\setminus\mathcal{q})$ is paracompact, that is $\mathcal{p}$ or$\mathcal{q}$ is paracompact. Hence, $\mathcal{A}$ is PC-space.

Theorem 3.10. If the closed cover $\{\mathcal{A}_1, \mathcal{A}_2\}$ of a space $\mathcal{A}$ with $\mathcal{A}_1 \cap \mathcal{A}_2$ is paracompact, then $\mathcal{A}$ is a PC-space if and only if $\mathcal{A}_1$ and $\mathcal{A}_2$ are PC-spaces and $\mathcal{A}_1$ or $\mathcal{A}_2$ is paracompact.

Proof. The "if" part. Suppose that $\mathcal{A}$ is PC-space, then $\mathcal{A}_1$ or$\mathcal{A}_2$ is paracompact by definition of PC-space. Suppose that $\mathcal{A}_1$ is paracompact, it follows that $\mathcal{A}_1$ is PC-space by Corollary 3.5, now to show that $\mathcal{A}_2$ is PC-space. Let $\{\mathcal{p}, \mathcal{q}\}$ be a closed cover of $\mathcal{A}_2$ with $\mathcal{p} \cap \mathcal{q}$ is paracompact. Hence, $\mathcal{A}$ has a closed cover $\{\mathcal{p}, \mathcal{q} \cup \mathcal{A}_1\}$ where $\mathcal{p} \cap (\mathcal{q} \cup \mathcal{A}_1)$ is paracompact. So $\mathcal{p}$ or $\mathcal{q} \cup \mathcal{A}_1$ is paracompact because of $\mathcal{A}$ is PC-space. However, $\mathcal{q}$ is a closed subset of $\mathcal{q} \cup \mathcal{A}_1$, so $\mathcal{p}$ or $\mathcal{q}$ is paracompact.
The "only if" part. Assume that $\mathcal{A}_1$ and $\mathcal{A}_2$ are PC- spaces and suppose that $\mathcal{A}_2$ is paracompact, we have to show that $\mathcal{A}$ is PC-space. Let $\{\mathcal{p}, \mathcal{q}\}$ be a closed cover of $\mathcal{A}$ with $\mathcal{p} \cap \mathcal{q}$ is paracompact. Now, let $\mathcal{p}_\mathrm{i} = \mathcal{p} \cap \mathcal{A}_\mathrm{i}$ and $\mathcal{q}_\mathrm{i} = \mathcal{q} \cap \mathcal{A}_\mathrm{i}$ where $(\mathrm{i} = 1,2)$. Consequently, $\{\mathcal{p}_1, \mathcal{q}_1\}$ is a closed cover of $\mathcal{A}_1$, which is PC-space, with $\mathcal{p}_1 \cap \mathcal{q}_1 = (\mathcal{p} \cap \mathcal{A}_1) \cap (\mathcal{q} \cap \mathcal{A}_1) = (\mathcal{p} \cap \mathcal{q}) \cap \mathcal{A}_1$ which is a closed subset

of $\mathcal{P}\cap\mathcal{Q}$. Hence, $\mathcal{P}_1\cap\mathcal{Q}_1$ is paracompact and $\mathcal{P}_1$ or $\mathcal{Q}_1$ is paracompact. If $\mathcal{P}_1$ is paracompact, then $\mathcal{P} = \mathcal{P}_1\cup\mathcal{P}_2$ is paracompact since $\mathcal{P}_2$ is a closed subset of paracompact $\mathcal{A}_2$. In the same way, if $\mathcal{Q}_1$ is paracompact, then so is $\mathcal{Q}$.

Theorem 3.11. If the closed cover $\{\mathcal{A}_1, \mathcal{A}_2\}$ of a topological space $\mathcal{A}$ with $\mathcal{A}_1 \cap \mathcal{A}_2$ is paracompact. Then $\mathcal{A}$ is a strong PC-space if and only if $\mathcal{A}_1$ and $\mathcal{A}_2$ are strong PC-spaces and $\mathcal{A}_1$ or $\mathcal{A}_2$ is paracompact.

Proof. The "if" part. Assume that $\mathcal{A}$ is a strong PC-space, it follows by Proposition 3.3 that $\mathcal{A}$ is PC-space, and thus $\mathcal{A}_1$ or $\mathcal{A}_2$ is paracompact. Suppose that $\mathcal{A}_1$ is paracompact, so by Proposition 3.4 that $\mathcal{A}_1$ is strong PC-space, so it remains to show that $\mathcal{A}_2$ is strong PC-space. Let $\mathcal{J}_2 \subseteq \mathcal{A}_2$ be paracompact. Define $\mathcal{J} = \mathcal{J}_2 \cup \mathcal{A}_1$, then $\mathcal{J}$ is a paracompact subset of $\mathcal{A}$ which is a strong PC-space, so there is a paracompact closed set $\mathcal{D}$ in $\mathcal{A}$ where $\mathcal{J} \subset \mathcal{D}$ and $\mathcal{A}\backslash\mathcal{D}$ is connected. Let $\mathcal{D}_2 = \mathcal{D} \cap \mathcal{A}_2$, then $\mathcal{D}_2 \subseteq \mathcal{A}_2$ is paracompact since $\mathcal{D}_2$ is a closed subset of paracompact set $\mathcal{D}$. Also $\mathcal{J}_2 \subseteq \mathcal{D}_2$ since $\mathcal{J}_2 \subseteq \mathcal{J} \subset \mathcal{D}$ implies that $\mathcal{J}_2 \cap \mathcal{A}_2 \subset \mathcal{D} \cap \mathcal{A}_2$. Also, we note $\mathcal{A}_1 \subset \mathcal{J} \subset \mathcal{D}$ and that implies $\mathcal{A}_2\backslash\mathcal{D}_2 = \mathcal{A}\backslash\mathcal{D}$, and hens $\mathcal{A}_2\backslash\mathcal{D}_2$ is connected.
The "only if" part. Assume that $\mathcal{A}_1$ and $\mathcal{A}_2$ are strong PC-space and suppose that $\mathcal{A}_1$ is a paracompact and let $\mathcal{J} \subset \mathcal{A}$ be paracompact. Define $\mathcal{J}_2 = (\mathcal{J} \cup \mathcal{A}_1) \cap \mathcal{A}_2$, so $\mathcal{J}_2$ is paracompact since it is a closed subset of the paracompact set $\mathcal{J} \cup \mathcal{A}_1$, so $\mathcal{J}_2$ is a paracompact subset of the strong PC-space $\mathcal{A}_2$, then there is a closed paracompact subset $\mathcal{D}_2$ of $\mathcal{A}_2$ where $\mathcal{J}_2 \subseteq \mathcal{D}_2$ and $\mathcal{A}_2\backslash\mathcal{D}_2$ is connected. Now, let $\mathcal{D} = \mathcal{D}_2 \cup \mathcal{A}_1$, then $\mathcal{D}$ is a closed paracompact of $\mathcal{A}$ and $\mathcal{J} \subset \mathcal{D}$ and $\mathcal{A}\backslash\mathcal{D} = \mathcal{A}_2\backslash\mathcal{D}_2$ is connected. Hence, $\mathcal{A}$ is a strong PC-space.
Next, we introduce new types of functions that help study the preservation of strong PC-space and PC-space.

Definition 3.12. A continuous function $\mathrm{f} : \mathcal{A} \to \mathcal{B}$ is called para-perfect if it is closed and $f^{-1}(b)$ is a paracompact subset of $\mathcal{A}$ for every paracompact subset b of $\mathcal{B}$.

Definition 3.13. A closed function $\mathrm{f} : \mathcal{A} \to \mathcal{B}$ is called boundary para-perfect if the boundary of $f^{-1}(b)$ is paracompact subset of $\mathcal{A}$ for all $b \in \mathcal{B}$.

Definition 3.14. A continuous closed function $f : \mathcal{A} \to \mathcal{B}$ is called quasi- para-perfect if is $f^{-1}(b)$ is paracompact subset of $\mathcal{A}$ for all $b \in \mathcal{B}$.

Remark 3.15. It is clear that every para-perfect function is a quasi-para-perfect because it is known that the only topology that can be defined on a singleton set is the indiscrete topology. Therefore, it is paracompact and its reverse image due to the para- perfect function is paracompact.
The following proposition gives the condition of function which guarantees that the image of a PC-space is PC-space.

Proposition 3.16. If f is a closed surjective para-perfect function from a PC-space $\mathcal{A}$ to a space $\mathcal{B}$. Then $\mathcal{B}$ is PC-space.

Proof. Let $\{\mathcal{P}, \mathcal{Q}\}$ be a closed cover of $\mathcal{B}$ with $\mathcal{P}\cap\mathcal{Q}$ paracompact, then $\{\mathrm{f}^{-1}(\mathcal{P}), \mathrm{f}^{-1}(\mathcal{Q})\}$ is a cover of closed sets in $\mathcal{A}$. However, $\mathrm{f}^{-1}(\mathcal{P}\cap\mathcal{Q}) = \mathrm{f}^{-1}(\mathcal{P}) \cap \mathrm{f}^{-1}(\mathcal{Q})$ is paracompact since f is para-perfect. But $\mathcal{A}$ is PC-space, so $\mathrm{f}^{-1}(\mathcal{P})$ or $\mathrm{f}^{-1}(\mathcal{Q})$ is paracompact. So, $\mathrm{f}\left(\mathrm{f}^{-1}(\mathcal{P})\right)$ or $\mathrm{f}\left(\mathrm{f}^{-1}(\mathcal{Q})\right)$ is paracompact since f is closed and surjection function. Hence, $\mathcal{P}$ or $\mathcal{Q}$ is paracompact and then $\mathcal{B}$ is PC-space.

Proposition 3.17. If f is a closed bijective para-perfect function from a space $\mathcal{A}$ to a PC-space $\mathcal{B}$, then $\mathcal{A}$ is also PC-space.

Proof. Let $\{\mathcal{P}, \mathcal{Q}\}$ be a closed cover of $\mathcal{A}$ with $\mathcal{P}\bigcap\mathcal{Q}$ paracompact, then $\{f(\mathcal{P}), f(\mathcal{Q})\}$ is a closed cover of $\mathcal{B}$ with $f(\mathcal{P}\bigcap\mathcal{Q})$ is paracompact since f is closed bijective function. However, $f(\mathcal{P})\bigcap f(\mathcal{Q}) = f(\mathcal{P}\bigcap\mathcal{Q})$, so $(\mathcal{P})$ or $f(\mathcal{Q})$ is paracompact because of $\mathcal{B}$ is PC-space. So, $f^{-1}(f(\mathcal{P}))$ or $f^{-1}(f(\mathcal{Q}))$ is paracompact because of f is para-perfect. Hence, $\mathcal{P}$ or $\mathcal{Q}$ is paracompact. Therefore, $\mathcal{A}$ is PC-space.

Proposition 3.18. If f is a homeomorphism function and $\mathcal{A}$ be PC-space. Then $\mathcal{B}$ is also PC-space.

Proof. The proof is the same as Proposition 3.16.

Proposition 3.19. Let $f : \mathcal{A} \to \mathcal{B}$ be an open surjection para- perfect function. If $\mathcal{A}$ is a strong PC-space , then $\mathcal{B}$ is a strong PC-space.

Proof. To prove $\mathcal{B}$ is strong PC -space. let $\mathcal{J} \subset \mathcal{B}$ be a paracompact, then a set $f^{-1}(\mathcal{J})$ is a paracompact in $\mathcal{A}$ because of f is para- perfect function. However, $\mathcal{A}$ is a strong PC-space so there exist a closed paracompact $\mathcal{D} \subset \mathcal{A}$ where $f^{-1}(\mathcal{J}) \subset \mathcal{D}$ and $\mathcal{A}\backslash\mathcal{D}$ are connected. So, $f(\mathcal{D})$ is a paracompact closed set in $\mathcal{B}$ where $f(f^{-1}(\mathcal{J})) \subset f(\mathcal{D})$ and $\mathcal{B}\backslash f(\mathcal{D}) = f(\mathcal{A}\backslash\mathcal{D})$ is connected since f is continuous. However, $f(f^{-1}(\mathcal{J})) = \mathcal{J}$, so $\mathcal{J} \subset f(\mathcal{D})$ and a set $f(\mathcal{D})$ is paracompact and closed in $\mathcal{B}$ with $\mathcal{B}\backslash f(\mathcal{D})$ is connected. Hence, $\mathcal{B}$ is a strong PC-space.

Proposition 3.20. Every boundary para-perfect continuous function from a PC-space to a non-paracompact space is a quasi-para-perfect.

Proof. Assume $f : \mathcal{A} \to \mathcal{B}$ is a boundary para-perfect continuous function such that $\mathcal{A}$ is a PC-space and $\mathcal{B}$ is a non- paracompact space. To prove that f is a quasi- para-perfect, let $b \in \mathcal{B}$. Then, $f^{-1}(b)$ is a subset of $\mathcal{A}$ with paracompact boundary. From Theorem 3.8 that $\overline{f^{-1}(b)}$ or $\overline{(\mathcal{A}\backslash f^{-1}(b)}$ is paracompact. However, $\overline{(\mathcal{A}\backslash f^{-1}(b)}$ is not paracompact because of if $\overline{(\mathcal{A}\backslash f^{-1}(b)}$ is paracompact, then $\mathcal{B} = \{b\} \cup f\overline{(\mathcal{A}\backslash f^{-1}(b)}$ is paracompact, which is a contradiction. So $\overline{f^{-1}(b)}$ is paracompact, but $\overline{f^{-1}(b)} = f^{-1}(b)$. Thus f is quasi- para-perfect because of $f^{-1}(b)$ is paracompact.

Conclusion

In this study, new generalizations of the Jordan curve theorem are considered. New topological spaces namely PC -space and strong PC- space is defined to get these generalizations. Many propositions concerning these two related classes are provided. We give some criteria which are equivalent to be PC -spaces and prove that every strong PC- space is PC- space. Additionally, new functions have been defined such as the para-perfect function which is preserved the property PC -space and the property strong PC - space**.**

Discrete wavelet based estimator for the Hurst parameter of multivariate fractional Brownian motion

Discrete wavelet based estimator for the Hurst parameter of multivariate fractional Brownian motion

Munaf Yousif Hmood and Amjad Hibtallah Hamza

Department of Statistics - College of Administration and Economics - University of Baghdad, Baghdad, Iraq.

E-mail: amjad.hibtallah@uobaghdad.edu.iq

Abstract. In this paper, wavelets were used to study the multivariate fractional Brownian motion through the deviations of the random process to find an efficient estimation of Hurst exponent. The results of simulations experiments were shown that the performance of the proposed estimator was efficient. The estimation process was made by taking advantage of the detail coefficients stationarity from the wavelet transform, as the variance of this coefficient showed the power-low behavior. We use two wavelet filters (Haar and db5) to manage minimizing the mean square error of the model.

1. Introduction

In many areas such as hydrology, biology, telecommunications, and economics, the data available for analysis usually has a scaling behavior (long-memory) that needs to be discovered. The main point to detect scaling behavior is the estimation of the parameters of the models under study such as the Hurst parameter, which is used to determine self-similarity and long-range dependence. The study of these phenomena in the multidimensional case relies on fractal Gaussian noise, which is a first order incremental process

$$G_H(t) = B_H(t+1) - B_H(t) \qquad (1)$$

Where $B_H(t)$ is the fractional Brownian motion and can be generalized to be of order n and written as n-FBM. This generalization introduced by Perrin et al (2001) through the derivation of the kernel in the continuous definition of FBM.

The fractional Brownian motion can be defined as a random process characterized by non-stationary self-similarity and a stationary continuous increasing and has been used to explain many random phenomena in many areas of research and although it has demonstrated in various applications, for example bone radiographs.

More recently, wavelet transformation has emerged as a powerful mathematical tool for signal processing by setting a timescale.

Wavelets give a new look to the statistical analysis of random processes, as wavelets rules in the time scale plan provide a suitable framework for representing functions with sharp spikes and analyzing them with good accuracy and allow studying basic characteristics such as long-memory, self-similarity and stationary increasing.

The objective of this paper is to develop a method that can be used to model and study nth order fractional Brownian motion through wavelet lens by estimating the Hurst parameter. The proposed procedure will rely on finding an unbiased estimate of the difference in the Gaussian noise of the

fractional Brownian motion using Haar and Daubechies 5 (db5) wavelet. The performance of this estimator was validated through a simulation study.

The paper is structured as follow: Section 2 we give an overview of discrete wavelet transform, in Section 3 the fractional Brownian motion properties will be presented, and in Section 4 the proposed method will be briefed, Section 5 the simulation study will be conducted and finally Section 6 the conclusions will be explain.

2. Discrete Wavelets Transform

The main problem in the early 1980s when working with wavelet was to create a multiresolution analysis where the scale function had compact and continuous support. In her paper that published in 1988, Daubechies found a way to build a multiresolution, continuous, orthonormal and compact support scale function that attracted the attention of researchers interested in the wavelet field at that time, and here we introduce the DWT beginning with wavelet function $\psi(t), t \in \mathbb{R}$ such that [1]:

$$\int \psi(t)\, dt = 0 \qquad (2)$$

Where this condition satisfy some integrability conditions, $\psi \in L_1(\mathbb{R}) \cap L_2(\mathbb{R})$. Which require the wavelet to be bounded, centered around the origin, and have time and frequency support. Where it is finite or decreases very fast. Time and frequency concertation are restricted by the Gabor-Heisenberg uncertainty principal. A wavelet ψ have N zero moments (vanishing moment) if: [3]

$$\int t^k \psi(t)\, dt = 0, k = 0,1, \dots, N-1 \qquad (3)$$

Where N is an integer at least equal 1. The increase in the vanishing moments give an enlargement in the time support but bring smoothness, continuity, derivability and more concentration of the spectral in a given frequency v_0. An example of wavelet have derivative of standard normal density is the Haar wavelet and the Daubechies wavelet, where both constructed from multiresolution analysis (MRA), and also the Mexican hat wavelet which is the 2nd derivative of the normal function and has 2 vanishing moments.

The Daubechies wavelets constitute a family of wavelets indexed by their vanishing moments and give rise to the orthonormal basis. The Haar wavelet is a special case of both the Daubechies and spline families that has one vanishing moment and has finite time support. The wavelet coefficients are equivalent to the increments of the process, and can be defined beginning from the function:

$$\psi_{j,k}(t) = 2^{-\frac{j}{2}} \psi\left(2^{-j}t - k\right), \quad j,k \in \mathbb{Z} \qquad (4)$$

Where j, k are dilation and translation of ψ respectively.

$$\int \psi_{j,k}^2(t)dt = \int \psi^2(t)dt \qquad (5)$$

It allows the $L^2(\mathbb{R})$ norm to be preserved. Using the functions $\{\psi_{j,k}, j,k \in \mathbb{Z}\}$as a set of filters we can now define the DWT of a function $\{X(t), t \in \mathbb{R}\}$ as:

$$d_{j,k} = \int X(t)\, \psi_{j,k}(t)dt \qquad (6)$$

Where the $d_{j,k}$ are the wavelet coefficients called details, as it encode the differential information between adjacent scales centered about 2^j, and the time $2^j k$. The details sometimes written as $d_X(j,k)$to emphasize that they correspond to X. The adjective discrete in DWT refers to the fact the indices j,k take discrete values in contrast to the CWT where they take real values.

Multiresolution analysis is a specific class of wavelets which is of particular interest because it has potentially stronger mathematical properties and because it gives birth to fast recursive pyramidal decomposition algorithms. Their key properties is

i- The number of zero moments, regularity, time or frequency support, can be easily and flexibly tuned.
ii- Fast pyramidal algorithms to compute the wavelet coefficients.

The construction of such wavelets of which the Daubechies and spline families are famous examples is integral to the so called the multiresolution analysis theory. The dilation equation for the Daubechies scale function can be written as [1]:

$$\phi(\mathrm{t}) = 2^{-j/2} \sum_{k\in\mathbb{Z}} h_k \phi(2^{-j}t - k) \qquad (7)$$

Where h_k is a scale filter and also called the average block and now if we had a multiresolution analysis and had h_k real values from dilation equation then h_k have the following properties:

1. $\sum_{\mathrm{k}\in\mathbb{Z}} \mathrm{h_k} = 2^{1/2}$ (8)
2. $\sum_{\mathrm{k}\in\mathbb{Z}} \mathrm{h_k^2} = 1$

There is a great benefit to this filter in calculating the projection coefficients according to the following equation:

$$b_\ell = \sum_{k\in\mathbb{Z}} a_k h_{k-2\ell} \ , where\ k, \ell \in \mathbb{Z} \qquad (9)$$

Where a_k are the approximation coefficients. The dilation equation for the wavelet function is the same as the formula of the scale function's dilation equation, but in terms of wavelet filter as follows:

$$\psi(\mathrm{t}) = 2^{-j/2} \sum_{k\in\mathbb{Z}} g_k \phi(2^{-j}t - k) \qquad (10)$$

It should also be noted that the value of the wavelet filter can be calculated through the scale filter.

$$g_k = (-1)^k h_{k-1} \qquad (11)$$

3. Fractional Brownian Motion

Fractional Brownian motion (FBM) is a centered stochastic Gaussian process. Mandelbrot & Van Ness [2] called it Brownian, and to define it they use different fractional integral of white noise:

$$B_H(t) = B_H(0) + \frac{1}{\Gamma(H+\frac{1}{2})}\left\{\int_{-\infty}^{0}\left[(t-s)^{H-1/2} - (-s)^{H-1/2}\right]dB_s + \int_0^t (t-s)^{H-1/2} dB_s\right\} \quad (12)$$

The most important difference between Brownian motion and fractional Brownian motion is in the increments so in the classic process the increments are independent but in fractional Brownian motion (FBM) are not, when $H > 1/2$ there is positive autocorrelation on other hand if $H < 1/2$ the autocorrelation is negative.

Fractional Brownian motion has zero mean and variance covariance equal to [3]:

$$E[B_H(t)B_H(s)] = \frac{1}{2}\left(|t|^{2H} + |s|^{2H} - |t-s|^{2H}\right) \quad (13)$$

Where H is a Hurst parameter which was defined by both Mandelbrot and Van Ness and its value ranges between [0, 1] and shows the extent of roughness of the movement, as its value increase softer the signal become so the type of the random process is related to the value of this parameter.

The existence of the fractional Brownian motion comes from the presence of the centered Gaussian process. If we assume that there is a real parameter $H > 0$, then there is a continuous central Gaussian process $B_H = (B_t^H)_{t\geq 0}$ with a known positive variance if and only if $H \leq 1$. [4]
The main properties of fractional Brownian motion is:

1. Self-similarity is visually seen as the same pattern repeating both seen up close and seen from a far. In other words, there are small versions of the larger pattern repeated inside larger patterns. This property of a random process is achieved if:

$$B_H(at) \sim |a|^H B_H(t) \quad (14)$$

This property is due to the fact that the covariance function is homogeneous of order 2H, which gives the process a fractional character.

2. Stationary increments which satisfied when:

$$B_H(t) - B_H(s) \sim B_H(t-s) \quad (15)$$

3. Long-range dependence or the long memory is a phenomenon that appears in the analysis of time-related data and expresses the slow exponential decay of the autocorrelation coefficient and its appear clearly in fBm when $H > 1/2$.

$$\sum_{n=1}^{\infty} E\left[B_H(1)\big(B_H(n+1) - B_H(n)\big)\right] = \infty \quad (16)$$

4. Regularity where the sample-paths are non-derivative at almost every point, i.e., all trajectories are locally Holder continuous for any function have d-dimensional Euclidian space is Holder continuous when there is a positive constant C and $\alpha > 0$ such that $|f(x) - f(y)| \leq C|x-y|^{\alpha}$ That is, for each trajectory path, for each T> 0, and for each $\varepsilon > 0$, there is a constant value of C so that:

$$|B_H(t) - B_H(s)| \leq C|t-s|^{H-\varepsilon} \quad (17)$$

5. Semi-Martingale in the theory of probability, Martingale is a series of random variables (any random process) so that at any time the conditional expectation of the present value excluding all previous values is equal to the first value.

$$E[X_{n+1}|X_1, \ldots\ldots, X_n] = X_n \quad (18)$$

This property occur in many random processes such as classic Brownian motion i.e. when H = ½. It's so obvious so it should be that this property is not realized in the case of fractional Brownian motion because the covariance of this type not equal to zero and many researchers have demonstrated this property when H> 1/2 and when H <1/2.

4. Second Moment of Gaussian Noise using Wavelet (SMGNW)

The analysis of the fractional Brownian motion depends on the estimation of the Hurst parameter, which is sometimes called the parameter of roughness. The difficulty in the estimation process lies in the nonstationary and the fact that this type of random process is Locally Holder Continuous, that is, it does not have a derivative at almost every point.

This topic has raised the interest of many researchers, and here in this paper, we find a more efficient way to conduct this work. It was relied on finding an unbiased estimate of the difference in the Gaussian noise of the fractional Brownian motion using wavelets, which proved effective in improving the estimator's efficiency and its approach to the real value too close and the error is relatively too low, here we will be discuss in detail. Beginning with the definition of wavelet function.

$$\psi_{j,k}(t) = 2^{-\frac{j}{2}}\psi\left(2^{-j}t - k\right), j, k \in \mathbb{Z} \quad (19)$$

Thus, the details coefficients for the transformation can be defined as

$$d_{j,k} = \int_{\mathbb{R}} X(t)\psi_{j,k}(t)dt \quad (20)$$

Where $d_{j,k}$ can be calculated from $d_{j-1,k}$ as follow [13]

$$\begin{aligned} d_{j,k} &= \int_{\mathbb{R}} X(t)2^{-\frac{j}{2}}\psi\left(2^{-j}t - k\right)dt \\ &= \int_{\mathbb{R}} X(t)2^{-\frac{j}{2}}\sqrt{2}\sum\nolimits_n v_n\psi(2\left(2^{-j}t - k\right) - n)\,dt \\ &= \sum\nolimits_n v_n \int_{\mathbb{R}} X(t)2^{\frac{-j+1}{2}}\,\psi\left(2^{-j+1}t - 2k - n\right)dt \\ d_{j,k} &= \textstyle\sum_n v_n d_{j-1,2k+n} \end{aligned} \quad (21)$$

These coefficients are characterized by not being affected by the polynomials due to the vanishing moments and their stationary, and this is evident when fix the scale. We will notice that the translation is not affected by the increases
At the scale s and the assumed increase of translation by the value of r [5]

$$d_{s,k+r} = \int_{\mathbb{R}} X(t)\psi(t - k - r)dt$$

Let $u = t - r$ then $t = u + r$

$$= \int_{\mathbb{R}} X(u + r)\,\psi(u - k)du$$

$$= \int_{\mathbb{R}} [X(u + r) - \mathrm{X}(r)]\,\psi(u - k)du$$

At $r = 0$

$$\cong \int_{\mathbb{R}} [X(u) - \mathrm{X}(0)]\,\psi(u - k)du$$

$$= \int_{\mathbb{R}} X(u)\,\psi(u - k)du = d_{s,k} \quad (22)$$

The third step was achieved through one of the main characteristics of the wavelets, which is $\int_{\mathbb{R}} \psi(u)du = 0$. The fourth step was achieved by approximate the integration by sum and taking advantage of the stationary increasing. These characteristics of the detail parameters make it able to give accurate estimates even in signals of self-similar and stationary increases by finding an unbiased value for the variance of these coefficients, and that the value of this variation can be calculated using the definition of variance of the process knowing that fBm has zero mean

$$\mathrm{var}(d_{j,k}) = E(d_{j,k})^2 = \frac{1}{n}\sum_{k=1}^{n}|d_{j,k}|^2 \quad (23)$$

Istas [6] and Abry [5] have indicated a bias in this amount. However, it is possible to reduce it through the wavelet transformation through its previously mentioned characteristics.

The problem is the choosing of a wavelet with a sufficient number of vanishing moments to smooth the signal without increasing the estimator bias, but enough so does not increase the variance of the estimate.

For this reason, we have found that using two wavelets would be the best way to adjust the amount of variance without increasing the estimate bias or the variance.

The db 5 wavelet and the Haar wavelet were used separately to perform the transformation of the series after taking the differences to it and find the Gaussian noise in the series as follows:

$$G_H(t_j) = B_H(t_j) - B_H(t_{j-1}) \quad (24)$$

Now filtration will be made to the differences using the wavelet filter c

$$\begin{aligned} d_{1,.} &= [c * (g_1, g_2, g_3, \dots, g_p)], \quad p = length\ of\ c \\ d_{2,.} &= [c * (g_2, g_3, g_4, \dots, g_{p+1})] \\ d_{3,.} &= [c * (g_3, g_4, g_5, \dots, g_{p+2})] \\ d_{n,.} &= [c * (g_{n-p+1}, g_{n-p+2}, g_{n-p+3}, \dots, g_n)], \quad n = length\ of\ G \end{aligned} \quad (25)$$

The transformation has been made, Flandrin [7] has discussed and appointed out that the approximation coefficients are strongly correlated, but on the other hand, there is independency in the detail coefficient values that can be adopted in calculating an unbiased estimate of the Hurst parameter, and so the value of variance is as follows:

$$E(d_{j,k})^2 = E(d_{0,0})^2 2^{j(2H+1)} \quad (26)$$

Where $E(d_{0,0})^2$ is a constant, as shown by Houdre [8] the logarithms of the variance will give an estimate for the Hurst parameter

$$\log_2\left(E(d_{j,k})^2\right) = (2H+1)j + \log_2(E(d_{0,0})^2) \quad (27)$$

Where j will be a linear function (j represents the courser level) and the slope of this function will be an estimate of H, but it will be a biased estimate. For eliminating this bias, Istats [6] find out using quadratic variation that dividing two filtered variances by using different bands will give an unbiased estimate for the variance, for this purpose we use Haar and db 5 wavelet to find an unbiased estimate for the variance of detail coefficients

$$\mathrm{V}_1 = \frac{var(d_{j,k})_{half\ band\ Haar}}{var(d_{j,k})_{Haar}} \quad and\ \mathrm{V}_2 = \frac{var(d_{j,k})_{half\ band\ db\ 5}}{var(d_{j,k})_{db\ 5}}$$
$$V = \frac{1}{2}(V_1 + V_2) \quad (28)$$

Where the half band coefficients can be defined as follow

$$(d_{j,k})_{halfband} = [d_1, 0, d_2, 0, d_3, 0, \dots\dots\dots] \quad (29)$$

From the mentioned relations the estimate can be found using the following expression

$$\widehat{\mathrm{H}} = \frac{1}{2}\, log_2(V) \qquad (30)$$

5. Simulation study

In this section, we will conduct simulation experiments of multivariate fractional Brownian motion, where wavelet synthesis method proposed by Sellan, Mayer and Abry [9] [10] will be used for generating the mentioned random process, and then we will use Second moment of Gaussian noise using wavelet (SMGNW). The length of the series to be generated will be as $n = 100{,}200$ and the number of variables $m = 4, 8, 12$ we will repeat the process with $rep = 500$ for the sake of increasing the accuracy in the estimation process. As for the wavelet used for the generation, $s = 2^{10}, 2^{12}$. Taking into account that the estimation process for the Hurst parameter will be for all levels $H = [0.1: 0.9]$. The mean square error and the bias of the estimator will be calculated as follows

$$MSE(\widehat{H}) = Var(\widehat{H}) + Bias^2(\widehat{H})$$
$$= \left(\frac{1}{4}\sum_j \sigma_j^2 \theta_j^2\right) + (\widehat{H} - H)^2$$

Where $\theta_j = \frac{\sum(S*j - S_j)/\sigma_j^2}{S\, S_{jj} - S_j^2}$, *and* $S = \sum \frac{1}{\sigma_j^2}, S_j = \sum \frac{j}{\sigma_j^2}, S_{jj} = \sum \frac{j^2}{\sigma_j^2}$

$$Var(y_j) = \sigma_j^2 = \frac{\varsigma\left(2, \frac{N_j}{2}\right)}{ln^2(2)}, E(y_j) = 2(H+1) + constant \qquad (31)$$

Where $\varsigma\left(2, \frac{\mathrm{N_j}}{2}\right)$ is a generalized Riemann Zeta function [11]

Also, a new random series will be generated each time before the estimation in order to get the best view of the performance of the method used and at different levels of the random process.

6. Conclusions

The estimation methods for signals with long memory, non-stationary often suffer from bias in the model variance that usually used for estimation, which in turn affects the error in the model estimation. In the SMGNW method used above, we consider reducing the amount of bias by truncating a part equal to the length of the filter used for the transformation, which led to the reduction of this bias to lower levels. The results of this truncation affected the estimation process positively. In this method, we also adopted the half-band method, which contributed in elimination of unwanted noise to obtain an efficient

estimator. Also, by relying on wavelet filters to perform the estimation process, the linear effect of the model was excluded from the model through the vanishing moments, which is one of the most important properties of the wavelet. The uses of Haar and db5 wavelet filters made our estimator better than other methods that's because we rely on denoising twice which make the signal smoother. This procedure made the proposed estimation process an efficient method for all levels of estimation through mean square error and bias as is evident from the results obtained.

Signal Soft Topology and Molecules of Matter

Signal Soft Topology and Molecules of Matter

Majd Hamid Mahmood

Department of Mathematics, College of Education, University of Al-Mustansiriyah, Baghdad, Iraq

E-mail: mgmg227@yahoo.com

Abstract. In this search, we will make modeling for molecules of matter (organic, inorganic) by using signal soft sets, and generate signal soft topologies for molecules.

1. Introduction

Molodtsov in [4] defines a soft set as a general mathematical tool for dealing with uncertain objects. Mahmood in [3] presented a signal soft set to represent atom groups, electron, proton, neutron, anti - atom, we define operations on signal soft sets to study the construction of some chemical compounds like water hydrochloric acid, define a signal soft topology, in this search we will make modeling for molecules of matter by using a signal soft sets, generate signal soft topology for molecules.

2. Basics on soft set and atoms

In this section, we will define the signal soft element, signal soft set to make a model for the atom, molecules define $\oplus,\ominus$ between signal soft sets, with examples.

Definition 2.1 [3]: Let X be a universal set contain elements in R^+ denoted by "h", E is a set of parameters contain elements denoted by "e " .Then, the signal soft element x defined by:
$x = \{ (e_i , h_j^{\delta ij}) = (e_i , \digamma(ei)) : \digamma : E \to h_j^{\delta ij} , h_j \in P(X) , \delta_{ij}$ take + , – , ± or $\mp$ signal
$\forall i, j \in \Omega$, Ω is indexed set of natural numbers}.

Definition 2.2 [3]: Let X be a universal set of "h" elements in R^+, E is a set of parameters of "e" elements.Then, the signal soft set defined by : $N = (\digamma,E) = \{ x : x = (e_i, h_j^{\delta ij}), \delta_{ij}$ take ("+" for proton and anti-electron , " – " for electron and anti - proton , " ± " for neutron , "$\mp$" for anti-neutron) ,$\forall$ i , j$\in$ Ω , Ω is indexed set of natural numbers }.

Model 2.3 [3]: Let N be the atom name; η, ρ, ε denoted respectively to neutron, proton, electron and δ for the signal. Then, the atom as a signal soft set model is defined by $N = (N, \eta^\delta , \rho^\delta, \varepsilon^\delta)$.

Coding 2.4 [3]: As a special case of the atom, we have the followings:
1- Neutron = $\eta = (\emptyset , 1^{\pm} , 0^{+} , 0^{-})$.
2- Proton = $\rho = (\emptyset , 0^{\pm}, 1^{+} , 0^{-})$.
3- Electron = $\varepsilon = (\emptyset , 0^{\pm}, 0^{+}, 1^{-})$.
4- Energy = $\xi = (\emptyset , 0^{\pm} , 0^{+} , 0^{-}) = \Phi$.

Examples 2.5 [3]:
1- Hydrogen = (H, $0^{\pm}$, $1^{+,1-}$).
2- Oxygen = (O, $8^{\pm}$, 8^{+}, 8^{-}).
3- Carbon = (C, $6^{\pm}$, 6^{+}, 6^{-}).
4- Nitrogen = (N, $7^{\pm}$, 7^{+}, 7^{-}).

Definition 2.6 [3]: Let X be a universal set of "*h*" elements in R^{+},E be a set of parameters of "*e*" elements. Then, the null-signal soft set denoted by: $\Phi = \{x : x = (e_i, h_j^{\delta ij})$, $\forall$ i , j $\in \Omega$, Ω is indexed set of natural numbers, $e_i = \emptyset$ and $h_j = 0$, δ ij take + , – , $\pm$ or $\mp$ signal }.

Example 2.7 [3]: X = { $h_1 = h_2 = h_3 = 0$ }, E = { $e_1 = \emptyset$ } , $\Phi = (\emptyset , 0^{\pm} , 0^{+} , 0^{-})$ is a null-signal soft set, there are three signal soft elements x_1, x_2, x_3 :
$x_1 = (e_1, h_1^{\delta 11}) = (\emptyset , 0^{\pm})$, $x_2 = (e_1, h_2^{\delta 12}) = (\emptyset , 0^{+})$, $x_3 = (e_1, h_3^{\delta 13}) = (\emptyset , 0^{-})$.

Definition 2.8 [3]: Let X be a universal set of "*h*" elements in R^{+} , E be a set of parameters of "*e*" elements and (F,E) be a soft set .Then, the universal signal soft set denoted by : U = $\{x : x = (e_i, h_j^{\delta ij})$,$\forall$ i , j $\in \Omega$, Ω is indexed set of natural numbers, e_i = X and $h_j = \infty$, ∞ is the most large number in X}.

Example 2.9[3]: X = { $h_1 = h_2 = h_3 = \infty$ } , E = { e_1 = X } , U = (X , $\infty^{\pm}$, ∞^{+} , ∞^{-}) is a universal signal soft set there are three signal soft elements x_1, x_2, x_3 :
$x_1 = (e_1, h_1^{\delta 11}) = (X, \infty^{\pm})$, $x_2 = (e_1, h_2^{\delta 12}) = (X , \infty^{+})$, $x_3 = (e_1, h_3^{\delta 13}) = (X , \infty^{-})$.

Remark 2.10 [3] The null-signal soft set and the universal signal soft set are virtual sets.

Definition 2.11[3]: Let N = { $x : x = (e_i, hj^{\delta ij})$ } .The complement of the Signal soft set N denoted by: N^{c} ={ $x^{c} : x^{c} = (e_i, hj^{-\delta ij})$ } .

Definition 2.12 [3]: Let N_1, N_2 be two signal soft sets.Then, N_1 is a subset of N_2, if each $x_{\alpha} \in N_1$ we have $x_{\alpha} \in N_2$ and denoted by $N_1 \subseteq N_2$.

Definition 2.13[3]: The two signal soft sets N_1, N_2 are equal if $N_1 \subseteq N_2 \wedge N_2 \subseteq N_1$, denoted by $N_1 = N_2$ otherwise $N_1 \neq N_2$.

Definition 2.14 [3]: Let $N_1 = (N_1 , \eta_1^{\delta 1}, \rho_1^{\delta 2}, \varepsilon_1^{\delta 3})$, $N_2 = (N_2 , \eta_2^{\sigma 1}, \rho_2^{\sigma 2} , \varepsilon_2^{\sigma 3})$ be two signal soft sets. Then, the summation is defined as follow:
$N_1 \oplus N_2 = (N_1 , \eta_1^{\delta 1} , \rho_1^{\delta 2}, \varepsilon_1^{\delta 3}) \oplus (N_2 , \eta_2^{\sigma 1} , \rho_2^{\sigma 2} , \varepsilon_2^{\sigma 3})$
$= N_3 = (N_3 , \eta_1^{\delta 1} + \eta_2^{\sigma 1} , \rho_1^{\delta 2} + \rho_2^{\sigma 2} , \varepsilon_1^{\delta 3} + \varepsilon_2^{\sigma 3})$.

Remark 2.15: Let N_{be} a signal soft set. Then, the summation of *n* signal soft sets of N is *n* N.

Definition 2.16 [3]: Let $N_1 = (N_1 , \eta_1^{\delta 1}, \rho_1^{\delta 2}, \varepsilon_1^{\delta 3})$, $N_2 = (N_2 , \eta_2^{\sigma 1}, \rho_2^{\sigma 2} , \varepsilon_2^{\sigma 3})$ be two signal soft sets. Then, the difference is defined as follow:
$N_1 \ominus N_2 = (N_1 , \eta_1^{\delta 1} , \rho_1^{\delta 2}, \varepsilon_1^{\delta 3}) \ominus (N_2 , \eta_2^{\sigma 1} , \rho_2^{\sigma 2} , \varepsilon_2^{\sigma 3})$
$= N_3 = (N_3 , \eta_1^{\delta 1} - \eta_2^{\sigma 1} , \rho_1^{\delta 2} - \rho_2^{\sigma 2} , \varepsilon_1^{\delta 3} - \varepsilon_2^{\sigma 3})$.

Notice 2.17 [3]: In general
$(N_1 , \eta_1^{\delta 1} , \rho_1^{\delta 2}, \varepsilon_1^{\delta 3}) \oplus (N_2 , \eta_2^{\sigma 1} , \rho_2^{\sigma 2} , \varepsilon_2^{\sigma 3}) = (N_3 , \eta_3^{\kappa 1} , \rho_3^{\kappa 2} , \varepsilon_3^{\kappa 3}) \circledast \xi$

(N_1, $\eta_1^{\delta 1}$, $\rho_1^{\delta 2}$, $\varepsilon_1^{\delta 3}$) $\ominus$ (N_2 , $\eta_2^{\sigma 1}$, $\rho_2^{\sigma 2}$, $\varepsilon_2^{\sigma 3}$) = (N_3 , $\eta_3^{\kappa 1}$, $\rho_3^{\kappa 2}$, $\varepsilon_3^{\kappa 3}$) $\oplus\!\!\!\!\ominus$ ξ
where ξ = (N_4 , $\eta_4^{\gamma 1}$, $\rho_4^{\gamma 2}$, $\varepsilon_4^{\gamma 3}$) could be an atom, neutron, proton, electron, Φ, anti-atom, anti-energy, or PE (as seen in the next sections).

Definition 2. 18: Let N_1 = (N_1, $\eta_1^{\delta 1}$, $\rho_1^{\delta 2}$, $\varepsilon_1^{\delta 3}$), N_2 = (N_2 , $\eta_2^{\sigma 1}$, $\rho_2^{\sigma 2}$, $\varepsilon_2^{\sigma 3}$) , ….. N_n = (N_n , $\eta_n^{\alpha 1}$, $\rho_n^{\alpha 2}$, $\varepsilon_n^{\alpha 3}$) are signal soft sets (atoms) . Their summation is a (molecular M) defined as follow:
$N_1 \oplus N_2 \oplus ... \oplus N_n$ = (N_1 , $\eta_1^{\delta 1}$, $\rho_1^{\delta 2}$, $\varepsilon_1^{\delta 3}$) $\oplus$ (N_2 , $\eta_2^{\sigma 1}$,$\rho_2^{\sigma 2}$, $\varepsilon_2^{\sigma 3}$) $\oplus$ ... $\oplus$ (N_n , $\eta_n^{\alpha 1}$, $\rho_n^{\alpha 2}$, $\varepsilon_n^{\alpha 3}$)
= M = (N , $\eta_1^{\delta 1}$ + $\eta_2^{\sigma 1}$ +…+ $\eta_n^{\alpha 1}$, $\rho_1^{\delta 2}$ + $\rho_2^{\sigma 2}$ +…+$\rho_n^{\alpha 2}$, $\varepsilon_1^{\delta 3}$ + $\varepsilon_2^{\sigma 3}$ +…+$\varepsilon_n^{\alpha 3}$).

Remarks 2.19:
1- The molecular M could be a set of summation of other molecules M_1, M_2, ..., M_n :
$M = M_1 \oplus M_2 \oplus ... \oplus M_n$
or summation of atoms N_1 , N_2 , ... , N_n :
$M = N_1 \oplus N_2 \oplus ... \oplus N_n$
or summation of both molecules and atoms M_1 , M_2 , ... ,M_n , N_1 , N_2 , ... , N_n :
$M = M_1 \oplus M_2 \oplus ... \oplus M_n \oplus N_1 \oplus N_2 \oplus ... \oplus N_n$
2- The molecular M is a (subcollection) of some compound set C if M is a summation of arbitrary many atoms (or molecules or both) in C,
i.e. $M \subset C \Leftrightarrow \forall\, C = N_1 \oplus N_2 \oplus \cdots \oplus N_n$, $M = \oplus N_{\alpha i}$ for some $\alpha i \in I$, I = 1 , 2 , …., n .

3- Chemical (organic) molecules modeled by a signal soft set

In this section, we will study some basic types of organic molecules represented as a signal soft set, first, we will study the basics types like amino acids the construction of DNA and RNA then we will study the representation of some types of carbohydrates, fats, and protein.

Examples 3.1: This example show the basic types of amino acids that contained in the DNA and RNA represented as signal soft sets.
1- Cytosine C4H5N3O " $\mathcal{C}$ "
Let M_1 = (C,$6^{\pm}$,6^{+},6^{-}) $\oplus$ (C,$6^{\pm}$,6^{+},6^{-}) $\oplus$ (C,$6^{\pm}$,6^{+},6^{-}) $\oplus$ (C,$6^{\pm}$,6^{+},6^{-})
= 4(C, $6^{\pm}$,6^{+},6^{-}) = (C_4, $24^{\pm}$,24^{+},24^{-}) ,
M_2 = (H,$0^{\pm}$,1^{+},1^{-}) $\oplus$ (H,$0^{\pm}$,1^{+},1^{-}) $\oplus$ (H,$0^{\pm}$,1^{+},1^{-}) $\oplus$ (H,$0^{\pm}$,1^{+},1^{-}) $\oplus$ (H,$0^{\pm}$,1^{+},1^{-})
= 5(H,$0^{\pm}$,1^{+},1^{-}) = (H_5,$0^{\pm}$,5^{+},5^{-}),
M_3 = (N,$7^{\pm}$,7^{+},7^{-}) $\oplus$ (N,$7^{\pm}$,7^{+},7^{-}) $\oplus$ (N,$7^{\pm}$,7^{+},7^{-}) = 3 (N,$7^{\pm}$,7^{+},7^{-}) = (N_3,$21^{\pm}$,21^{+},21^{-})
N_4 = Oxygen = (O,$8^{\pm}$,8^{+},8^{-}) .
Then, the Cytosine = $M_1 \oplus M_2 \oplus M_3 \oplus N_4$
= (C_4, $24^{\pm}$,24^{+},24^{-}) $\oplus$ (H_5,$0^{\pm}$,5^{+},5^{-}) $\oplus$ (N_3,$21^{\pm}$,21^{+},21^{-}) $\oplus$ (O,$8^{\pm}$,8^{+},8^{-}) = ($\mathcal{C}$, $53^{\pm}$, 58^{+} , 58^{-})
2- Guanine C5H5N5O " $\mathcal{G}$ "
Let M_1 = 5(C,$6^{\pm}$,6^{+},6^{-}) = (C_5, $30^{\pm}$,30^{+},30^{-}),
M_2 = 5(H,$0^{\pm}$,1^{+},1^{-}) = (H_5,$0^{\pm}$,5^{+},5^{-}) ,
M_3= 5(N,$7^{\pm}$,7^{+},7^{-}) = (N_5,$35^{\pm}$,35^{+},35^{-})
N_4 = Oxygen = (O,$8^{\pm}$,8^{+},8^{-}) .Then, the Guanine = $M_1 \oplus M_2 \oplus M_3 \oplus N_4$
= (C_5, $30^{\pm}$,30^{+},30^{-}) $\oplus$ (H_5,$0^{\pm}$,5^{+},5^{-}) $\oplus$ (N_5,$35^{\pm}$,35^{+},35^{-}) $\oplus$ (O,$8^{\pm}$,8^{+},8^{-})
= (, $73^{\pm}$, 78^{+} , 78^{-}).
3- Adenine C5H5N5 " $\mathcal{A}$ "
Let M_1 = 5(C,$6^{\pm}$,6^{+},6^{-}) = (C_5, $30^{\pm}$,30^{+},30^{-}) , M_2 = 5(H,$0^{\pm}$,1^{+},1^{-}) = (H_5,$0^{\pm}$,5^{+},5^{-})
M_3= 5(N,$7^{\pm}$,7^{+},7^{-}) = (N_5,$35^{\pm}$,35^{+},35^{-}) .
Then, the Adenine = $M_1 \oplus M_2 \oplus M_3$ = (C_5, $30^{\pm}$,30^{+},30^{-}) $\oplus$ (H_5,$0^{\pm}$,5^{+},5^{-}) $\oplus$ (N_5,$35^{\pm}$,35^{+},35^{-})
= (, $65^{\pm}$, 70^{+} , 70^{-}) .
4- Thymine C5H6N2O2 " $\mathcal{T}$ "

Let $M_1 = 5(C,6^{\pm},6^{+},6^{-}) = (C_5, 30^{\pm},30^{+},30^{-})$,
$M_2 = 6(H,0^{\pm},1^{+},1^{-}) = (H_6,0^{\pm},6^{+},6^{-})$
$M_3 = 2(N,7^{\pm},7^{+},7^{-}) = (N_2,14^{\pm},14^{+},14^{-})$
$M_4 = 2(O,8^{\pm},8^{+},8^{-}) = (O_2,16^{\pm},16^{+},16^{-})$.
Then the Thymine = $M_1 \oplus M_2 \oplus M_3 \oplus M_4$
$= (C_5, 30^{\pm},30^{+},30^{-}) \oplus (H_6,0^{\pm},6^{+},6^{-}) \oplus (N_2,14^{\pm},14^{+},14^{-}) \oplus (O_2,16^{\pm},16^{+},16^{-})$
$= (, 60^{\pm} , 66^{+} , 66^{-})$.

Example 3.2: In this example we will make a model for Fructose which is a simple kind of Carbohydrate
Fructose = C6H12O6 " "
Let $M_1 = 6(C,6^{\pm},6^{+},6^{-}) = (C_6, 36^{\pm},36^{+},36^{-})$, $M_2 = 12(H,0^{\pm},1^{+},1^{-}) = (H_{12},0^{\pm},12^{+},12^{-})$
$M_3 = 6(O,8^{\pm},8^{+},8^{-}) = (O_6,48^{\pm},48^{+},48^{-})$.
Then Fructose $= M_1 \oplus M_2 \oplus M_3 = (C_6, 36^{\pm},36^{+},36^{-}) \oplus (H_{12},0^{\pm},12^{+},12^{-}) \oplus (O_6,48^{\pm},48^{+},48^{-})$
$= (\mathcal{F}, 84^{\pm} , 96^{+} , 96^{-})$.

Example 3.3: In this example we will make a model for Omega3 which is an example of Fats
Omega3 = C20H30O2 " "
Let $M_1 = 20(C,6^{\pm},6^{+},6^{-}) = (C_{120}, 120^{\pm},120^{+},120^{-})$, $M_2 = 30(H,0^{\pm},1^{+},1^{-}) = (H_{30},0^{\pm},30^{+},30^{-})$
$M_3 = 2(O,8^{\pm},8^{+},8^{-}) = (O_2,16^{\pm},16^{+},16^{-})$.
Then $\mathcal{O} = M_1 \oplus M_2 \oplus M_3 = (C_{120}, 120^{\pm},120^{+},120^{-}) \oplus (H_{30},0^{\pm},30^{+},30^{-}) \oplus (O_2,16^{\pm},16^{+},16^{-})$
$= (\mathcal{O}, 136^{\pm} , 166^{+} , 166^{-})$.

Example 3.4: In this example, we will make a model for Gluten as an example of Protein
Gluten = C5H10N2O3 " "
Let $M_1 = 5(C,6^{\pm},6^{+},6^{-}) = (C_5, 30^{\pm},30^{+},30^{-})$, $M_2 = 10(H,0^{\pm},1^{+},1^{-}) = (H_{10},0^{\pm},10^{+},10^{-})$
$M_3 = 2(N,7^{\pm},7^{+},7^{-}) = (N_2,14^{\pm},14^{+},14^{-})$, $M_4 = 3(O,8^{\pm},8^{+},8^{-}) = (O_3,24^{\pm},24^{+},24^{-})$.
Then $\mathcal{S} = M_1 \oplus M_2 \oplus M_3 \oplus N_4 = (C_5, 30^{\pm},30^{+},30^{-}) \oplus (H_{10},0^{\pm},10^{+},10^{-}) \oplus (N_2,14^{\pm},14^{+},14^{-}) \oplus (O_3,24^{\pm},24^{+},24^{-}) = (\mathcal{S}, 68^{\pm} , 78^{+}, 78^{-})$.

4- Chemical (inorganic) molecules modeled by a signal soft set

In this section, we will study some basic types of inorganic molecules represented as a signal soft set: water, acids, bases, salts

Examples 4.1

1- Water: $2 (H,0^{\pm},1^{+},1^{-}) \oplus (O,8^{\pm},8^{+},8^{-}) = (H_2,0^{\pm},2^{+},2^{-}) \oplus (O,8^{\pm},8^{+},8^{-}) = (H_2O ,8^{\pm},10^{+},10^{-})$.
2- Acids: "Carbonic Acids" $= (H_2,0^{\pm},2^{+},2^{-}) \oplus (C,6^{\pm},6^{+},6^{-}) \oplus (O_3,24^{\pm},24^{+},24^{-})$ $(H2CO3,30^{\pm},32^{+},32^{-})$.
3- Salts: "Ammonium" $= (N,7^{\pm},7^{+},7^{-}) \oplus (H4,0^{\pm},4^{+},4^{-}) = (NH4,7^{\pm},11^{+},11^{-})$.
4- Bases: "Calcium Hydroxide" $= (Ca,20^{\pm},20^{+},20^{-}) \oplus (O_2,16^{\pm},16^{+},16^{-}) \oplus (H_2,0^{\pm},2^{+},2^{-}) = (Ca(OH)_2 ,36^{\pm}, 38^{+}, 38^{-})$

5- Anti-molecules modeled by a signal soft set

In this section, we will introduce the anti-molecules as the anti-signal soft set model we will use the symbol $\acute{M}$ for the anti-signal soft set to study molecules with anti- molecules, show mathematically that the summation of molecules and its anti- molecules will give pure energy.

Model 5.1: Let $N = (N , \eta^{\delta}, \rho^{\delta}, \varepsilon^{\delta})$ be a signal soft set model of some atom.Then, the anti-signal soft set model of N is defined by $\acute{N} = (\overline{N} , \overline{\eta}^{\lambda} , \overline{\rho}^{\lambda}, \overline{\varepsilon}^{\lambda})$, where $\lambda = - \delta$
(Which represent the anti-atom in general).

Model 5. 2: Let $\breve{M}_1 = (\bar{N}_1, \bar{\eta}_1^{\delta 1}, \bar{\rho}_1^{\delta 2}, \bar{\varepsilon}_1^{\delta 3})$, $\breve{M}_2 = (\bar{N}_2, \bar{\eta}_2^{\sigma 1}, \bar{\rho}_2^{\sigma 2}, \bar{\varepsilon}_2^{\sigma 3})$,…, $\breve{M}_n = (\bar{N}_n, \bar{\eta}_n^{\alpha 1}, \bar{\rho}_n^{\alpha 2}, \bar{\varepsilon}_n^{\alpha 3})$ are anti-signal soft sets (anti-atoms) . Their summation is a (anti – molecular $\acute{M}$) defined by:
$\breve{M}_1 \oplus \breve{M}_2 \oplus \ldots \oplus \breve{M}_n = (\bar{N}_1, \bar{\eta}_1^{\delta 1}, \bar{\rho}_1^{\delta 2}, \bar{\varepsilon}_1^{\delta 3}) \oplus (\bar{N}_2, \bar{\eta}_2^{\sigma 1}, \bar{\rho}_2^{\sigma 2}, \bar{\varepsilon}_2^{\sigma 3}) \oplus \ldots \oplus (\bar{N}_n, \bar{\eta}_n^{\alpha 1}, \bar{\rho}_n^{\alpha 2}, \bar{\varepsilon}_n^{\alpha 3}) = \acute{M}$
$= (\bar{N}, \bar{\eta}_1^{\delta 1} + \bar{\eta}_2^{\sigma 1} + \bar{\eta}_n^{\alpha 1}, \bar{\rho}_1^{\delta 2} + \bar{\rho}_2^{\sigma 2} + \bar{\rho}_n^{\alpha 2}, \bar{\varepsilon}_1^{\delta 3} + \bar{\varepsilon}_2^{\sigma 3} + \bar{\varepsilon}_n^{\alpha 3})$.

Model 5. 3: Let $\breve{M}_1 = (\bar{N}_1, \bar{\eta}_1^{\delta 1}, \bar{\rho}_1^{\delta 2}, \bar{\varepsilon}_1^{\delta 3})$, $\breve{M}_2 = (\bar{N}_2, \bar{\eta}_2^{\sigma 1}, \bar{\rho}_2^{\sigma 2}, \bar{\varepsilon}_2^{\sigma 3})$, ….. $\breve{M}_n = (\bar{N}_n, \bar{\eta}_n^{\alpha 1}, \bar{\rho}_n^{\alpha 2}, \bar{\varepsilon}_n^{\alpha 3})$ are anti-signal soft sets (it could be anti-atoms , anti – molecules or both) . Their summation is a (anti – molecular $\acute{M}$) defined by :
$\breve{M}_1 \oplus \breve{M}_2 \oplus \ldots \oplus \breve{M}_n = (\bar{N}_1, \bar{\eta}_1^{\delta 1}, \bar{\rho}_1^{\delta 2}, \bar{\varepsilon}_1^{\delta 3}) \oplus (\bar{N}_2, \bar{\eta}_2^{\sigma 1}, \bar{\rho}_2^{\sigma 2}, \bar{\varepsilon}_2^{\sigma 3}) \oplus \ldots \oplus (\bar{N}_n, \bar{\eta}_n^{\alpha 1}, \bar{\rho}_n^{\alpha 2}, \bar{\varepsilon}_n^{\alpha 3})$
$= \acute{M} = (\bar{N}, \bar{\eta}_1^{\delta 1} + \bar{\eta}_2^{\sigma 1} + \bar{\eta}_n^{\alpha 1}, \bar{\rho}_1^{\delta 2} + \bar{\rho}_2^{\sigma 2} + \bar{\rho}_n^{\alpha 2}, \bar{\varepsilon}_1^{\delta 3} + \bar{\varepsilon}_2^{\sigma 3} + \bar{\varepsilon}_n^{\alpha 3})$.

Example 5.4: In this example we will make a model for anti - Fructose " $\bar{\mathcal{F}}$ " where Fructose = ($\mathcal{F}$, $84^{\pm}$, 96^{+} , 96^{-}), since
$M_1 = (C_6, 36^{\pm}, 36^{+}, 36^{-})$ then $\breve{M}_1 = (\bar{C}_6, 36^{\mp}, 36^{-}, 36^{+})$
$M_2 = (H_{12}, 0^{\pm}, 12^{+}, 12^{-})$ then $\breve{M}_2 = (\bar{H}_{12}, 0^{\mp}, 12^{-}, 12^{+})$
$M_3 = (O_6, 48^{\pm}, 48^{+}, 48^{-})$ then $\breve{M}_3 = (\bar{O}_6, 48^{\mp}, 48^{-}, 48^{+})$
Then, anti - Fructose = $\breve{M}_1 \oplus \breve{M}_2 \oplus \breve{M}_3 = (\bar{C}_6, 36^{\mp}, 36^{-}, 36^{+}) \oplus (\bar{H}_{12}, 0^{\mp}, 12^{-}, 12^{+}) \oplus (\bar{O}_6, 48^{\mp}, 48^{-}, 48^{+}) = (\bar{\mathcal{F}}, 84^{\mp}, 96^{-}, 96^{+})$.

Example 5.5: Let $\xi = (\emptyset, 0^{\pm}, 0^{+}, 0^{-})$, $\bar{\xi} = (\bar{\emptyset}, 0^{\mp}, 0^{-}, 0^{+})$ be an energy and anti-energy signal soft sets . Then, the summation is defined as follow :
$\xi \oplus \bar{\xi} = (\emptyset, 0^{\pm}, 0^{+}, 0^{-}) \oplus (\bar{\emptyset}, 0^{\mp}, 0^{-}, 0^{+}) = (\emptyset + \bar{\emptyset}, 0^{\pm} + 0^{\mp}, 0^{+} + 0^{-}, 0^{-} + 0^{+})$
$= (\varnothing, \phi^{\varphi}, \phi^{\varphi}, \phi^{\varphi}) = PE$, Similarly $\bar{\xi} \oplus \xi = PE$.

Remark 5.6: Any molecules with anti- molecules equals pure energy PE.

Example 5.7: For Fructose = ($\mathcal{F}$, $84^{\pm}$, 96^{+} , 96^{-}) and anti - Fructose $\breve{F} = (\bar{\mathcal{F}}, 84^{\mp}, 96^{-}, 96^{+})$
($\mathcal{F}$, $84^{\pm}$, 96^{+} , 96^{-}) $\oplus$ ($\bar{\mathcal{F}}$, $84^{\mp}$, 96^{-} , 96^{+}) = = ($\varnothing$, ϕ^{φ}, ϕ^{φ} , ϕ^{φ}) = PE

6- Signal soft topological space (for molecules)

In this section, we will use molecular to define signal soft topologies, for many cases, in reality, we deal with finite structures so we will need to define signal soft topology for molecules that use finite signal soft sets for atoms.

Definition 6.1: Let $M_1 = (M_1, \eta_1, \rho_1, \varepsilon_1)$, $M_2 = (M_2, \eta_2, \rho_2, \varepsilon_2)$ be two molecules (or atoms or both). Then, the union of two molecules $M_1 \Cup M_2 = M_3 = (M_3, \eta_3, \rho_3, \varepsilon_3)$,

$$\eta_3 = \begin{cases} \text{if } \eta_1 \neq \eta_2 \Rightarrow [\eta_3 = max\{\eta_1, \eta_2\}] \\ \text{if } \eta_1 = \eta_2 \Rightarrow [\eta_3 = \eta_1 \vee \eta_2] \end{cases}$$

and similarly for ρ_3 , ε_3 .

Definition 6.2: Let $M_1 = (M_1, \eta_1, \rho_1, \varepsilon_1)$, $M_2 = (M_2, \eta_2, \rho_2, \varepsilon_2)$ be two molecules (or atoms or both). Then, the intersection of two molecules $M_1 \Cap M_2 = M_3 = (M_3, \eta_3, \rho_3, \varepsilon_3)$,

$$\eta_3 = \begin{cases} \text{if } \eta_1 \neq \eta_2 \Rightarrow [\eta_3 = min\{\eta_1, \eta_2\}] \\ \text{if } \eta_1 = \eta_2 \Rightarrow [\eta_3 = \eta_1 \vee \eta_2] \end{cases}$$

and similarly for ρ_3 , ε_3 .

Definition 6.3; Let X be a non-empty set , E be a finite set of parameters (X , E), T be a collection of finite signal soft sets generated by non-null finite signal soft set (molecular - M) if T satisfies the following axioms :
(1) Φ and M are in T.
(2) ⋓ of any members of signal soft sets in T belongs to T.
(3) ⋒ of any two signal soft sets in T belong to T.
Then, T is called signal soft topology on M (simply T is *S* M - topology), the triple (M ,T , E) is called signal soft topological space on molecules M (simply S_M - space), the signal soft sets of T are called S_M - open sets and their complements are called S_M - closed sets.

Examples 6.4:
1- Let $\Phi = (\emptyset , 0^{\pm} , 0^{+} , 0^{-})$, M = $(NH4,7^{\pm},11^{+},11^{-})$.
Then, T = {Φ , M } is the S_M - Indiscrete topology.
2- Let M = (H4 , $0^{\pm}$, 4^{+} , 4^{-}) , Φ = (∅ , $0^{\pm}$, 0^{+} , 0^{-})
U = $(NH4,7^{\pm},11^{+},11^{-})$.
Then, T = {Φ ,U , M } is S_U - topology since
M ⋒ Φ = (H4 , $0^{\pm}$, 4^{+} , 4^{-}) ⋒ (∅ , $0^{\pm}$, 0^{+} , 0^{-}) = Φ
M ⋒U = (H4 , $0^{\pm}$, 4^{+} , 4^{-}) ⋒ $(NH4,7^{\pm},11^{+},11^{-})$ = M
U ⋒ Φ = $(NH4,7^{\pm},11^{+},11^{-})$ ⋒ (∅ , $0^{\pm}$, 0^{+} , 0^{-}) = Φ
M ⋓ Φ = (H4 , $0^{\pm}$, 4^{+} , 4^{-}) ⋓ (∅ , $0^{\pm}$, 0^{+} , 0^{-}) = M
M ⋓ U = (H4 , $0^{\pm}$, 4^{+} , 4^{-}) ⋓ $(NH4,7^{\pm},11^{+},11^{-})$ = U
U ⋓ Φ = $(NH4,7^{\pm},11^{+},11^{-})$ ⋓ (∅ , $0^{\pm}$, 0^{+} , 0^{-}) = U
and (U ,T , E) is S_U - space .

Definition 6.5: Let (M , T , E) be S_M - space, x ∈ M.Then, M is said to be S_M - neighborhood of x if there exist an S_M - open set N (atom) such that x ∈N ⊆ M, or there exist an S_M - open set M_1 (molecular) such that x ∈ M_1 ⊆ M.

Remark 6.6: Every S_M - open set is S_M - neighborhood, the converse is not true in general.

Example 6.7: Let M_1 = (H_2,$0^{\pm}$,2^{+},2^{-}), M_2 = (H_2CO_3,$30^{\pm}$,32^{+},32^{-}), M_2 = (H_2,$0^{\pm}$,2^{+},2^{-}) ⊕ (C,$6^{\pm}$,6^{+},6^{-}) ⊕ (O_3,$24^{\pm}$,24^{+},24^{-})
Φ = (∅ , $0^{\pm}$, 0^{+} , 0^{-}), T = { Φ , M_1 , M_2 } is S_{M2} - topology
M_2 is S_{M2} - open since M_2 ∈ T, also M_2 is S_{M2} - neighborhood of x_1= (H, $0^{\pm}$) , since $x_1 \in M_1 \subseteq M_2$
and M_3 = $Ca(OH)_2$ = (Ca,$20^{\pm}$,20^{+},20^{-}) ⊕ (O_2,$16^{\pm}$,16^{+},16^{-}) ⊕ (H_2,$0^{\pm}$,2^{+},2^{-})
M_3 is S_{M2} - neighborhood of x_1 = (H, $0^{\pm}$) , since $x_1 \in M_1 \subseteq M_3$ but M_3 is not S_{M2} - open since $M_3 \notin$ T.

Example 6.8: Let M = ($\mathcal{F}$, $84^{\pm}$, 96^{+} , 96^{-}) , Φ = (∅ , $0^{\pm}$, 0^{+} , 0^{-}) .
Then, T = {Φ , M} is S_M - topology which is indiscrete signal soft topology
M is S_M - open since $M \in$ T
also M is S_M - neighborhood of x_1= ($\mathcal{F}$, $84^{\pm}$) , x_2= ($\mathcal{F}$, 96^{+}) , x_3= ($\mathcal{F}$, 96^{-})
since $x_1 \in M \subseteq M$ .Then, M *is* S_M - neighborhood of x_1 similarly for x_2, x_3.

Example 6.9: Let M_1 = (C_4, $24^{\pm}$,24^{+},24^{-}) , M_2 = (H_5,$0^{\pm}$,5^{+},5^{-}) , M_3 = (N_3,$21^{\pm}$,21^{+},21^{-})
N_4 = Oxygen = (O,$8^{\pm}$,8^{+},8^{-}) .
Then, the Cytosine = $M_1 \oplus M_2 \oplus M_3 \oplus N_4$ = ($\mathcal{C}$, $53^{\pm}$, 58^{+} , 58^{-})
Φ = (∅ , $0^{\pm}$, 0^{+} , 0^{-}) , T = { Φ , M_1 , $\mathcal{C}$ } is $S_{\mathcal{C}}$ - topology .
M_1 is $S_{\mathcal{C}}$ - open since $M_1 \in$ T , M_1 is $S_{\mathcal{C}}$ - neighborhood of x_1= (C_4, $24^{\pm}$) , since $x_1 \in M_1 \subseteq \mathcal{C}$

M_1 is not $S_{\mathcal{C}}$ - neighborhood of $x_2 = (H_5, 0^{\pm})$, $\mathcal{C}$ is $S_{\mathcal{C}}$ - neighborhood of $x_2 = (H_5, 0^{\pm})$.

Example 6.10: It is possible to generate a signal soft topology for anti - molecular as seen in this example.
Let anti - Fructose = $\acute{\Gamma} = \breve{M}_1 \oplus \breve{M}_2 \oplus \breve{M}_3$
$= (\bar{C}_6, 36^{\mp}, 36^{-}, 36^{+}) \oplus (\bar{H}_{12}, 0^{\mp}, 12^{-}, 12^{+}) \oplus (\bar{O}_6, 48^{\mp}, 48^{-}, 48^{+}) = (\bar{\mathcal{F}}, 84^{\mp}, 96^{-}, 96^{+})$.
$\Phi = (\emptyset , 0^{\pm} , 0^{+} , 0^{-})$, $T = \{ \Phi , \breve{M}_1, \acute{\Gamma} \}$ is $S_{\acute{\Gamma}}$ - topology .
$\acute{\Gamma}$ is $S_{\acute{\Gamma}}$ - open, also is $S_{\acute{\Gamma}}$ - neighborhood of $x_1 = (\bar{O}_6, 48^{\mp})$, since $x_1 \in \acute{\Gamma} \subseteq \acute{\Gamma}$.

Conclusion

In this paper we show that molecular can be represented as a signal soft set, from a signal soft set for molecular we can generate a signal soft topology for molecular, we introduce the anti – molecular in a new mathematical way (we show that the anti-molecular is a complement of a signal soft set of the molecular) and show that the molecular with anti - molecular will generate a pure energy

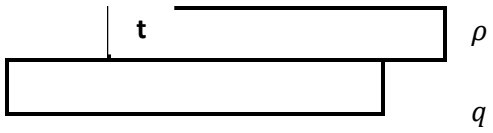
Abstract. The aim of this work is, to study the resolution of a two-row weyl module in the case of skew partitions(9,7)/(s,0), when s=1,2, by using the technique of letter place algebra, place map(polarization) and contraction homotopy. The skew partitions case is one of the uncles of this study.

1. Introduction

Let $\mathcal{F}$ be a free R-module over commutative ring $\mathcal{R}$ with identity 1 and $Ð_s\mathcal{F}$ is divided power algebra of degrees s. Keep in mind the theory associated to the resolution of two-rowed weyl module $K_{\lambda/\mu}\mathcal{F}$, that been previously described in [1], as follows:

λ/μ =



And $d'_{\lambda/\mu}: Ð_{\lambda/\mu}\mathcal{F} \longrightarrow \Lambda^{\tilde{\lambda}/\tilde{\mu}}\mathcal{F}$ it is the Weyl map will be called "Weyl module" Where $K_{\lambda/\mu}\mathcal{F} = Im(d'_{\lambda/\mu})$. [2]

So we have:

$$0 \longrightarrow \sum Ð_{p+k} \otimes Ð_{q-k} \xrightarrow{\square} Ð_p \otimes Ð_q \xrightarrow{d'_{\lambda/\mu}} K_{\lambda/\mu} \longrightarrow \quad (1)$$

Using by letter place, the maps can be written as below:

$$\binom{w}{w'}\Big|\begin{matrix}1^{(p+k)}\\2^{(q-k)}\end{matrix}\xrightarrow{\partial_{21}^{(k)}}\binom{w}{w'}\Big|\begin{matrix}1^{(p)}2^{(k)}\\2^{(q-k)}\end{matrix}\Big)$$
$$\rightarrow\sum w\begin{pmatrix}w_1\\w'^{w_2}\end{pmatrix}\Big|\begin{matrix}(t+1)'(t+2)'\dots\dots(p+t)'\\1'2'3'\dots q'\end{matrix}\Big) \qquad (2)$$

Where $w\otimes w'\in Ð_{p+k}\otimes Ð_{q-k}$, $\square=\sum_{k=t+1}^{q}\partial_{21}^{(k)}$ is the box map,

And $d'_{\lambda/\mu}=\partial_{q'2}\dots\partial_{1'2}\partial_{(p+t)'1}\dots\partial_{q(t+1)'1}$, is the composition of place polarization, from positive places $\{1,2\}$ to negative places $\{1',2',\dots,(p+t)'\}$.

Then, as shown in [2], $\square$ is deliver a component $x\otimes y$ of $Ð_{p+k}\otimes Ð_{q-k}$ to $\sum x_p\otimes x'_k y$, where $\sum x_p\otimes x'_k$ is the element of the diagonal of x in $Ð_p\otimes Ð_q$.

"Let $(\mathcal{Z}_{21})$ be the free generator of divided power algebra $Ð(\mathcal{Z}_{21})$ in one generator, the divided power element $\mathcal{Z}_{21}^{(k)}$ of degree k of the free generator $\mathcal{Z}_{21}$ acts on $Ð_{p+k}\otimes Ð_{q-k}$ by place polarization of degree k from place (1) to place (2)" [3].
"The ''graded'' algebra with identity. $A=Ð(\mathcal{Z}_{21})$ acts on the graded module $\mathcal{M}=Ð_{p+k}\otimes Ð_{q-k}=\sum\mathcal{M}_{q-k}$.[3]"
"Hence, $\mathcal{M}$ is a graded left A-module, where for $w=\mathcal{Z}_{21}^{(k)}\in A$ and $\mathbb{v}\in Ð_{\beta1}\otimes Ð_{\beta2}$, So we have:"

$$w(\mathbb{v})=\mathcal{Z}_{21}^{(k)}(\mathbb{v})=\partial_{21}^{(k)}(\mathbb{v})$$

If we take t^+graded strand of degree q.
$\mathcal{M}_\bullet: 0\rightarrow\mathcal{M}_{q-t}\xrightarrow{\partial_s}\dots\rightarrow\mathcal{M}_e\xrightarrow{\partial_s}\mathcal{M}_1\xrightarrow{\partial_s}\mathcal{M}_0$,
Of the normalized Bar complex, Bar $(\mathcal{M},A,S;\bullet)$,where $S=\{x\}$. Some important standard concepts which are needed in our work are illustrated.
The maps $\{S_i\}$ are defined as follows: [2]
$S_0: Ð_p\otimes Ð_q\rightarrow\sum_{k>0}\mathcal{Z}^{(t+k)}x\,Ð_{p+t+k}\otimes Ð_{q-t-k}$

$$\binom{w}{w'}\Big|\begin{matrix}1^{(p)}\ 2^{(\mathrm{K})}\\2^{(q-\mathrm{K})}\end{matrix}\Big)\longrightarrow\begin{cases}\mathcal{Z}_{21}^{(\mathrm{K})}x\binom{w}{w'}\Big|\begin{matrix}1^{(p+\mathrm{K})}\\2^{(q-\mathrm{K})}\end{matrix}\Big) & ;if\ \mathrm{K}\leq t\\0 & ;if\ \mathrm{K}>t\end{cases}$$

And for the higher dimensionses as:

$$S_{\iota-1}:\sum_{\mathrm{K}\iota>0}\mathcal{Z}_{21}^{(t+\mathrm{K}_1)}x\,\mathcal{Z}_{21}^{(\mathrm{K}_2)}x\dots.\mathcal{Z}_{21}^{(\mathrm{K}_{\iota-1})}x\,Ð_{p+t+|\mathrm{K}|}\otimes Ð_{q-t-|\mathrm{K}|}\ \rightarrow$$
$$\mathcal{Z}_{21}^{(t+\mathrm{K}_1)}x\mathcal{Z}_{21}^{(\mathrm{K}_2)}x\dots.\mathcal{Z}_{21}^{(\mathrm{K}_{\iota-1})}x\,\mathcal{Z}_{21}^{(\mathrm{K}_\iota)}xÐ_{p+t+|\mathrm{K}|}\otimes Ð_{q-t-|\mathrm{K}|}$$

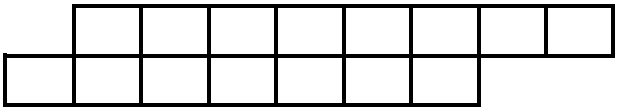
$$\mathcal{Z}_{21}^{(t+\mathrm{K}_1)}x\mathcal{Z}_{21}^{(\mathrm{K}_2)}x\dots.\mathcal{Z}_{21}^{(\mathrm{K}_{\iota-1})}x\begin{pmatrix}w\\w'\end{pmatrix}\Big|\begin{matrix}1^{(p+t+|\mathrm{K}|)}\ 2^{(\mathrm{v})}\\2(q-t-|\mathrm{K})\end{matrix}\Big)\longrightarrow$$
$$\begin{cases}\mathcal{Z}_{21}^{(t+\mathrm{K}_1)}x\mathcal{Z}_{21}^{(\mathrm{K}_2)}x\dots.\mathcal{Z}_{21}^{(\mathrm{K}_{\iota-1})}x\mathcal{Z}_{21}^{(\mathrm{v})}x\binom{w}{w'}\Big|\begin{matrix}1^{(p+t+|\mathrm{K}|)}\ 2^{(\mathrm{v})}\\2(q-t-|\mathrm{K})\end{matrix}\Big) & ;if\ \mathrm{v}>0\\0 & ;if\ \mathrm{v}=0\end{cases}$$

Whereas the modules of the resolution were written as:-
$(\mathcal{M}_i)$ for $(i=0,1,\dots\dots.q-t)$,with $\mathcal{M}_0=Ð_p\otimes Ð_q$, and
$\mathcal{M}_i=\mathcal{Z}_{21}^{(t+\mathrm{K}_1)}x\mathcal{Z}_{21}^{(\mathrm{K}_2)}x\dots.\mathcal{Z}_{21}^{(\mathrm{K}_i)}xÐ_{p+t+|\mathrm{K}|}\otimes Ð_{q-t-|\mathrm{K}|}\,;for\ i\geq1$ [2].

The resolution of weyl module in the case of two-rowed skew- shape $(p^+,t,q)/(t,0)$. [4];Whereas another study [5] exhibited the terms and the exactness of the weyl resolution in the cases of partition (9,7).In this work , we locate the terms and the exactness of the weyl resolution in the case of skew-shape $(9,7)/(t,0)$, $t=1,2$

2. The results of the case (9,7)/(1,0)

This section ,we find the term Weyl module resolution in the cases of a skew partition (9,7)/(1,0) and give the proof of its exactness



The expression of the characteristic-free weyl resolution are:

$$\mathcal{M}_0 = Đ_8 \otimes Đ_7$$

$$\mathcal{M}_1 = Z_{21}^{(2)}\chi\ Đ_{10}\otimes Đ_5 \oplus Z_{21}^{(3)}\chi\ Đ_{11}\otimes Đ_4 \oplus Z_{21}^{(4)}\chi\ Đ_{12}\otimes Đ_3 \oplus Z_{21}^{(5)}\chi\ Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(6)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(7)}\chi\ Đ_{15}\otimes Đ_0$$

$$\mathcal{M}_2 = Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi\ Đ_{11}\otimes Đ_4 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi\ Đ_{12}\otimes Đ_3 \oplus Z_{21}^{(2)}\chi Z_{21}^{(2)}\chi\ Đ_{12}\otimes Đ_3 \oplus Z_{21}^{(4)}\chi Z_{21}^{(1)}\chi\ Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(3)}\chi Z_{21}^{(2)}\chi\ Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(2)}\chi Z_{21}^{(3)}\chi\ Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(5)}\chi Z_{21}^{(1)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(4)}\chi Z_{21}^{(2)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(2)}\chi Z_{21}^{(4)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(3)}\chi Z_{21}^{(3)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(6)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(5)}\chi Z_{21}^{(2)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(5)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(4)}\chi Z_{21}^{(3)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(3)}\chi Z_{21}^{(4)}\chi\ Đ_{15}\otimes Đ_0$$

$$\mathcal{M}_3 = Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Đ_{12}\otimes Đ_3 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(2)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi\ Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(4)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(3)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(5)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(4)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(4)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(4)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(4)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(3)}\chi Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(3)}\chi\ Đ_{15}\otimes Đ_0$$

$$\mathcal{M}_4 = Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{13}\otimes Đ_2 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(2)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(4)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(3)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(3)}\chi\ Đ_{15}\otimes Đ_0$$

$$\mathcal{M}_5 = Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{14}\otimes Đ_1 \oplus Z_{21}^{(3)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi\ Đ_{15}\otimes Đ_0 \oplus Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(2)}\chi\ Đ_{15}\otimes Đ_0$$

$$\mathcal{M}_6 = Z_{21}^{(2)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\, Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi Z_{21}^{(1)}\chi\ Ð_{15}\otimes Ð_0$$

2.1 Case 1

The constructions of a contracting homotopies $\{S_i\}$, where i=1, 2, …… , 5

$S_0 = \mathcal{M}_0 \to \mathcal{M}_1$

$$S_0\left(\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(8)}2^{(K)} \\ 2^{(7-K)} \end{matrix}\right) = \begin{cases} Z_{21}^{(K)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(8+K)} \\ 2^{(7-K)} \end{matrix} & ;\ if\ K = 2,3,4,\ldots.7 \\ 0 & ;if\ K \le 2 \end{cases}$$

and

$S_1 = \mathcal{M}_1 \to \mathcal{M}_2$

$$S_1\left(Z_{21}^{(K+1)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+K)}2^{(v)} \\ 2^{(6-K-v)} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(K+1)}\chi Z_{21}^{(v)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+K+v)} \\ 2^{(6-K-v)} \end{matrix} & ;\ if\ v = 1,2,3,4,5 \\ 0 & ;if\ v = 0 \end{cases}$$

and

$S_2 = \mathcal{M}_2 \to \mathcal{M}_3$

$$S_2\left(Z_{21}^{(K_1+1)}\chi Z_{21}^{(K_2)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+|K|)}2^{(v)} \\ 2^{(6-|K|-v)} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(K_1+1)}\chi Z_{21}^{(K_2)}\chi Z_{21}^{(v)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+|K|+v)} \\ 2^{(6-|K|-v)} \end{matrix} & ;\ if\ v = 1,2,3,4 \\ 0 & ;\ if\ v = 0 \end{cases} ;\ where|K| = K_1 + K_2$$

and

$S_3 = \mathcal{M}_3 \to \mathcal{M}_4$

$$S_3\left(Z_{21}^{(K_1+1)}\chi Z_{21}^{(K_2)}\chi Z_{21}^{(K_3)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+|K|)}2^{(v)} \\ 2^{(6-|K|-v)} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(K_1+1)}\chi Z_{21}^{(K_2)}\chi Z_{21}^{(K_3)}\chi Z_{21}^{(v)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+|K|+v)} \\ 2^{(6-|K|-v)} \end{matrix} & ;\ if\ v = 1,2,3 \\ 0 & ;if\ v = 0 \end{cases} ;where|K| = K_1 + K_2 + K_3$$

and

$S_4 = \mathcal{M}_4 \to \mathcal{M}_5$

$$S_4\left(Z_{21}^{(K_1+1)}\chi Z_{21}^{(K_2)}\chi Z_{21}^{(K_3)}\chi Z_{21}^{(K_4)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+|K|)}2^{(v)} \\ 2^{(6-|K|-v)} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(K_1+1)}\chi Z_{21}^{(K_2)}\chi Z_{21}^{(K_3)}\chi Z_{21}^{(K_4)}\chi Z_{21}^{(v)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+|K|+v)} \\ 2^{(6-|K|-v)} \end{matrix} & ;\ if\ v = 1,2 \\ 0 & ;if\ v = 0 \end{cases} ;where|K| = K_1 + K_2 + K_3 + K_4$$

and

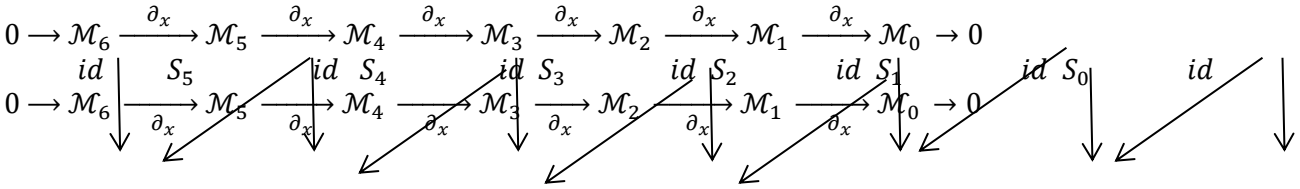
$S_5 = \mathcal{M}_5 \to \mathcal{M}_6$

$$S_5\left(Z_{21}^{(K_1+1)}\chi Z_{21}^{(K_2)}\chi Z_{21}^{(K_3)}\chi Z_{21}^{(K_4)}\chi Z_{21}^{(K_5)}\chi\begin{pmatrix} W \\ W' \end{pmatrix}\middle| \begin{matrix} 1^{(9+|K|)}2^{(v)} \\ 2^{(6-|K|-v)} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi Z_{21}^{(\mathrm{K}_3)}\chi Z_{21}^{(\mathrm{K}_4)}\chi Z_{21}^{(\mathrm{K}_5)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix}; if\ \mathrm{v}=1 \\ 0 \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad ;\ if\ \ \mathrm{v}=0 \end{cases}; where|\mathrm{K}|$$

$$= \mathrm{K}_1 + \mathrm{K}_2 + \mathrm{K}_3 + \mathrm{K}_4 + \mathrm{K}_5$$

So we have the following diagram:-



2.2 Case 2

Now, we have

$$S_0\partial_x\left(Z_{21}^{(\mathrm{K}+1)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K})}2^{(\mathrm{v})} \\ 2^{(6-\mathrm{K})} \end{matrix}\end{pmatrix}\right) = S_0\partial_{21}^{(\mathrm{K}+1)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K})}2^{(\mathrm{v})} \\ 2^{(6-\mathrm{K})} \end{matrix}\end{pmatrix}$$

$$= \binom{\mathrm{K}+1+\mathrm{v}}{\mathrm{v}} Z_{21}^{(\mathrm{K}+1+\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K}+\mathrm{v})} \\ 2^{(6-\mathrm{K}-\mathrm{v})} \end{matrix}\end{pmatrix}$$

and

$$\partial_x S_1\left(Z_{21}^{(\mathrm{K}+1)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K})}2^{(\mathrm{v})} \\ 2^{(6-\mathrm{K})} \end{matrix}\end{pmatrix}\right) = \partial_x\left(Z_{21}^{(\mathrm{K}+1)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K}+\mathrm{v})} \\ 2^{(6-\mathrm{K}-\mathrm{v})} \end{matrix}\end{pmatrix}\right)$$

$$= -\binom{\mathrm{K}+1+\mathrm{v}}{\mathrm{v}} Z_{21}^{(\mathrm{K}+1+\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K}+\mathrm{v})} \\ 2^{(6-\mathrm{K}-\mathrm{v})} \end{matrix}\end{pmatrix} + Z_{21}^{(\mathrm{K}+1)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K})}2^{(\mathrm{v})} \\ 2^{(6-\mathrm{K})} \end{matrix}\end{pmatrix}$$

It is clear that $S_0\partial_x + \partial_x S_1 = id_{\mathcal{M}_1}$.

$$S_1\partial_x\left(Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|)}2^{(\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix}\right)$$

$$= S_1\left(-\binom{|\mathrm{K}|+1}{\mathrm{K}_2} Z_{21}^{(|\mathrm{K}|+1)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|)}2^{(\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix} + Z_{21}^{(\mathrm{K}_1+1)}\chi\partial_{21}^{(\mathrm{K}_2)}\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|)}2^{(\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix}\right)$$

$$= -\binom{|\mathrm{K}|+1}{\mathrm{K}_2} Z_{21}^{(|\mathrm{K}|+1)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix} + \binom{\mathrm{K}_2+\mathrm{v}}{\mathrm{v}} Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2+\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix}$$

and

$$\partial_x\, S_2\left(Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|)}2^{(\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix}\right) = \partial_x\left(Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix}\right)$$

$$= \binom{|\mathrm{K}|+1}{\mathrm{K}_2} Z_{21}^{(|\mathrm{K}|+1)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix} - \binom{\mathrm{K}_2+\mathrm{v}}{\mathrm{v}} Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2+\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(6-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix}$$

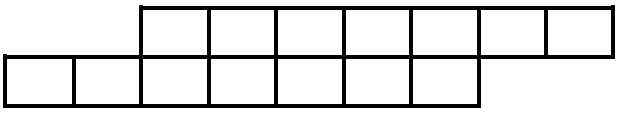
Cearly, $S_4\partial_x + \partial_x S_5 = id_{\mathcal{M}_5}$.

Form the above, we get that$\{S_0, S_1, S_2, S_3, S_4, S_5\}$ be contracting homotopy, [6] which means that our complex is exacted.

3. The results of the case (9,7)/(2,0)

In this section, we find the terms of Weyl module resolution in the case of a skew partition (9,7)/(1,0) and give the proof of its exactness



The terms of the characteristic-$f$ree resolution are:

$\mathcal{M}_0 = Đ_7 \otimes Đ_7$

$\mathcal{M}_1 = Z_{21}^{(3)}\chi\, Đ_{10}\otimes Đ_4 \oplus Z_{21}^{(4)}\chi\, Đ_{11}\otimes Đ_3 \oplus Z_{21}^{(5)}\chi\, Đ_{12}\otimes Đ_2 \oplus Z_{21}^{(6)}\chi\, Đ_{13}\otimes Đ_1 \oplus Z_{21}^{(7)}\chi\, Đ_{14}\otimes Đ_0$

3.1 Case 1

The constructions of a contracting homotopies $\{S_i\}$,where i=1, 2, ..., 4

$S_0 = \mathcal{M}_0 \to \mathcal{M}_1$

$$S_0\left(\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(7)}2^{(\mathrm{K})} \\ 2^{(7-\mathrm{K})} \end{matrix}\right) = \begin{cases} Z_{21}^{(\mathrm{K})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(7+\mathrm{K})} \\ 2^{(7-\mathrm{K})} \end{matrix}\end{pmatrix} & ;\ if\ \mathrm{K} = 3,4,\ldots.7 \\ 0 & ;if\ \ \mathrm{K} \le 2 \end{cases}$$

And

$$S_1 = \mathcal{M}_1 \to \mathcal{M}_2$$

$$S_1\left(Z_{21}^{(\mathrm{K}+1)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K})}2^{(\mathrm{v})} \\ 2^{(5-\mathrm{K}-\mathrm{v})} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(\mathrm{K}+1)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+\mathrm{K}+\mathrm{v})} \\ 2^{(5-\mathrm{K}-\mathrm{v})} \end{matrix}\end{pmatrix} & ;\ if\ \mathrm{v} = 1,2,3,4 \\ 0 & ;if\ \ \mathrm{v} = 0 \end{cases}$$

And

$$S_2 = \mathcal{M}_2 \to \mathcal{M}_3$$

$$S_2\left(Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|)}2^{(\mathrm{v})} \\ 2^{(5-|\mathrm{K}|-\mathrm{v})} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(5-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix} & ;\ if\ \mathrm{v} = 1,2,3 \\ 0 & ;if\ \ \mathrm{v} = 0 \end{cases} \quad ;Where|\mathrm{K}| = \mathrm{K}_1 + \mathrm{K}_2$$

and

$$S_3 = \mathcal{M}_3 \to \mathcal{M}_4$$

$$S_3\left(Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi Z_{21}^{(\mathrm{K}_3)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|)}2^{(\mathrm{v})} \\ 2^{(5-|\mathrm{K}|-\mathrm{v})} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi Z_{21}^{(\mathrm{K}_3)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(5-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix} & ;\ if\ \mathrm{v} = 1,2 \\ 0 & ;if\ \ \mathrm{v} = 0 \end{cases} \quad ;Where|\mathrm{K}| = \mathrm{K}_1 + \mathrm{K}_2 + \mathrm{K}_3$$

and

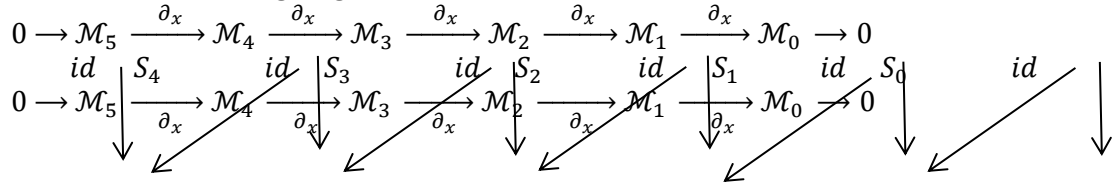
$$S_4 = \mathcal{M}_4 \to \mathcal{M}_5$$

$$S_4\left(Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi Z_{21}^{(\mathrm{K}_3)}\chi Z_{21}^{(\mathrm{K}_4)}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|)}2^{(\mathrm{v})} \\ 2^{(5-|\mathrm{K}|-\mathrm{v})} \end{matrix}\right)$$

$$= \begin{cases} Z_{21}^{(\mathrm{K}_1+1)}\chi Z_{21}^{(\mathrm{K}_2)}\chi Z_{21}^{(\mathrm{K}_3)}\chi Z_{21}^{(\mathrm{K}_4)}\chi Z_{21}^{(\mathrm{v})}\chi\begin{pmatrix} W \\ W' \end{vmatrix} \begin{matrix} 1^{(9+|\mathrm{K}|+\mathrm{v})} \\ 2^{(5-|\mathrm{K}|-\mathrm{v})} \end{matrix}\end{pmatrix} & ;\ if\ \mathrm{v} = 1 \\ 0 & ;if\ \ \mathrm{v} = 0 \end{cases} \quad ;Where|\mathrm{K}|$$

$$= \mathrm{K}_1 + \mathrm{K}_2 + \mathrm{K}_3 + \mathrm{K}_4$$

So we have the following diagram:-



3.2 Case 2

Now, we have

$$S_0\partial_x\left(Z_{21}^{(\mathrm{K}+2)}\chi\binom{W}{W'}\middle|\frac{1^{(9+\mathrm{K})}}{2^{(5-\mathrm{K})}}2^{(v)}\right)=S_0\partial_{21}^{(\mathrm{K}+2)}\chi\binom{W}{W'}\middle|\frac{1^{(9+\mathrm{K})}}{2^{(5-\mathrm{K})}}2^{(v)}\Big)$$
$$=\binom{\mathrm{K}+2+v}{v}Z_{21}^{(\mathrm{K}+2+v)}\chi\binom{W}{W'}\middle|\frac{1^{(9+\mathrm{K}+v)}}{2^{(5-\mathrm{K}-v)}}\Big)$$
and
$$\partial_x S_1\left(Z_{21}^{(\mathrm{K}+2)}\chi\binom{W}{W'}\middle|\frac{1^{(9+\mathrm{K})}}{2^{(5-\mathrm{K})}}2^{(v)}\right)\Big)=\partial_x\left(Z_{21}^{(\mathrm{K}+1)}\chi Z_{21}^{(v)}\chi\binom{W}{W'}\middle|\frac{1^{(9+\mathrm{K}+v)}}{2^{(6-\mathrm{K}-v)}}\right)\Big)$$
$$=-\binom{\mathrm{K}+2+v}{v}Z_{21}^{(\mathrm{K}+2+v)}\chi\binom{W}{W'}\middle|\frac{1^{(9+\mathrm{K}+v)}}{2^{(6-\mathrm{K}-v)}}\Big)+Z_{21}^{(\mathrm{K}+2)}\chi\binom{W}{W'}\middle|\frac{1^{(9+\mathrm{K})}}{2^{(5-\mathrm{K})}}2^{(v)}\Big)$$
Clearly, $S_0\partial_x+\partial_x S_1=id_{\mathcal{M}_1}$.
$$S_1\partial_x\left(Z_{21}^{(\mathrm{K}_1+2)}\chi Z_{21}^{(\mathrm{K}_2)}\chi\binom{W}{W'}\middle|\frac{1^{(9+|\mathrm{K}|)}}{2^{(5-|\mathrm{K}|-v)}}2^{(v)}\right)\Big)$$

$Where\ |\mathrm{K}| = \mathrm{K}_1 + \mathrm{K}_2 + \mathrm{K}_3 + \mathrm{K}_4$
Clearly, $S_3\partial_x + \partial_x S_4 = id_{\mathcal{M}_4}$.
From the above, we get that $\{S_0, S_1, S_2, S_3, S_4\}$ be contracting *h*omotopy, [6] which means that our complex *is* exact.

Inverse Equality Co-Neighborhood Domination in Graphs

Inverse Equality Co-Neighborhood Domination in Graphs

Abstract. Let $G = (V, E)$ be a simple undirected graph without isolated vertices. A proper subset $D \subset V$ is called equality co-neighborhood dominating set of G (ENDS), if every vertex in set D is adjacent to equally number of vertices in $V - D$. In this paper, the inverse equality co-neighborhood dominating set of G (IENDS) is defined. Some properties of inverse equality co-neighborhood dominating set are determined. The inverse equality co-neighborhood domination number in some special graphs and three kinds of operations in join graphs is calculated.

1. Introduction

Let $G = (V, E)$ be an undirected, simple, and finite graph of order $|V| = n$ such that V is the vertex set and E is the edge set. A subset $D \subseteq V$ is a dominating set of G, if every vertex in $V - D$ is adjacent to at least one vertex in D. The domination number γ(G) is the minimum cardinality of a dominating set in G, which has been dealt with in this work. Is defined by $N_G(v) = \{u \in V(G): uv \in E(G)\}$ for an open neighborhood of a vertex v in G and the closed neighborhood of a vertex v in G is defined by $N_G[v] = N_G(v) \cup \{v\}$. The degree of v, $\deg(v) = |\mathrm{N_G}(v)|$ is the number of vertices which are adjacent to it. The vertex of degree zero (one) is called an isolated (pendant) vertex. The complement $\overline{\mathrm{G}}$ is the graph in which two vertices are not adjacent if and only if they are adjacent in G or vice versa. The join $G_1 + G_2$ is the graph having vertex set $V(G)_1 \cup V(G_2)$ and edge set $\mathrm{E(G_1)} \cup \mathrm{E(G_2)} \cup \{ (uv: u \in \mathrm{V(G_1)}$ and $v \in \mathrm{V(G_2)}\}$. The corona $\mathrm{G_1} \odot \mathrm{G_2}$ is the graph obtained by taking one copy of $\mathrm{G_1}$ and $|G_1|$ copies of $\mathrm{G_2}$, and then joining the $\mathrm{j^{th}}$ vertex of $\mathrm{G_1}$ to every vertex in the $\mathrm{j^{th}}$ copy of $\mathrm{G_2}$. Any notation that which not found in this paper can be found in [11]. In [1] a proper subset $D \subset V$ is called equality co-neighborhood dominating set of G (ENDS) , if every vertex in set D is adjacent to equally number of vertices in $V - D$. Domination in graphs are very important for solve many of problems of real-life and it is a vital topic that attracts most researchers especially in recent years. So many new definitions appeared as in [4,5,6,7,8] and [13,14,15,16,17,18,19] and inverse of new definitions as in [10,12]. Also, there is a study of domination polynomial of certain graph as in[21,22,23]. The domination brings together many fields as labeled graph [2,3], topological graph [15], fuzzy graph [24,25] and others. The first introduced this concept is C. Berge in his book [9] and Ore is the first used in [20]. In this work, our viewpoint sheds a light on the new parameter of domination, and it is called equally co-neighborhood domination. When forming a group of workers to dominate the completion of work in most life problems, we usually seek to distribute the tasks between the group members equally. And the formation of another reserve group, be completely separate from the first group of workers to dominate the completion of work, and also the distributing of tasks between the group members equally, if the first group fails. From this principle, we set out to present this inverse new definition. There are some

properties and boundaries of this parameter that have been presented in this work. Also, domination number has been calculated for this definition IENDS for certain graphs as a complete, path, cycle, wheel, star, and complete bipartite graphs. Furthermore, an inverse equality co-neighborhood domination number for the graph that are obtained form three kinds of operations in graphs as the complement of a graph, the join of two graphs, and the corona of two graphs have been discussed with some properties.

To prove our main results we need the following results

Definition.1.1[1]. Let G be a simple graph, a proper subset $D \subset V$ is called equally co-neighborhood dominating set of *G* (*ENDS*), if every vertex in set *D* is adjacent to equally number of vertices in $V - D$. The set *D* is called minimal ENDS($MENDS$) if it has no proper *ENDS.* The equally domination number denoted by $\gamma_{en}(G)$ for simplicity $\gamma_{en}(G)$ is the minimum cardinality of a $MENDS$. The $MENDS$ of cardinality γ_{en} is called γ_{en}- *set.*

Proposition 1.2.[5]. A cycle C_n, $n \geq 3$ has $\gamma_{bi}(C_n) = \gamma_{bi}^{-1}(C_n) = \left\lceil \frac{n}{3} \right\rceil$

Corollary 1.3. [1]. For path P_n, $n \geq 3$ has no inverse bi-dominating set.

Proposition 1.4.[1]. Let G be a graph of order n, then

1) $\deg(v_i) \geq k, \forall v_i \in D$, where k is the number of vertices in $V - D$ that are adjacent to v_i.
2) If G has an isolated vertex, then G has no ENDS.
3) $1 \leq \gamma_{en}(G) \leq n - 1$.
4) The dominating set D is minimal if there is no adjacent vertex in to other vertices in D and has no private vertex in $V - D$.

Proposition 1.5. [1]. Let G be a graph of order n, then

1. A cycle C_n, $n \geq 3$ has $\gamma_{en}(C_n) = \gamma_{bi}(C_n) = \left\lceil \frac{n}{3} \right\rceil$.
2. For path P_n , $n \geq 3$,$\gamma_{en}(P_n) = \left\lceil \frac{n}{3} \right\rceil$.
3. For complete K_n , wheel W_n, and star S_n ,$\gamma_{en}(k_n) = \gamma_{en}(W_n) = \gamma_{en}(S_n) = 1$.

Proposition 1.6. [1]. For a complete bipartite graph $K_{n,m}$
$\gamma_{en}(K_{n,m}) = \min\{m, n, 2 + (\max\{m, n\} - \min\{m, n\})\}$.

Theorem 1.7. [1]. For path P_n , $n \geq 4$,$\gamma_{en}(\overline{P_n}) = 2$

Theorem 1.8. [1]. For a complete bipartite graph $K_{n,m}$ $\gamma_{en}(\overline{K_{n,m}}) = \max\{m, n\} - \min\{m, n\} + 2$.

Theorem 1.9. [1]. If G_1 and G_2 are two graphs with vertex sets V_1 and V_2 respectively and have no isolated vertex, then

$$\gamma_{FD}(G_1 + G_2) = \min\left\{\begin{array}{c}\left\{\begin{array}{c}\min\{\gamma_{FD}(G_1), \gamma_{FD}(G_1)\}, \text{ if } G_1 \text{ and } G_2 \text{ have MENDS,} \\ \gamma_{FD}(G_i, i \text{ either 1 or 2}), \text{if } G_i \text{ has MENDS and the others has no MENDS,} \\ \min\{|V_1|, |V_2|\}, \quad \text{if } G_1 \text{ and } G_2 \text{ have no MENDS and there is no vertex adjacent to all vertices in each graph}\end{array}\right\}, \\ |S|, \text{where S is the minimum set has the vertices from } G_1 + G_2 \text{ such that } S \cap V_1 \neq \emptyset \neq S \cap V_2 \text{and } N(v_i) \cap V - D \text{ is equal } \forall v_i \in S\end{array}\right\}$$

Theorem 1.10. [1]. If G_1 and G_2 be two graphs such that $\overline{G_1}$ and $\overline{G_2}$ have γ_{en}-set, then $\gamma_{en}(\overline{G_1 + G_2}) = \gamma_{en}(\overline{G_1}) + \gamma_{en}(\overline{G_2})$

Theorem 1.11. [1]. If G_1 and G_2 are two graphs, then in general
1) $\gamma_{en}(G_1 \odot G_2) = |G_1|$. 2) $\gamma_{en}(G_2 \odot G_1) = |G_2|$.

2 Inverse equally co-neighborhood domination number

Definition 2.1. Let $D \subset V$ is minimum equality co-neighborhood dominating set of G (MENDS), if $V - D$ contains a ENDS in G, this set is called an inverse equality co-neighborhood dominating set of D in G (IENDS) and denoted by D^{-1}. The inverse equality co-neighborhood dominating set number of G, denoted by $\gamma_{en}^{-1}(G)$ is the minimum cardinality over all inverse equality co-neighborhood dominating set in G. See Fig 1.

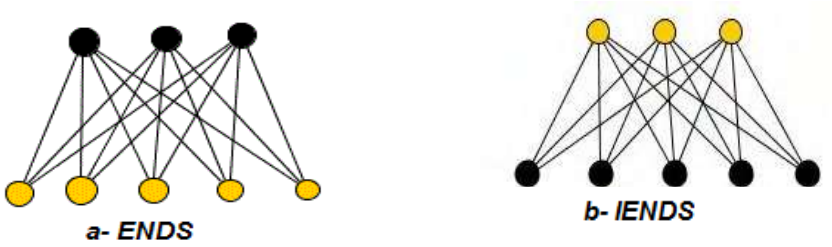

Figure (1): a-equally co-neighborhood dominating set and b-inverse equality co- neighborhood dominating set

Proposition 2.2. Let G be a graph having an MIENDS $\gamma_{en}^{-1}(G)$, then
1) $\gamma_{en}^{-1}(G) \geq \gamma_{en}(G)$
2) $\gamma_{en}^{-1}(K_n) = \gamma_{en}(K_n) = 1 \ \forall\, n \geq 2$
3) $\gamma_{en}^{-1}(S_n) = n - 1 \ \forall\, n \geq 3$
4) $1 \leq \gamma_{en}^{-1}(G) \leq n - 1$.

Proof.
1) by Definition 2.1 we get $\gamma_{en}^{-1}(G) \geq \gamma_{en}(G)$
2) It is clear since every vertex in K_n is adjacent to all the verticesK_n in the graph.
3) Since $\gamma_{en}(S_n)$-set is the center of the star $\forall\, n \geq 2$ then the set of all other vertices is MIENDS, therefore $\gamma_{en}^{-1}(S_n) = n - 1$
4) The lower bound occurs by 2, while the upper bound occurs by 3. □

Note 2.3. For any graph G of order n, and has ENDS, if $\gamma_{en}(G_n) > \frac{n}{2}$, then G has no IENDS.

Proposition 2.4. Let G be a graph of order n, then
1. A cycle C_n, $n \geq 3$ has $\gamma_{en}(C_n) = \gamma_{en}^{-1}(C_n) = \left\lceil \frac{n}{3} \right\rceil$
2. A wheel W_n, for $W_n = C_n + K_1$, $n \geq 3$, then $\gamma_{en}^{-1}(W_n) = \left\lceil \frac{n}{3} \right\rceil$

Proof.
1. Since deg(v) = 2, $\forall\, v \in C_n$ and $\gamma_{bi}(C_n) = \gamma_{bi}^{-1}(C_n) = \left\lceil \frac{n}{3} \right\rceil$ and $\gamma_{en}(C_n) = \gamma_{bi}(C_n) = \left\lceil \frac{n}{3} \right\rceil$ by Proposition 1.2 and Proposition 1.5, then $\gamma_{en}(C_n) = \gamma_{en}^{-1}(C_n) = \left\lceil \frac{n}{3} \right\rceil$.

2. Let D be MENDS in W_n, since $\gamma_{en}(W_n) = 1$ and $W_n = C_n + K_1$. So, $D = \{v\}, v \in K_1$, and $vu \in E(W_n)\ \forall u \in V - D$, then $\gamma_{en}(C_n)$-set is a MIENDS of D in W_n. Therefore, $\gamma_{en}^{-1}(W_n) = \gamma_{en}(C_n) = \left\lceil \frac{n}{3} \right\rceil$. □

Theorem 2.5. Let G be graph has D is MENDS, then G has no IENDS if contains pendant vertex $v \notin D$, and $\langle V - D \rangle$ has isolated vertex is not pendant vertex in G.

Proof.
Let G be a graph having D which is a MENDS and let $v \notin D$, be a pendant vertex in G and u is isolated vertex in $V - D$, such that $v \neq u$. The vertex v is adjacent to only one vertex in D and u is adjacent to at least two vertices in D. Then every dominating set $\widetilde{D}$, such that $\widetilde{D} \cap D = \emptyset$ contains v and u, then $\widetilde{D}$ is not ENDS. Thus, the proof is done. □

Theorem 2.6. Let P_n be a path graph of order $n \geq 2$, then

1. If $n \equiv 0 (\mathrm{mod}\ 3)$, then $\gamma_{en}^{-1}(P_n) = \frac{2n}{3}$
2. If $n \equiv 1, 2 (\mathrm{mod}\ 3)$, such that $n \geq 5$, then P_n has no IENDS.
3. $\gamma_{en}^{-1}(P_2) = 1$ and $\gamma_{en}^{-1}(P_4) = 2$

Proof.
Let P_n be a path graph of order n, and D be a MENDS, then we have $\gamma_{en}(P_n) = |D| = \left\lceil \frac{n}{3} \right\rceil$, by Proposition 1.5, then

1. If $n \equiv 0 (\mathrm{mod}\ 3)$, hence $\gamma_{en}(P_n) = \frac{n}{3}$, i.e. we have one vertex in D that is adjacent to two vertices in $V - D$ for every three vertices in P_n, then $N(v) \cap N(u) = \emptyset$ in $V - D\ \forall v, u \in D$, then every vertex in $V - D$ is adjacent to only one vertex in D. Hence, $V - D$ is IENDS in P_n and it is MIENDS, because $\langle V - D - \{p\} \rangle\ \forall\ p \in (V - D)$ is not IENDS for two subcases are obtained as follows.
   I. The vertex p is pendant, then the set $V - D - \{p\}$ has no vertex dominated to p
   II. The vertex p is not a pendant vertex, then $V - D - \{p\}$ has one vertex u that is adjacent to p and D has one vertex v which is adjacent to u, then u is an isolated vertex in $\langle V - D - \{p\} \rangle$. Therefore $V - D - \{p\}$ is not IENDS according to Theorem 2.5, since $\gamma_{en}(P_n) = |D| = \frac{n}{3}$, then $\gamma_{en}^{-1}(P_n) = |V - D| = \frac{2n}{3}$
2. It is straightforward from II in (1) and according to Theorem 2.5
3. Let $P_2 = \{v, u\}$, then $D = \gamma_{en}(P_2) - \text{set} = \{v\}$, $V - D = \gamma_{en}^{-1}(P_2) - \text{set} = \{u\}$.

And let $P_4 = \{v_1, v_2, v_3, v_4\}$, then $D = \gamma_{en}(P_2) - \text{set} = \{v_1, v_4\}$, $V - D = \gamma_{en}^{-1}(P_2) - \text{set} = \{v_2, v_3\}$ or vice versa. Thus, the proof is done. □

Proposition 2.7. Let $K_{n,m}$ be a complete bipartite graph for $m \geq n \geq 2$, then

$$\gamma_{en}^{-1}(K_{n,m}) = \begin{cases} |m - n| + 2 \text{ if } |m - n| + 2 \leq \min, \text{and } \gamma_{en}(K_{n,m}) = m - n + 2 \\ \max\{m, n\} \text{ if } |m - n| + 2 \geq \min\{m, n\}, \text{and } \gamma_{en}(K_{n,m}) = \min\{m, n\} \end{cases}$$

Proof.
Let X and Y are the partite sets of the vertices of $K_{n,m}$, such that $|X| = n$ and $|Y| = m$ and let $m \geq n \geq 2$. Two cases are obtained as follows.

1. If $n = m$, then each vertex in G has the same degree, hence $\gamma_{en}(K_{n,m})$ −set=$\{v_1, u_1\}$, where $v_1 \in X$ and $u_1 \in Y$, and we have $\gamma_{en}^{-1}(K_{n,m}) - \text{set} = \{v_2, u_2\}$, where $v_2 \in X$ and $u_2 \in Y$, such that $v_1 \neq v_2$ and $u_1 \neq u_2$

2. If $n \neq m$, then to keep that each vertex in set D has the same neighborhood in $V - D$, then the vertices in the set D must be either set X or the set Y or set $S = \{v_i : v_i \in Y, i = 1,2, \dots, m - n\} \cup \{v, u\}$, such that $v \in X$ and $u \in Y$ and $u \neq v_i$. The set S has $m - n + 2$ vertices. Since $m \geq n \geq 2$, hence $m - n + 2 \leq m$ and $\gamma_{en}(K_{n,m}) = \min\{n, m - n + 2\}$. Then three subcases are obtained as follows.

I. When $m - n + 2 = n$, then $\gamma_{en}(K_{n,m}) = m - n + 2$ or $\gamma_{en}(K_{n,m}) = n$ and there are at least $m - n + 2$ vertices in $V - D$, such that one vertex from X and $m - n + 1$ from Y. Therefore $\gamma_{en}(K_{n,m}) = m - n + 2 = \gamma_{en}^{-1}(K_{n,m}) = m - n + 2$, or $\gamma_{en}(K_{n,m}) = n$ and $\gamma_{en}^{-1}(K_{n,m}) = m$

II. When $m - n + 2 < n$, then $\gamma_{en}(K_{n,m}) = m - n + 2$ and there are at least $m - n + 2$ vertices in $V - D$, such that one vertex from X and $m - n + 1$ from Y. Therefore $\gamma_{en}(K_{n,m}) = \gamma_{en}^{-1}(K_{n,m}) = m - n + 2$.

III. When $m - n + 2 > n$, then $\gamma_{en}(K_{n,m}) = n$, therefore $\gamma_{en}^{-1}(K_{n,m}) = m$.

Thus proof is done. □

3 Inverse equally co-neighborhood domination number in some graphs

3.1 The complement of certain graphs

Proposition 3.1.1. Let G be a graph of order n, If $\gamma_{en}(G) = 1$, then $\overline{G}$ has no IENDS..

Proof.

Since $\gamma_{en}(G) = 1$, then G has vertex that is adjacent to all other vertices in G, hence $\overline{G_n}$ has an isolated vertex. Therefore, it has no ENDS and IENDS. □

Proposition 3.1.2 .

1. For path P_n , $n \geq 4$, $\gamma_{en}^{-1}(\overline{P_n}) = 2$.
2. For cycle C_n , $n \geq 4$, $\gamma_{en}^{-1}(\overline{C_n}) = 2$.

Proof.

1. By Theorem 1.7, $\gamma_{en}(\overline{P_n}) = 2$, $\gamma_{en}(\overline{P_n})$-set has two vertices which are pendant vertices in P_n, since any others two vertices, which are adjacent vertices and are not pendant vertices in P_n are adjacent with all vertices in $\overline{P_n}$, then $\gamma_{en}^{-1}(\overline{P_n}) = 2$ and vice versa.
2. By Theorem 6 [1], $\gamma_{en}(\overline{C_n}) = 2$, $\gamma_{en}(\overline{C_n})$-set has two vertices in C_n, which are adjacent vertices in C_n, since any others two adjacent vertices in C_n are adjacent with all vertices in $(\overline{C_n})$, then $\gamma_{en}^{-1}(\overline{C_n}) = 2$. □

Theorem 3.1.3. Let $K_{n,m}$ be a complete bipartite graph for $m \geq n \geq 2$, then

1. $\gamma_{en}^{-1}(\overline{K_{n,m}}) = |m - n| + 2$ if $|m - n| + 2 \leq \min\{m, n\}$
2. $K_{n,m}$ has no IENDS if $|m - n| + 2 > \min\{m, n\}$

Proof

It is obvious that $\overline{K_{m,n}} \equiv K_m \cup K_n$, let $m \geq n \geq 2$ and let D be $\gamma_{en}(\overline{K_{n,m}})$-set. Must be D has one vertex from K_n and $m - n + 1$ vertices from K_m, according to Definition 1.1, ie $|D| = \gamma_{en}(\overline{K_{n,m}}) = m - n + 2$, and $|V - D| = 2(n - 1)$, such that (n-1) vertices from K_n and (n-1) vertices from K_m. Then two cases are obtained as follows.

Case 1. If $m - n + 2 \leq n$, then $m \leq 2(n - 1)$, since $|D| = m - n + 2$, then $|D| \leq |V - D|$, and since $m \geq n \geq 2$, then in this case we have one vertex from K_n and $m - n + 1$ vertices from K_m in $V - D$. Therefore $\gamma_{en}^{-1}(\overline{K_{n,m}}) = |m - n| + 2$

Case 2. If $m - n + 2 > n$, then $m > 2(n-1)$, since $|D| = m - n + 2$, then $|D| > |V - D|$. Therefore $K_{n,m}$ has no IENDS, according to Note 2.3. □

3.2 IENDS of Join Graphs

Theorem 3.2.1. If G_1 and G_2 are two graphs with vertices sets V_1 and V_2 respectively and have no isolated vertex, then $\gamma_{en}^{-1}(G_1 + G_2) =$

$$\min\left\{\begin{array}{l}\left\{\begin{array}{l}\left\{\begin{array}{l}\{\gamma_{en}(G_1), \text{or } \gamma_{en}(G_2)\}, \text{ when } \gamma_{en}(G_1) = \gamma_{en}(G_2), \text{ if } G_1 \text{ and } G_2 \text{ have IENDS,}\\ \min\{\gamma_{en}^{-1}(G_1), \gamma_{en}(G_2)\}, \text{ when } \gamma_{en}(G_1) < \gamma_{en}(G_2), \text{ if } G_1 \text{ and } G_2 \text{ have IENDS,}\\ \min\{\gamma_{en}(G_1), \gamma_{en}^{-1}(G_2)\}, \text{when } \gamma_{en}(G_1) > \gamma_{en}(G_2), \text{if } G_1 \text{ and } G_2 \text{ have MENDS.}\end{array}\right.\\ \left\{\begin{array}{ll}\min\{\gamma_{en}^{-1}(G_1), |V_2|\}, & \text{when } \gamma_{en}(G_1) < |V_2|, \text{if } G_1 \text{ has IENDS and the others has no ENDS,}\\ \gamma_{en}(G_1), & \text{when } \gamma_{en}(G_1) > |V_2|, \text{if } G_1 \text{ has IENDS and the others has no ENDS.}\end{array}\right.\\ \max\{|V_1|, |V_2|\}, \quad \text{if } G_1 \text{ and } G_2 \text{ have no MENDS and there is no vertex adjacent to all vertices in each graph}\end{array}\right.\\ |S^{-1}|, \text{where S is the minimum set has the vertices from } G_1 + G_2 \text{ such that } S \cap V_1 \neq \emptyset \neq S \cap V_2 \text{and } N(v_i) \cap V - D \text{ is equal } \forall v_i \in S\end{array}\right\}$$

Proof.

Let G_1 and G_2 two graphs of order $|V_1|$ and $|V_2|$ respectively, and with no isolated vertex, then according to Theorem 1.9 there are two cases depend on the vertices of MIENDS taken form only one graph or both as follows.

Case 1. There are three subcases as follows.

1. When G_1 and G_2 have IENDS, in this case there are the following.

I. If $\gamma_{en}(G_1) = \gamma_{en}(G_2)$, then one of them is $\gamma_{en}(G_1 + G_2)$ and other is, $\gamma_{en}^{-1}(G_1 + G_2)$.

II. If $\gamma_{en}(G_1) < \gamma_{en}(G_2)$, then it must be $\gamma_{en}(G_1 + G_2) = \gamma_{en}(G_1)$, hence $\gamma_{en}^{-1}(G_1 + G_2) = \min\{\gamma_{en}^{-1}(G_1), \gamma_{en}(G_2)\}$

III. If $\gamma_{en}(G_1) > \gamma_{en}(G_2)$, then $\gamma_{en}^{-1}(G_1 + G_2) = \min\{\gamma_{en}(G_1), \gamma_{en}^{-1}(G_2)\}$ is true according to (ii).

2. If G_1has IENDS and G_2 has no ENDS, Since vertices set of V_2 is ENDS for $(G_1 + G_2)$, then $\gamma_{en}(G_1 + G_2) = \min\{\gamma_{en}(G_1), |V_2|\}$ and $\gamma_{en}^{-1}(G_1 + G_2) = \min\{\gamma_{en}^{-1}(G_1), |V_2|\}$, when $\gamma_{en}(G_1) < |V_2|$ ie $\gamma_{en}(G_1 + G_2) = \gamma_{en}(G_1)$, while $\gamma_{en}^{-1}(G_1 + G_2) = \gamma_{en}(G_1)$ when $\gamma_{en}(G_1) > |V_2|$ ie $\gamma_{en}(G_1 + G_2) = |V_2|$.

3. If G_1 and G_2 have no ENDS, also they have no IENDS, then $\gamma_{en}(G_1 + G_2)$ =min $\{|V_1|, |V_2|\}$ and $\gamma_{en}^{-1}(G_1 + G_2)$= max $\{|V_1|, |V_2|\}$.

case 2. When S is the minimum set has the vertices from $G_1 + G_2$ such that $S \cap V_1 \neq \emptyset \neq S \cap V_2$ and vertices number of the set $N(v_i) \cap V - D$ are equal $\forall v_i \in S$, then $\gamma_{en}(G_1 + G_2) = |S|$ and $\gamma_{en}^{-1}(G_1 + G_2) = |S^{-1}|$. Therefore, $\gamma_{en}^{-1}(G_1 + G_2) = \min\{\text{case 1, case 2}\}$. The proof is done. □

Corollary 3.2.2. Let G_1 and G_2 are two isomorphic graphs, then $\gamma_{en}^{-1}(G_1 + G_2)$=2.

Proof.

If G_1 is isomorphic to G_2, then every vertex in G_1 is adjacent to all vertices in G_2 and every vertex in G_2 is adjacent to all vertices in G_1, and V (G_1) = V (G_1), then $\gamma_{en}(G_1 + G_2) = \gamma_{en}^{-1}(G_1 + G_2)$=2. □

Proposition 3.2.3. If G_1 and G_2 are two graphs such that $\overline{G_1}$ and $\overline{G_2}$ have IENDS,, then $\gamma_{en}^{-1}(\overline{G_1 + G_2}) = \gamma_{en}^{-1}(\overline{G_1}) + \gamma_{en}^{-1}(\overline{G_2})$.

Proof.

Since $\overline{G_1 + G_2}$ is isomorphic to $\overline{G_1} \cup \overline{G_2}$ and $\gamma_{en}(\overline{G_1 + G_2}) = \gamma_{en}(\overline{G_1}) + \gamma_{en}(\overline{G_2})$ according to Theorem 1.10, then $\gamma_{en}^{-1}(\overline{G_1 + G_2}) = \gamma_{en}^{-1}(\overline{G_1}) + \gamma_{en}^{-1}(\overline{G_2})$. □

3.3 IENDS of Corona Graphs

Theorem 3.3.1. If G_1 and G_2 are two graphs of order $|G_1|$=n and $|G_1|$ =m respectively such that G_1 and G_2 have IENDS, then we have.

1. $\gamma_{en}^{-1}(G_1 \odot G_2) = n\,\gamma_{en}(G_2)$
2. $\gamma_{en}^{-1}(G_2 \odot G_1) = m\,\gamma_{en}(G_1)$

Proof.

Let G_1 and G_2 are two graphs, then

1. By definition of corona graph in graph $G_1 \odot G_2$ we have one copy of G_1 and n copies of G_2. each i^{th} vertex in the graph G_1 is adjacent to all vertices in the i^{th} copy of G_2. And according to Theorem 1.11 , $\gamma_{en}(G_1 \odot G_2) = |G_1|$. Therefore, $\gamma_{en}^{-1}(G_1 \odot G_2) = n\,\gamma_{en}(G_2)$
2. The proof is By the same method in 1. □

Corollary 3.3.2.

1. $\gamma_{en}(\overline{G_1} \odot \overline{G_2}) = |G_1|$.
2. $\gamma_{en}^{-1}(\overline{G_1} \odot \overline{G_2}) = n\,\gamma_{en}(\overline{G_2})$.

Proof.

1. Let G_1 and G_2 are two graphs, and $|D| = \gamma_{en}(G_1 \odot G_2) = |G_1|$ according to Theorem 1.11 and since $\overline{G_1}$and $\overline{G_2}$ be new graphs and $|\overline{G_1}| = |G_1|$, then $\gamma_{en}(\overline{G_1} \odot \overline{G_2}) = |\overline{G_1}| = |G_1|$.
2. By definition of corona graph and according to 1 in above , then $V - D = n|G_2|$. Therefore, $\gamma_{en}^{-1}(\overline{G_1} \odot \overline{G_2}) = n\,\gamma_{en}(\overline{G_2})$. □

Proposition 3.3.3. If G_1 and G_2 are two graphs of order $n \geq 2$ and $m \geq 2$ respectively such that $\overline{G_1}$and $\overline{G_2}$ have IENDS, then $\gamma_{en}^{-1}(\overline{G_1 \odot G_2}) = \gamma_{en}(\overline{G_1 \odot G_2}) = 2$.

Proof.

Let G_1 and G_2 are two graphs of order $n \geq 2$ and $m \geq 2$ respectively , then we have every vertex in i^{th} copy of G_2 is adjacent to at least all the vertices in $(\overline{G_1 \odot G_2})$ except i^{th} vertex in G_1 and all other vertices in same copies of G_2. Let $D = \{v, u: v \text{ in } i^{th} \text{ copy of } G_2 \text{ and } u \text{ in } (i+1)^{th} \text{copy of } G_2\}$, then by the above set D is $\gamma_{en}(\overline{G_1 \odot G_2})$-set. And since $n \geq 2$ and $m \geq 2$, then other two vertices have the same conditions as v and u but different from them. Therefore, $\gamma_{en}^{-1}(\overline{G_1 \odot G_2}) = \gamma_{en}(\overline{G_1 \odot G_2}) = 2$. □

4 Conclusion

In this work, the new notion of inverse domination has been introduced for the different types of graphs. Also, some advanced properties through different proved theorems are added. And obtained the lower and upper bound of the inverse equally co-neighborhood domination number. Also, determined this definition to certain graphs like a cycle, wheel, path complete, and complete bipartite. Finally, we performed some operations on a graph and a certain graph, and these are the complement of a certain graph, join to two graphs, and corona of two graphs.

A New Algorithm to Estimate the Parameters of Log-Logistic Distribution Based on the Survival functions

A New Algorithm to Estimate the Parameters of Log-Logistic Distribution Based on the Survival functions

Amina Ibrahim k. and Bayda Atiya Kalaf

E-mail: hbama75@yahoo.com

Abstract. Estimation of the parameters is quite important in the numerous fields for the development of mathematical models. Maximum likelihood estimation is a good method, which is usually used to elaborate on the parameter estimation. The likelihood function formed for the parameter estimation of Log-Logistic is very hard to maximize. Therefore, this paper proposes a new hybrid of Maximum Likelihood Estimator (MLE) and Simplex Downhill Algorithm (SDA) called (MLESDA) to estimate parameters of Log-Logistic distribution based on Survival functions. To compare the suggested method (MLESDA) and classical Maximum Likelihood (MLE) method, simulation is used. The results demonstrate that MLESDA is more efficient than the MLE method.

1. Introduction

Recently, Survival Analysis (SA) is one of the widely used techniques in medical statistics, physics, medicine, epidemiology engineering, economics, biology, and public health [1, 2]. Estimating survival functions that have interested statisticians for numerous years.

The most of the existing books of Survival analysis for Kleinbaum and Klein [4], Allison [5] introduced this topic from a conventional statistical scene instead of a machine learning standpoint. Chung et al. [3] described the statistical methods of survival analysis and their implementation in criminology for predicting the time until recidivism. Recently, Cruz and Wishart [6] and Kourou et al. [7] discussed applications in cancer prediction and used several survival analysis methods.

The log-logistic distribution possesses a rather supple functional form [8]. The log-logistic distribution has its own standing as a life testing model; it is viewed as a weighted exponential distribution and also is an increasing failure rate (IFR) model. Due to the importance of this distribution in reliability, it has been used to estimate the estimators to find parameters. This distribution and for the adoption process to assess the estimators of those two parameters have been estimated the survival of this distribution.

The nonlinearity model makes the estimation of parameter and the statistical analysis of parameter estimates more difficult and challenging.

Although, SDA algorithm still a good choice for many practitioners in the fields of physical, statistical, medical sciences, and engineering. Since, it is very easy to use and code [9, 10]. However, until now SDA has not been applied in many mathematical problems. Therefore, in this paper, simplex downhill algorithm adopted to estimate the parameters of Log-Logistic distribution based on Survival functions.

The organized paper as follows: section 2 offers some information about Log Logistic distribution. Section 3. is clarifying Maximum likelihood Estimation method. Section 4 describe the proposed

method (MLEDSA). Section 5 Simulation study. Section 6 demonstrates the effectiveness of the proposed method through numerical results. Finally, in Section 6 a conclusion is provided.

2. Log-Logistic Distribution

The probability density function (p. d. f) and the cumulative distribution function (c. d. f) of Log Logistic distribution are expressed respectively as:

$$f(x,a,\beta)=\frac{\frac{\beta}{a}(\frac{x}{a})^{\beta-1}}{(1+(\frac{x}{a})^{\beta})^{2}} \quad (1)$$

$$F(x,a,\beta)=\frac{1}{1+(\frac{x}{a})^{-\beta}} \quad (2)$$

where x is a value of random variable, α is scale parameter, and β is shape parameter and $a,\beta > 0$.

$$S(x)=1- F(x,a,\beta) \quad (3)$$

The survival function $S(x)$ for the Log-Logistic distribution given by substituting equation (2) in equation (3), as follows:

$$S(x)=1-\frac{1}{1+(\frac{x}{a})^{-\beta}}$$

$$S(x)=\frac{1}{1+(\frac{x}{a})^{\beta}} \quad (4)$$

3. Maximum Likelihood Estimation Method (MLE):

Let $X_{(1)},X_{(2)},\dots,X_{(n)}$ be order random sample of sized (n) from a distribution with *p.d.f* $f(x,a,\beta)$ such that (a,β) are the parameters, then the likelihood function $L(a,\beta)$ is the joint *p.d.f* of the random samples is [11]:

$$L\left(x_{(1)},x_{(2)},\dots,x_{(n)},a,\beta\right)=\prod_{i=1}^{n}f(x_i)=\prod_{i=1}^{n}\left(\frac{\frac{\beta}{a}\left(\frac{x_{(i)}}{a}\right)^{\beta-1}}{\left(1+\left(\frac{x_{(i)}}{a}\right)^{\beta}\right)^{2}}\right)$$

$$=\frac{\beta^{n}}{a^{n}}\prod_{i=1}^{n}\left(\frac{\left(\frac{x_{(i)}}{a}\right)^{\beta-1}}{\left(1+\left(\frac{x_{(i)}}{a}\right)^{\beta}\right)^{2}}\right) \quad (5)$$

Taking the natural logarithm for the equation (5), so we get the function:

$$LnL\left(x_{(i)},a,\beta\right)=nLn\left(\frac{\beta}{a}\right)+(\beta-1)\sum_{i=1}^{n}Ln(\frac{x_{(i)}}{a})-2\sum_{i=1}^{n}Ln\left(1+\left(\frac{x_{(i)}}{a}\right)^{\beta}\right)$$

$$LnL\left(x_{(i)},a,\beta\right)=nLn(\beta)-nLn(a)+\beta\sum_{i=1}^{n}Ln\left(\frac{x_{(i)}}{a}\right)-\sum_{i=1}^{n}Ln\left(\frac{x_{(i)}}{a}\right)-2\sum_{i=1}^{n}Ln\left(1+\left(\frac{x_{(i)}}{a}\right)^{\beta}\right)$$

$$LnL\left(x_{(i)},a,\beta\right)=nLn(\beta)-nLn(a)+\beta\sum_{i=1}^{n}Ln\left(x_{(i)}\right)-\beta\sum_{i=1}^{n}Ln(a)-\sum_{i=1}^{n}Ln\left(x_{(i)}\right)+\sum_{i=1}^{n}Ln(a)-2\sum_{i=1}^{n}Ln\left(1+\left(\frac{x_{(i)}}{a}\right)^{\beta}\right) \quad (6)$$

The partial derivative for the equation (6) with respect to the unknown parameters (α,β), respectively:

$$\frac{\partial\, LnL\,(x_{(i)},a,\beta)}{\partial a} = \frac{-n}{\alpha} - \beta\sum_{i=1}^{n}\frac{1}{\alpha} + \sum_{i=1}^{n}\frac{1}{\alpha} - 2\sum_{i=1}^{n}\frac{\beta\left(\frac{x_{(i)}}{\alpha}\right)^{\beta-1}\left(\frac{-x_{(i)}}{\alpha^2}\right)}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}}$$

$$\frac{\partial\, LnL\,(x_{(i)},a,\beta)}{\partial a} = \frac{2\beta}{\alpha}\sum_{i=1}^{n}\frac{\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}} - \frac{n\beta}{\alpha} \tag{7}$$

Set equation (7) equal to zero , we get

$$\frac{2\beta}{\alpha}\sum_{i=1}^{n}\frac{\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}} - \frac{n\beta}{\alpha} = 0 \tag{8}$$

$$\frac{\partial\, LnL\,(x_{(i)},a,\beta)}{\partial \beta} = \frac{n}{\beta} + \sum_{i=1}^{n} Ln\left(\frac{x_{(i)}}{\alpha}\right) - 2\sum_{i=1}^{n}\frac{\left(\frac{x_{(i)}}{\alpha}\right)^{\beta} Ln\left(\frac{x_{(i)}}{\alpha}\right)}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}} \tag{9}$$

After putting equation (9) to zero, then

$$\frac{n}{\beta} + \sum_{i=1}^{n} Ln\left(\frac{x_{(i)}}{\alpha}\right) - 2\sum_{i=1}^{n}\frac{\left(\frac{x_{(i)}}{\alpha}\right)^{\beta} Ln\left(\frac{x_{(i)}}{\alpha}\right)}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}} = 0 \tag{10}$$

Numerical technique for this method which is *Newton Raphson method* has been used.
From equation (8), we get:

$$2\sum_{i=1}^{n}\frac{\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}} - n = 0 \tag{11}$$

Let $f_1(\alpha,\beta)$ is define of equation (11), we get:

$$f_1(\alpha,\beta) = 2\sum_{i=1}^{n}\frac{\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}} - n \tag{12}$$

From equation (9), we get:

$$\frac{n}{\beta} + \sum_{i=1}^{n} Ln\left(\frac{x_{(i)}}{\alpha}\right) - 2\sum_{i=1}^{n}\frac{Ln\left(\frac{x_{(i)}}{\alpha}\right)}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{-\beta}} = 0 \tag{13}$$

Let $g_1(\alpha,\beta)$ define of equation (13), we get:

$$g_1(a,\beta) = \frac{n}{\beta} + \sum_{i=1}^{n} Ln\left(\frac{x_{(i)}}{\alpha}\right) - 2\sum_{i=1}^{n}\frac{Ln\left(\frac{x_{(i)}}{\alpha}\right)}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{-\beta}} \tag{14}$$

Since the two-nonlinear equations are complicated to be solved, it is impossible to find estimators of parameters (α,β). For this reason using the numerical analysis (iterative method) to obtain and estimate (α,β) which maximizes the likelihood function. One of these numerical procedures is Newton-Raphson method [12]. It is one of the important methods in numerical analysis because it is very fast and the error

of this iterative method is quadratic approximation. In Newton-Raphson method using the Jacobean matrix J_i which is the first derivatives for each equation of $f_1(\alpha,\beta)$ and $g_1(\alpha,\beta)$ with respect to α and β.

Now, we find the formulas of Jacobean matrix as follows:

$$J = \begin{vmatrix} \frac{\partial f_1(\alpha,\beta)}{\partial \alpha} & \frac{\partial f_1(\alpha,\beta)}{\partial \beta} \\ \frac{\partial g_1(\alpha,\beta)}{\partial \alpha} & \frac{\partial g_1(\alpha,\beta)}{\partial \beta} \end{vmatrix}$$

$$\frac{\partial f_1(\alpha,\beta)}{\partial \alpha} = -2\frac{\beta}{\alpha}\sum_{i=1}^{n}\frac{1}{\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{-\beta}\right)\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}\right)} \quad (15)$$

$$\frac{\partial f_1(\alpha,\beta)}{\partial \beta} = 2\frac{\beta}{\alpha}\sum_{i=1}^{n}\frac{Ln\left(\frac{x_{(i)}}{\alpha}\right)}{\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{-\beta}\right)\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}\right)} \quad (16)$$

and,

$$\frac{\partial g_1(\alpha,\beta)}{\partial \alpha} = \frac{n}{\alpha} + \frac{2}{\alpha}\sum_{i=1}^{n}\frac{1}{1+\left(\frac{x_{(i)}}{\alpha}\right)^{-\beta}} + \frac{2\beta}{\alpha}\sum_{i=1}^{n}\frac{Ln\left(\frac{x_{(i)}}{\alpha}\right)}{\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{-\beta}\right)\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}\right)} \quad (17)$$

$$\frac{\partial g_1(\alpha,\beta)}{\partial \beta} = \frac{n}{\beta^2} - 2\sum_{i=1}^{n}\frac{Ln\left(\frac{x_{(i)}}{\alpha}\right)^2}{\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{-\beta}\right)\left(1+\left(\frac{x_{(i)}}{\alpha}\right)^{\beta}\right)} \quad (18)$$

Thus, the following equations matrixes are applied to estimate the parameters for Log-Logistic distribution by using Newton-Raphson method.

$$\begin{pmatrix}\hat{\alpha}_{MLE}\\ \hat{\beta}_{MLE}\end{pmatrix} = \begin{pmatrix}\alpha_0\\ \beta_0\end{pmatrix} - j^{-1}\begin{pmatrix}f_1(\alpha,\beta)\\ g_1(\alpha,\beta)\end{pmatrix} \quad (19)$$

Let

$$v_1 = \frac{\partial f_1(\alpha,\beta)}{\partial \alpha}, v_2 = \frac{\partial f_1(\alpha,\beta)}{\partial \beta}, v_3 = f_1(\alpha,\beta)$$
$$v_4 = \frac{\partial g_1(\alpha,\beta)}{\partial \alpha}, v_5 = \frac{\partial g_1(\alpha,\beta)}{\partial \beta}, v_6 = g_1(\alpha,\beta) \quad (20)$$

Now, substitute equation (19) in equation (20), we get:

$$\hat{\alpha}_{MLE} = \alpha_0 + h_1 \quad (21)$$
$$\hat{\beta}_{MLE} = \beta_0 + k_1 \quad (22)$$

where:

$h_1 = \frac{v_4 v_6 - v_3 v_5}{v_1 v_5 - v_2 v_4}$, and $k_1 = \frac{-v_3 - v_1 h_1}{v_4}$

So, to estimate the survival analyses $\hat{S}(x)$, we substitute equations (21) and (22) in equation (3).

4. Simplex Downhill Algorithm and Maximum Likelihood Estimation Method (MLEDHA)

Simplex downhill algorithm (SDA) was introduced in 1962 [13]. However, Nelder and Mead [14] modified this algorithm in 1965 to the modern form. SDA called Nelder-Mead or Amoeba. Simplex downhill algorithm is a mathematical method that uses geometric relationships to aid in finding approximate solutions to solve complex and optimization problems. The benefit of this method is it does not require an evaluation of the derivative of the function. But only guesses number of solutions for each decision variable. The idea of SDA generates $N + 1$ points (vertex) in an N-dimensional space. Then the vertices sorted by ascending order such as: $f(x_1) \leq f(x_2) \leq \ldots \leq f(x_n) \leq$

$f(x_{n+1})$, where x_{n+1} is worse solution and $x1$ best solution. The algorithm iteration updates to improve the worst solution by four operations as follows:

Reflection step:

compute the reflection point x_r from $x_r = m + \lambda\,(m - x_{n+1})$

and evaluate $f\ for\ x_r$,

where m is the centroid of the N best solution in the vertices of the simplex $m = mean\,(x\,((:n))$ and $\lambda = 1$.

$If\ f(x_1) \leq f(x_r) < f(x_n)$, ten put the worst solution in reflected point

$x_{n+1} = x_r$.

Expansion step:

If $f(x_r) < f(x_1)$ then generate a new point x_e by expansion, from

$x_e = x_r + \beta\,(x_r - m)$, where $\beta = 2$.

- If $f(x_e) < f(x_r)$ then replace x_{n+1} with x_e.
- else $x_{n+1} = x_r$.

Contraction step:

$If\ f(x_{n+1}) \leq f(xr), generate\ a\ new\ solution\ x_c$

$where\ x_c = m + \gamma\,(m - x_{n+1})$.

$If\ f(x_c) < f(xr)\quad then\ x_{n+1} = x_c$.

$else\ x_{n+1} = x_r$.

The step of shrinkage is used, if the three steps are failing in above.

Shrinkage Step:
We keep the best one x_1 then generate the n new vertices by using $x_{sj} = x_1 + \sigma\,(x_{sj} - x_1)$, j = {2 … n +1} and σ = 0.5. The next iteration consists of the simplex vertices as x_1, x_{s2}, …, $x_{s\ n+1}$.
The objective function of the simplex downhill algorithm in this method was the log likelihood function. By minimizing the log likelihood function, the SDA estimates the parameters of the Log-Logistic Distribution.

5. Simulation:

The estimation performance of the proposed method is verified through simulation in this section. In addition, each simulation condition was generated by 1000 replications. The simulation program was written by Matlab 2016. For examining the effect of sample size, various sample sizes are tested: 40, 80, and 100. The simulation steps as follows;

Step 1: Generate random samples as $u_1, u_2, \dots, u_n$, which are following the continuous uniform distribution defined on the interval (0,1). Then transform it to a random sample follows Log-Logistic distribution using $c.d.f.$ as follow;

$$F(x,a,\beta)=\frac{1}{1+(\frac{x_i}{a})^{-\beta}} \quad , \quad Ui=\frac{1}{1+(\frac{x_i}{a})^{-\beta}} \quad , \quad x_i=\ a(\frac{Ui}{1-Ui})^{\frac{1}{\beta}}$$

Then, let *G* is a vector of all parameters required, such as $G = [a, \beta\ ]$ and generate *k+1* solutions for *X*. where k i s t h e number of parameters t h a t required for output

Step 2: Recall the S from the equation (4).

Step 3: By (L=1000) replication, we compute $\hat{S}$ based on MLE using equations (21), and (22), and the best solution from (f_1) MLEDSA method.

6. Result of Simulation

In order to verify the performance of the MLEDSA method to estimate the parameters, we made simulation by examining various sample sizes (30, 60, 90) . We considered different values of parameters of (α, β) as (0.5 , 2), (2 , 4), (3 , 1), (1,0.5), (1,5) respectively. Based on MSE. Each table explained the result of estimate values of α and β, survival and estimate survival, respectively.

The following tables (1-5) showed that the proposed algorithm offered less MSE for estimate parameters and survival function. Therefore, MLEDSA method provides better results.

Table 1. MSE of estimate the parameters and survival analyses when $\alpha = 0.5\ and\ \beta = 2$

Simple size	Method	$\hat{\alpha}$	$\hat{\beta}$	S	$\hat{S}$
	MLE	0.47737	1.88420	0.50000	0.47820
$n = 30$	MLE/SDA	0.47806	1.92247	0.50000	0.48644
	MLE	0.56668	2.56315	0.50000	0.57342
$n = 60$	$MLE/\ SDA$	0.56609	2.45316	0.50000	0.57055

7. Conclusion

In this paper, a new algorithm MLESDA has been recommended to estimate the parameters for log logistic distribution based on survival analyses. Simulation is founded to compare between the suggested method and MLE. The results showed that MLESDA variant more precisely estimate the parameters than the MLE.

New restricted biased estimator based on modified unbiased ridge regression estimator

New restricted biased estimator based on modified unbiased ridge regression estimator

Bader Aboud Mohammad and Mustafa Ismaeel Naif

Department of Mathematics, College of education for pure science,
University Of Anbar, Anbar, Iraq

E-mail: bad19u2003@uoanbar.edu.iq

Abstract. More researchers used biased estimators instead of the restricted least square estimator (RLS) that is unbiased to improve the efficiency of the estimator. Therefore, in this paper, we proposed new biased estimator, called restricted modified unbiased ridge regression (RMUR) based on modified unbiased ridge regression (MURR) that suggested by Batah and Gory (2009). By some theorems and a simulation study, we show that, this new estimator has desirable properties as the MUR and it is better than the RLS. A numerical example from literature is used to illustrate the results.

1. Introduction

Consider the following linear regression model

$$Y = X\beta + \varepsilon, \quad (1)$$

where X is known (n×p) matrix with rank(X) = p , Y is (n×1) response vector , The error team ε is a n×1 vector of error with E(ε)=0 and var(ε)= $\sigma^2 I_n$ and β is a (p×1) unknown vector coefficient. Ordinary least square (OLS) estimator of β in model (1) is given by

$$\hat{\beta}_L = (X'X)^{-1}X'Y \quad (2)$$

When there is a linear relationship between independent variables, the problem of multicollinearity will be exist. In case of multicollinearity, the (OLS) estimator of regression coefficients may be statistically significant with wrong sign and large variance. Therefore the results are far from the actual values. To overcome this problem, the biased estimator has been used. One of these estimators is ordinary ridge regression ORR which proposed by Hoerl and Kennard (1970). Hoerl and Kennard derived the ORR estimator as the solution of the following problem; minimize $\beta^{*\prime}\beta^*$ subject to$(y - X\beta^*)'(y - X\beta^*) = c$. That means:

$$\beta^{*\prime}\beta^* + \frac{1}{k}[(y - X\beta^*)'(y - X\beta^*) - c] \quad (3)$$

Where $\frac{1}{k}$ is a Lagrangian multiplier and c is constant.The solution (3) obtained the (ORR) estimator as the following:

$$\hat{\beta}(k) = [I - k\left(X'X + kI_p\right)^{-1}\hat{\beta}_{LS}$$

$$= \left(X'X + kI_p\right)^{-1} X'Y \ , k > 0 \ . \tag{4}$$

Modified ridge estimator by Swindel (1976), the restricted ridge by Zhong and Yang (2007), modified new two-parameter by Lukman (2019), restricted and unrestricted by Ozkale (2007), Crouse et al. (1995) proposed the unbiased ridge regression (URR) estimator as the following:

$$\hat{\beta}(k,J) = \left(X'X + kI_p\right)^{-1}(X'Y + kJ) \ , k \geq 0 \tag{5}$$

where J is a random vector with $J \sim N\left(\beta, \frac{\sigma^2}{k} I_p\right)$ for $k > 0$.To improve the performance of the estimators by using biased estimation technique, Batah and Gore (2009) proposed modified unbiased ridge regression (MURR) as:

$$\begin{aligned} \hat{\beta}_J(k) &= \left[I - k\left(X'X + kI_p\right)^{-1}\right] \hat{\beta}(k,J) \\ &= \left[I - k\left(X'X + kI_p\right)^{-1}\right] \left(X'X + kI_p\right)^{-1}(X'Y + kJ) \end{aligned} \tag{6}$$

Although the (MURR) estimator is a good estimator in dealing with a problem of multicollinearity, as it is considered one of best biased estimators in dealing with this problem, but it also has negative characteristic and this characteristic arises from its dependence on the value of k. As $\rightarrow \infty$, $\hat{\beta}_J(k) \rightarrow 0$ a stable, but biased estimator of β. As $k \rightarrow 0$, $\hat{\beta}_J(k) \rightarrow \hat{\beta}_{RLS}$, an unbiased unstable estimator of β where $\widehat{\beta}_{RLS}$ still dealing with the matrix $X'X$ which is responsible for multicollinearity. That is $\hat{\beta}_J(k)$ trace curve path the parameter space from $\hat{\beta}_J(k)$ to zero, so the distance between $\hat{\beta}_J(k)$ and $\hat{\beta}_{RLS}$ decreases when k increases from 0. Therefore, we propose new biased estimator to improve the efficiency of estimation which we called restricted modified unbiased ridge regression (RMUR).

In section 2, we study the properties of new estimator. In section 3, we study the performance of the new estimator compared with some other estimators by using the simulation technique. Section 4 contains numerical example to illustrate the results. Finally, the conclusions with some remarks are given in section 5.

2. Proposed Estimator and its properties

To overcome the problem of multicollinearity we can also use prior information that can be considered as a linear restriction which is given by:

$$R\beta = r \ , \tag{7}$$

where R is an $(m \times p)$ known matrix with p rank $m > p$ and r is an $(m \times 1)$ vector.
The idea is that, we try to find an estimator of β that is closest to $\hat{\beta}_J(k)$ by taking a point that is closest to $\hat{\beta}_J(k)$ with same residual of sum square when the restrictions of β given by (6) are available. Thus, we derive a new estimator as the solution of the minimization problem for the function defined by

$$\Phi = \left(\beta - \hat{\beta}_J(k)\right)' \left(\beta - \hat{\beta}_J(k)\right) + \frac{1}{k}[(y - X\beta)'(y - X\beta) - c] - 2\lambda'(R\beta - r)$$

where $\frac{1}{k}$ is a Lagrangian multiplier, λ is a vector on Lagrangian multipliers and c is a constant. We differentiate the Φ with respect β and λ respectively, and we obtain the following equations.

$$\left(\beta^* - \hat{\beta}_J(k)\right) + \frac{1}{k}(X'X\beta^* - X'y) - R'\lambda = 0 \tag{8}$$

$$R\beta^* - r = 0 \tag{9}$$

From (7)

$$\beta^* = (X'X + k)^{-1}\left(X'y + k\hat{\beta}_J(k)\right) + (X'X + k)^{-1}R'k\lambda \tag{10}$$

If we premultiply (9) by R and inserting in (8), we obtain the solution of normal equations

$$\hat{\beta}_r^*(k) = \hat{\beta}_J(k) + S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\left(r - R\hat{\beta}_J(k)\right), \tag{11}$$

where $S_k^{-1} = (X'X + kI)^{-1}$.

Now, we need to show that $\hat{\beta}_r^*(k)$ satisfy the restrictions given by (6). Thus

$$R\,\hat{\beta}_r^*(k) = R[\hat{\beta}_j(k) + S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\left(r - R\hat{\beta}_j(k)\right)]$$
$$R\hat{\beta}_r^*(k) = R\hat{\beta}_j(k) + r - R\hat{\beta}_j(k)$$
$$= r$$

We can rewrite $\hat{\beta}_r^*(k)$ as follows:

Let $\beta_1 = R'(RR')^{-1}r$ and satisfy the restriction in (7), therefore, we have

$$\hat{\beta}_r^*(k) = \hat{\beta}_J(k) + S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\left(r - R\hat{\beta}_J(k)\right)$$
$$= S_k^{-1}S_k\hat{\beta}_J(k) + S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\left(r - RS_k^{-1}S_k\hat{\beta}_J(k)\right)$$
$$= S_k^{-1}S_k\hat{\beta}_J(k) + \left[S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\right]r - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}S_k\hat{\beta}_J(k)$$
$$= S_k^{-1}S_k\hat{\beta}_J(k) - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}S_k\hat{\beta}_J(k) + \left[S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\right]r$$
$$= \left(S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right)S_k\hat{\beta}_J(k) + \left[S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\right]r$$
$$= N_kS_k\hat{\beta}_J(k) + \left[S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\right]R\beta_1$$
$$= N_kS_k\hat{\beta}_J(k) + \left[S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}\right]R\beta_1 - S_k^{-1}S_k\beta_1 + \beta_1$$
$$= N_kS_k\hat{\beta}_J(k) - [S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}]S_k\beta_1 + \beta_1$$
$$= N_kS_k\hat{\beta}_j(k) - N_kS_k\beta_1 + \beta_1$$

$$\hat{\beta}_r^*(k) = N_kS_k\left(\hat{\beta}_J(k) - \beta_1\right) + \beta_1 \tag{12}$$

where $N_k = (S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}$

2.1 Matrix Mean Square Error (MMSE)

The bias and variance of an estimator are measured simultaneously by the mean square error matrix (MSE)

$$MSE(\beta^*) = var(\beta^*) + Biase(\beta^*)(Biase(\beta^*))'$$

For this purpose,

$$MSE(\hat{\beta}_J(k) = \sigma^2 WS^{-1}W' + k^2 S_k^{-1}\beta\beta' S_k^{-1}, \quad (13)$$

$$MES\left(\hat{\beta}_{RLS}\right) = \sigma^2 N_0 S^{-1} N_{0,} \quad (14)$$

$$MSE(\hat{\beta}_R(k) = \sigma^2 N_k S N_k' + k^2 N_k \beta\beta' N_k', \quad (15)$$

where $W = \left(I - kS_k^{-1}\right) = SS_k^{-1}$, $N_0 = N_k$ when $k = 0$ and $S = (X'X)$.

The expected value of RMUR is given by:

$$E(\hat{\beta}_r^*(k)) = E\left(N_k S_k\left(\hat{\beta}_j(k) - \beta_1\right) + \beta_1\right)$$

Since $E(\hat{\beta}_J(k)) = (I - kS_k^{-1})\beta$, so

$$E(\hat{\beta}_r^*(k)) = N_k S_k\left(\left(I - kS_k^{-1}\right)\beta - \beta_1\right) + \beta_1$$
$$= N_k S_k(\beta - \beta_1) + \beta_1 - kN_k\beta$$

Since $R\beta = r$, from $Eq(7)$ $R\beta_1 = r$. So, we get that $N_k S_k(\beta - \beta_1) = \beta - \beta_1$

Therefore,

$$E(\hat{\beta}_r^*(k)) = \beta - kN_k\beta = (I - kN_k)\beta \quad (16)$$

The variance, the bias and MMSE of RMUR are given as follows:

$$Var(\hat{\beta}_r^*(k) = E[(\hat{\beta}_r^*(k) - E\left(\hat{\beta}_r^*(k)\right)(\hat{\beta}_r^*(k) - E\left(\hat{\beta}_r^*(k)\right)'$$
$$= \sigma^2 N_k S_k W S_k^{-1} S_K' W' N_k', \quad (17)$$

where $w = \left(I - kS_k^{-1}\right) = SS_k^{-1}$.

$$\text{bias}(\hat{\beta}_r^*(k) = E\left(\hat{\beta}_r^*(k)\right) - \beta$$
$$= \beta - kN_k\beta - \beta =$$
$$-kN_k\beta \quad (18)$$

So that,

$$\text{MMSE}(\hat{\beta}_r^*(k)) = Var(\hat{\beta}_r^*(k)) + \left[bias\hat{\beta}_r^*(k)\right][bias\hat{\beta}_r^*(k)]'$$
$$= \sigma^2 N_k S_k W S_k^{-1} S_k' W' N_k' + k^2 N_k \beta\beta' N_k'. \quad (19)$$

The scalar mean square error of is defined as follows:

$$mse(\hat{\beta}_r^*(k)) = \sigma^2 tr\left(N_k S S S_k^{-1} N_k\right) + k^2 tr(N_k\beta\beta' N_k),$$

where tr denotes trace and $N_k = (S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1})$. It is will known that a linear regression model can be transformed to conical from by orthogonal transformation let T be an orthogonal matrix such that;

$$T'X'X = \Lambda \quad (20)$$

Where Λ is a $p \times p$ diagonal matrix elements $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_p$ are the eigenvalues

So, we can state the following theorem

Theorem 2.1**:** The scalar mean square error of $\hat{\beta}_r^*(k)$ is given by**:**

$$\text{mse}(\hat{\beta}_r^*(k)) = \sigma^2 \sum_{\text{i}=1}^{\text{p}} \frac{\lambda\text{i}^2(\lambda\text{i} + \text{k} - r_{ii}^*)^2}{(\lambda\text{i} + \text{k})^5} + \text{k}^2 \sum_{\text{i}=1}^{\text{p}} \frac{\propto_{\text{i}}^2 (\lambda\text{i} + \text{k} - r_{ii}^*)^2}{(\lambda\text{i} + \text{k})^4} \quad (21)$$

Proof:

$$N_k S S S_k^{-1} N_k = \left(S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right) S S S_k^{-1}\left(S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right)$$
$$= \left(S_k^{-1} S S S_k^{-2}\right) - (S_k^{-1} S S S_k^{-2} R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1} S S S_k^{-2}$$
$$+ S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1} S S S_k^{-2} R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1} \quad (22)$$

We have $S_k^{-1} = T(\Lambda + k)^{-1}T'$

$$tr\left(S_k^{-1}SSS_k^{-2}\right) = tr[(T(\Lambda+k)^{-1}T'T\Lambda T'T\Lambda T'(T(\Lambda+k)^{-2}T'] = tr[(T(\Lambda+k)^{-3}T'\,T\Lambda T'T\Lambda T']$$
$$= \sum_{i=1}^{p} \frac{\lambda_i^2}{(\lambda_i+k)^3}\,. \tag{23}$$

$$tr\left(S_k^{-1}SSS_k^{-2}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right) = tr[(T(\Lambda+k)^{-1}T'T\Lambda T'T\Lambda T'(T(\Lambda+k)^{-2}T'r_{ii}^{*}T(\Lambda+k)^{-1}T'\,]$$
$$= \sum_{i=1}^{p} \frac{\lambda_i^2 r_{ii}^{*}}{(\lambda_i+k)^4}. \tag{24}$$

$$R^{*} = TR'\left(RS_k^{-1}R'\right)RT'.\,The\ diag(R^{*}) = r_{ii}^{*}$$
$$tr\left(S_k^{-1}R'\left(RS_k^{-1}R\right)^{-1}RS_k^{-1}SSS_k^{-2}\right) = tr[T(\Lambda+k)^{-1}T'R^{*}T(\Lambda+k)^{-1}T'T\Lambda T'T\Lambda T'T(\Lambda+k)^{-2}T'\,]$$
$$= \sum_{i=1}^{p} \frac{\lambda_i^2 r_{ii}^{*}}{(\lambda_i+k)^4}\,. \tag{25}$$

$$tr\left(S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}SSS_k^{-2}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right) = tr[T(\Lambda+k)^{-1}T'R^{*}T(\Lambda+k)^{-1}T'T\Lambda T'T\Lambda T'T(\Lambda+k)^{-2}T'R^{*}T(\Lambda+k)^{-1}T']$$
$$= \sum_{i=1}^{p} \frac{\lambda_i^2 r_{ii}^{*2}}{(\lambda_i+k)^5}\,. \tag{26}$$

From (23), (24), (25) and (26), we get the following result.

$$tr\left(N_kSSS_k^{-1}N_k\right) = \left[\sum_{i=1}^{p} \frac{\lambda_i^2}{(\lambda_i+k)^3} - 2\sum_{i=1}^{p} \frac{\lambda_i^2 r_{ii}^{*2}}{(\lambda_i+k)^4} + \sum_{i=1}^{p} \frac{\lambda_i^2 r_{ii}^{*2}}{(\lambda_i+k)^5}\right]$$
$$= \sum_{i=i}^{p} \frac{\lambda_i^2(\lambda_i+k-r_{ii}^{*})^2}{(\lambda_i+k)^5}\,. \tag{27}$$

Also,

$$tr\left(N_k^2\right) = \left(S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right)\left(S_k^{-1} - S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right)$$
$$= S_k^{-2} - S_k^{-2}R'\left(RS_k^{-1}R'\right)RS_k^{-1} - S_k^{-1}R'(RS_kR')RS_k^{-2}$$
$$+S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-2}R'\left(RS_k^{-1}R'\right)^{-1} \tag{28}$$

$$tr\left(S_k^{-2}\right) = tr(T(\Lambda+k)^2T') = \sum_{i=1}^{p} \frac{1}{(\lambda_i+k)^2} \tag{29}$$

$$tr\left(S_k^{-2}R'\left(RS_k^{-1}R'\right)RS_k^{-1}\right) = tr[T(\Lambda+k)^{-2}T'R^{*}T(\Lambda+k)^{-1}T'] = \sum_{i=1}^{p} \frac{r_{ii}^{*}}{(\lambda_i+k)^3}. \tag{30}$$

Similar to (30), we get:

$$tr\left(S_k^{-1}R'(RS_kR')RS_k^{-2}\right) = \sum_{i=1}^{p} \frac{r_{ii}^{*}}{(\lambda_i+k)^3}\,. \tag{31}$$

$$tr\left(S_k^{-1}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-2}R'\left(RS_k^{-1}R'\right)^{-1}RS_k^{-1}\right)$$

$$= \sum_{i=1}^{p} \frac{r_{ii}^{*2}}{(\lambda_i + k)^4} \quad . \tag{32}$$

From (28) to (32), we get

$$tr(N_k^2) = \sum_{i=1}^{p} \left(\frac{1}{(\lambda_i + k)^2} - \frac{2r_{ii}^*}{(\lambda_i + k)^3} + \frac{r_{ii}^{*2}}{(\lambda_i + k)^4} \right)$$

$$= \sum_{i=1}^{p} \frac{(\lambda_i + k - r_{ii}^*)^2}{(\lambda_i + k)^4} \, . \tag{33}$$

Therefore,

$$tr(\propto' N_k^2 \propto) = \sum_{i=1}^{p} \frac{\propto_i^2 (\lambda_i + k - r_{ii}^*)^2}{(\lambda_i + k)^4} \, . \tag{34}$$

Where $\propto = T'\beta = (\propto_1 \dots\dots\dots \propto_p)$. Finally, we have

$mse(\hat{\beta}_r^*(k)) = \sigma^2 \sum_{i=1}^{p} \frac{\lambda i^2 (\lambda i + k - r_{ii}^*)^2}{(\lambda i + k)^5} + k^2 \sum_{i=1}^{p} \frac{\propto_i^2 (\lambda i + k - r_{ii}^*)^2}{(\lambda i + k)^4}$.

The proof is completed.

3. Simulation Study

The purpose of this section is to make a comparison among the different biased estimators in order to identify good estimator among them. Therefore, we conduct a simulation study by using the Matlab program. This simulation is created depending on factors that affect the properties of the estimator's duo to the degree of the collinearity among several explanatory variables. Kibria (2003) was followed to generate the explanatory variables by using the equation.

$$x_{ij} = (1 - \Upsilon^2)^{\frac{1}{2}} z_{ij} + \Upsilon z_{ip} \, , \qquad i = 1 \dots\dots n \quad , j = 1 \dots\dots p \tag{35}$$

where the z_{ij} independent standard normal pseudo-random numbers and Υ represents the correlation between any two variables. These variables are standardized so that $X'X$ is being in correlation form. The response variable y is considered by:

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \cdots \dots\dots\dots + \beta_p x_{ip} + e_i, \qquad i = 1,2, \dots\dots, n \tag{36}$$

where e_i is i.i.d. N(0, σ^2). Therefore, zero intercept for (36) will be assumed. Also the number of explanatory variables $p = 4$, while the values of σ are choose as (1, 4, 9,). The correlation Υ will choose as (0.90, 0.95,0.99) and sample size n as (25, 50 ,100,).The coefficients $\beta_1, \beta_2, \dots, \beta_p$ are selected as the eigenvectors corresponding to the largest eigenvalue of the matrix $X'X$ subject to constraint $\beta'\beta$ = 1. Thus, for all n , σ , λ , p , β and Υ, sets of Xs are created. The experiment was replicated 5000 times by creating new error terms. Estimated mean square error (EMSE) is calculated as follows:

$EMSE(\beta^*) = \frac{1}{5000} \sum_{i=1}^{5000} (\beta^* - \beta)'(\beta^* - \beta)$,

where β^* would be any estimators (RLS, MURR, RRR or RMUR).

3.1 The discussion of simulation results

In this article, we present the results of the Monte Carlo experiment regarding of the properties of the different methods that used to choose the ridge parameter k. The simulation results are presented from Table 1 to Table 7 and we discuss the results in all cases.

Table1 and Table 7 show the performance of the RMUR estimator compared to some other estimators as the following:

1.The RMUR estimator is the best, because the RMUR estimator has lowest MSE compared with other estimators for all different sample size n in all correlation coefficient values and σ. However, in some cases the MURR estimator is close or similar to the RMUR estimator from these cases.

2.In case ($n = 25, \ \sigma = 1, \ \Upsilon = .90$) and ($n = 50, \ \sigma = 1, \Upsilon = .90$), the MUR estimator is close or similar the RMUR estimator in this cases.

4.**Numerical example**

In this study, the performance of the proposed estimator using a real life data is illustrated. We consider the data about the total national product, which is cited by Akdeniz (2003) for comparison of the estimators that given in this study. This data shows the relationship between the dependent variable Y and the percentage that is the united states spent on four independent variables X_1, X_2, X_3 and X_4 representing the percentage spent by Farance, West Germany, Japan, and Soviet Union respectively.
The goal is to compare the scalar mean square error mse of the RLS, RRR, MURR and RMUR. The mse of the MURR, RLS, RRR and RMUR are given in Eq.(3), Eq.(14), Eq.(15) and Eq.(19) respectively, which given in Table 8.

Table 1. The scalar mean square error for different estimators and different estimated ridge parameter

k	OLS	RLS	RRR	$MURR$	$RMUR$
0.0161	602.4197	135.7475	96.4878	159.9901	83.1722
0.0243	602.4197	135.7475	83.0983	110.1283	67.6833
0.050	602.4197	135.7475	56.1576	54.1576	40.0858
0.020	602.4197	135.7475	89.7099	131.9846	75.1888
0.50	602.4197	135.7475	7.0013	5.9080	3.7911
0.10	602.4197	135.7475	32.7403	26.7126	20.2068
0.15	602.4197	135.7475	22.5322	17.7867	13.0448

For the linear restrictions (6), the values *R* and *r* are, respectively, given as follows Najarian (2013)
$R = [1\ 1\ 1\ 1\ ;0\ 1\ 3\ 1\ ], \quad r = [1.2170\ \ 1.0904]$
In Table 8, we can observe that, the RMUR estimator has lowest *mse* for all different estimated ridge parameter. Therefore, the performance the RMUR estimator is better than other estimators and this is clear in the Figures 1,2 and 3.

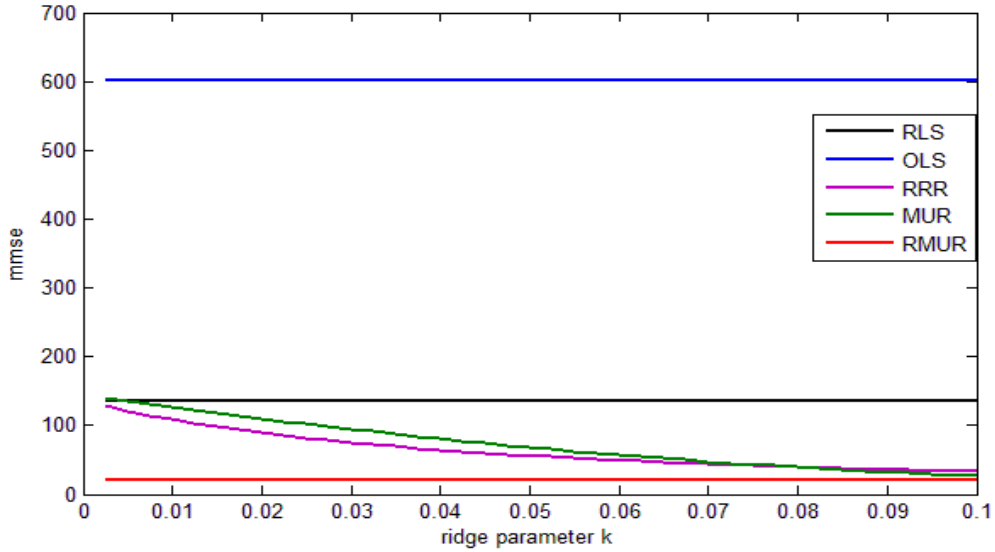

Figure 1. Estimated mse of the proposed estimator compared for different estimators and different estimated ridge parameter k.

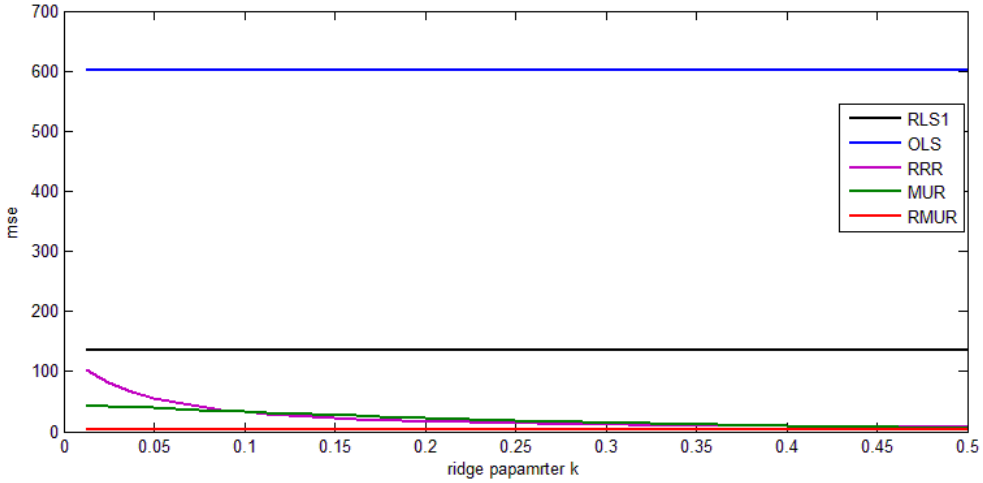

Figure 2. Estimated mse of the proposed estimator compared for different estimators and different estimated ridge parameter k.

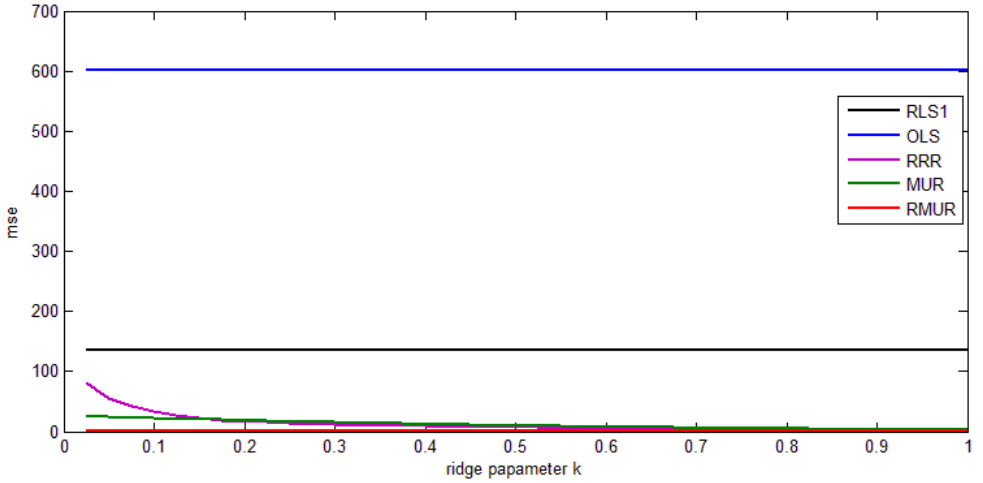

Figure 3. Estimated mse of the proposed estimator compared for different estimators and different estimated ridge parameter k.

5. Conclusions

The simulation study in section 3 shows that, the RMOR estimator is better than of the other estimators for all values n , σ and Υ. Also, the RMUR estimator has good properties compared with other estimators. The RMUR estimator is more efficient where it has lowest mean square error compared to others, and with respect to the real data that used in the present study.

Truncated Exponential Topp Leone Exponential Distribution: Properties and Applications

Truncated Exponential Topp Leone Exponential Distribution: Properties and Applications

Nadia Hashim Al-Noor and Omar Ali Hilal

Mathematics Department, College of Science, Mustansiriyah University, Baghdad, Iraq

E-mail: nadialnoor@uomustansiriyah.edu.iq

Abstract. A new flexible compound distribution with three parameters named Truncated Exponential Topp Leone Exponential (TETLE) is introduced as a sub-model of a new generator family named Truncated Exponential Topp Leone-G. Several keys of its statistical properties, order statistics, entropies, reliability analysis, and reliability stress strength model are presented. The maximum likelihood estimation method is implemented to estimate the unknown parameters. Moreover, to assess the flexibility and usefulness, the TETLE distribution applied upon simulation and two real-life data set. The consistent and flexible performance of the maximum likelihood estimates is clearly appeared by the simulation results and the results of the real application clearly shown that the proposed distribution has superior output relative to other considered distributions for all information criteria.

1. Introduction

Lifetime data plays a significant role in an extensive variety of applications, such as public health, management, engineering, medicine, and biological sciences. Statistical distributions are used to model these data in order to examine its essential characteristics. Appropriate distribution can provide valuable information that leads to putting conclusions and decisions. When more flexible distributions are needed, many researchers are about to use the new one with more generalization. One of the supremely important distributions is the exponential distribution. It has been applied to match life data in a number of fields. However, some of these applications are restricted in part, and this restriction is certainly an opportunity for researchers to create new generalizations and to make a variety of improvements to this distribution in order to increase its flexibility. In this paper, based on the well-known exponential distribution, a new family of probability distributions is introduced through the works of Topp and Leone [1] and Eugene et al. [2].

Topp and Leone (1955) [1] developed a new distribution of empirical data with J-shaped histograms. The Topp Leone (TL) distribution had not received much attention until it discovered by Nadarajah and Kotz (2003) [3] when they studied some of its properties, moments, central moments, and characteristic function. Furthermore, among the important work of analyzing lifetime data that revealed a significant influence of the TL distribution are, Ghitany et al. (2005) [4] provided TL reliability measures, Kotz and Seier (2007) [5] offered a discussion on TL kurtosis, Vicaria et al. (2008) [6] introduced two-sided generalized TL distributions, Al-Zahrani (2012) [7] derived TL goodness of fit tests, and Sangsanit and Bodhisuwan (2016) [8] proposed the TL generated (TL-G) family of distributions.

The cumulative distribution function (cdf) and probability density function (pdf) of the TL-G family, that due to Sangsanit and Bodhisuwan [8], with one shape parameter α beside the cdf and pdf of an arbitrary (parent or baseline) distribution, say $G(x)$ and $g(x)$, are

$$M(x)_{TL} = \big(G(x)\big)^{\alpha}\big(2 - G(x)\big)^{\alpha}\ ;\ \alpha > 0 \tag{1}$$

$$m(x)_{TL} = 2\alpha\ g(x)\big(G(x)\big)^{\alpha-1}\big(1 - G(x)\big)\big(2 - G(x)\big)^{\alpha-1} \tag{2}$$

Eugene et al. [2] proposed a new family based on beta distribution with the cdf and pdf as below

$$F(x)_T = \frac{1}{\beta(a,b)}\int_0^{M(x)} t^{a-1}\ (1-t)^{b-1}\,dt\ ;\ 0 < t < 1 \text{ and } 0 < a, b < \infty \tag{3}$$

$$f(x)_T = \frac{1}{\beta(a,b)}\,(M(x))^{a-1}\,(1 - M(x))^{b-1}\,m(x) \tag{4}$$

where $M(x)$ and $m(x)$ are the cdf and pdf of any distribution and $\beta(a,b)$ represent Beta function. Then Eugene et al. derived some properties of the beta normal distribution that defined by taking $M(x)$ to be the cdf of the normal distribution (see [2][9]).

Taking motivation from the works above, a new family named truncated exponential Topp Leone– G has been proposed (for more details about TL distribution and truncated distribution see [2] and [10]). The rest of this paper is organized as follows: the truncated exponential Topp Leone – G family is introduced in Section 2 with several general useful expressions. In Section 3, attention is given the truncated exponential Topp Leone exponential as a sub-model of the new family. In Sections 4, and 5 various properties besides order statistics, entropies, reliability measures, and reliability stress strength model are presented. The maximum likelihood estimators of the parameters are presented in Section 6. In Section 7, numerical illustrations are implemented in order to illustrate the behavior of the new distribution. Finally, in Section 8, conclusions are listed.

2. Truncated Exponential Topp Leone-G family

Consider $H(x)_{TE}$ and $h(x)_{TE}$ are the cdf and pdf of the truncated exponential distribution with scale parameter λ, i.e.

$$H(x)_{TE} = \frac{1 - e^{-\lambda x}}{1 - e^{-\lambda}}\ ;\ 0 < x < 1\ , \lambda > 0 \tag{5}$$

$$h(x)_{TE} = \frac{\lambda e^{-\lambda x}}{1 - e^{-\lambda}} \tag{6}$$

By composing the two continuous cdfs (H, M), the cdf $F(x) = H\big(M(x)\big)$ and corresponding pdf $f(x) = \frac{\partial}{\partial x}F(x)$ will be

$$F(x) = \int_0^{M(x)} \frac{\lambda e^{-\lambda v}}{1 - e^{-\lambda}}\ dv = \frac{1 - e^{-\lambda M(x)}}{1 - e^{-\lambda}} \tag{7}$$

$$f(x) = \frac{\lambda m(x)\ e^{-\lambda M(x)}}{1 - e^{-\lambda}} \tag{8}$$

Replacing $M(x)$ and $m(x)$ in (7) and (8) by (1) and (2), a new generator family of probability distributions named Truncated Exponential Topp Leone-G (TETL-G) can be proposed.

The cdf and pdf of the proposed family are

$$F(x)_{TETL-G} = \frac{1}{1-e^{-\lambda}}\left(1 - e^{-\lambda\left(G(x)\right)^{\alpha}\left(2-G(x)\right)^{\alpha}}\right) \tag{9}$$

$$f(x)_{TETL-G} = \frac{2\lambda\alpha}{1-e^{-\lambda}}\, g(x)\big(G(x)\big)^{\alpha-1}\big(1-G(x)\big)\big(2-G(x)\big)^{\alpha-1}\, e^{-\lambda\left(G(x)\right)^{\alpha}\left(2-G(x)\right)^{\alpha}} \tag{10}$$

Also, the useful expansion formula of the above pdf can be got by using the expansion formulas below:

$$e^{-z} = \Sigma_{k=0}^{\infty} \frac{(-1)^k}{k!} z^k \tag{E1}$$

$$(1-z)^a = \sum_{m=0}^{\infty} \frac{(-1)^m}{m!} \frac{\Gamma(a+1)}{\Gamma(a-m+1)}\, z^m \text{ with } |z|<1 \text{ and } a>0 \tag{E2}$$

$$(1-z)^{-a} = \sum_{m=0}^{\infty} \frac{\Gamma(a+m)}{m!\,\Gamma(a)}\, z^m \text{ with } |z|<1 \text{ and } a>0 \tag{E3}$$

Now, based on the above expansion formulas, we get

$$e^{-\lambda\left(G(x)\right)^{\alpha}\left(2-G(x)\right)^{\alpha}} = \sum_{k=0}^{\infty} \frac{(-1)^k}{k!}\, \lambda^k \big(G(x)\big)^{k\alpha}\big(2-G(x)\big)^{k\alpha}, \text{ and}$$

$$\big(2-G(x)\big)^{\alpha(k+1)-1} = \begin{cases} \sum_{m=0}^{\infty} \frac{(-1)^m}{m!} 2^{\alpha(k+1)-m-1} \frac{\Gamma(\alpha(k+1))}{\Gamma(\alpha(k+1)-m)} \big(G(x)\big)^m ; & \alpha(k+1)-1>0 \\ \sum_{m=0}^{\infty} \frac{\Gamma(\alpha(k+1)+m-1)}{m!\,\Gamma(\alpha(k+1)-1)} 2^{\alpha(k+1)-m-1} \big(G(x)\big)^m ; & \alpha(k+1)-1<0 \end{cases}$$

Then expansion of (10) will be

$$f^E(x)_{TETL-G} = W g(x)\big(G(x)\big)^{m+\alpha(k+1)-1}\big(1-G(x)\big) \tag{11}$$

where

$$W = \begin{cases} \frac{1}{1-e^{-\lambda}} \sum_{k,m=0}^{\infty} \frac{(-1)^{k+m}}{k!\,m!} \frac{\Gamma(\alpha(k+1))}{\Gamma(\alpha(k+1)-m)} \alpha\lambda^{k+1}\, 2^{\alpha(k+1)-m} & ; \ \alpha(k+1)-1>0 \\ \frac{1}{1-e^{-\lambda}} \sum_{k,m=0}^{\infty} \frac{(-1)^k}{k!\,m!} \frac{\Gamma(\alpha(k+1)+m-1)}{\Gamma(\alpha(k+1)-1)} \alpha\lambda^{k+1}\, 2^{\alpha(k+1)-m} & ; \ \alpha(k+1)-1<0 \end{cases} \tag{12}$$

3. Truncated Exponential Topp Leone Exponential distribution

Consider $G(x)$ and $g(x)$ in (9), (10), and (11) be the cdf and pdf of the exponential distribution with positive scale parameter θ, then a new distribution called Truncated Exponential Topp Leone Exponential (TETLE) distribution can be proposed as a member of TETL-G family with the cdf, pdf and expanded pdf given respectively by

$$F(x)_{TETLE} = \frac{1}{1-e^{-\lambda}}\left(1 - e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}\right) \tag{13}$$

$$f(x)_{TETLE} = \frac{2\lambda\alpha\theta}{1-e^{-\lambda}}\, e^{-2\theta x} e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}} \left(1-e^{-2\theta x}\right)^{\alpha-1} \tag{14}$$

and

$$f^{E}(x)_{TETLE} = W\theta e^{-2\theta x}\left(1-e^{-\theta x}\right)^{m+\alpha(k+1)-1} \tag{15}$$

with W as in (12).

The plots of the cdf and pdf of the $TETLE$ distribution for particular parameter values are presented in Figures 1 and 2. It is noted that this new distribution is very flexible to model positive data.

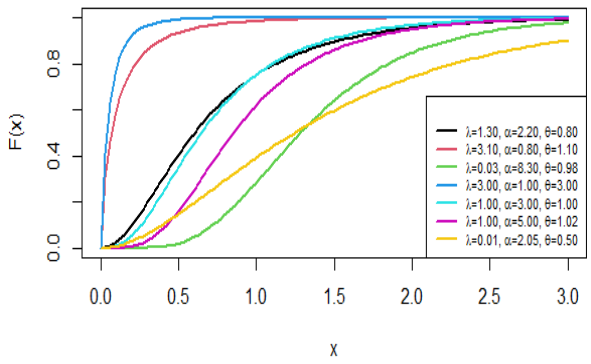

Figure 1. The cdf plot of $TETLE$ distribution for particular parameter values

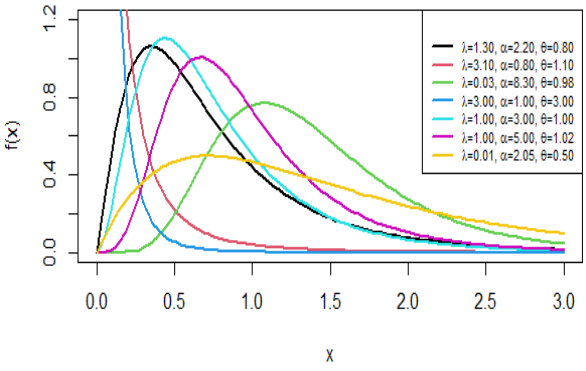

Figure 2. The pdf plot of $TETLE$ distribution for particular parameter values

4. Statistical properties and order statistics of TETLE distribution

The r^{th} moment can be found regards to (15) as follows

$$E(X^r)_{TETLE} = \int_0^{\infty} x^r f^{E}(x)_{TETLE}\, dx = W\int_0^{\infty} x^r \theta e^{-2\theta x}\left(1-e^{-\theta x}\right)^{m+\alpha(k+1)-1} dx$$

Now, based on $(E2)$ and $(E3)$, we get

$$\left(1-e^{-\theta x}\right)^{m+\alpha(k+1)-1} = \begin{cases} \sum_{t=0}^{\infty} \frac{(-1)^t}{t!}\frac{\Gamma(m+\alpha(k+1))}{\Gamma(m+\alpha(k+1)-t)} e^{-\theta t x} & ;\ m+\alpha(k+1)-1>0 \\ \sum_{t=0}^{\infty} \frac{\Gamma(m+\alpha(k+1)+t-1)}{t!\,\Gamma(m+\alpha(k+1)-1)} e^{-\theta t x} & ;\ m+\alpha(k+1)-1<0 \end{cases}$$

Now $E(X^r)_{TETLE}$ with $m+\alpha(k+1)-1>0$ will be

$$E(X^r)_{TETLE} = W\,\Sigma_{t=0}^{\infty}\frac{(-1)^t}{t!}\frac{\Gamma\left(m+\alpha(k+1)\right)}{\Gamma(m+\alpha(k+1)-t)}\int_0^{\infty} x^r\theta\, e^{-\theta(t+2)x}\, dx$$

$$= W\,\Sigma_{t=0}^{\infty}\frac{(-1)^t}{t!}\frac{\Gamma\left(m+\alpha(k+1)\right)}{\Gamma(m+\alpha(k+1)-t)}\frac{1}{(t+2)}\int_0^{\infty} x^r\theta(t+2)\, e^{-\theta(t+2)x}\, dx$$

Since $\int_0^{\infty} x^r\theta(t+2)\, e^{-\theta(t+2)x}\, dx$ represent the r^{th} moment of exponential distribution with parameters $\theta(t+2)$, thus $E(X^r)_{TETLE}$ becomes

$$E(X^r)_{TETLE} = W\,\Sigma_{t=0}^{\infty}\frac{(-1)^t}{t!}\frac{\Gamma\big(m+\alpha(k+1)\big)}{\Gamma(m+\alpha(k+1)-t)}\frac{r!}{(t+2)\big(\theta(t+2)\big)^r}$$

and the $E(X^r)_{TETLE}$ with $m+\alpha(k+1)-1<0$ becomes

$$\begin{aligned}E(X^r)_{TETLE} &= W\,\Sigma_{t=0}^{\infty}\frac{\Gamma(m+\alpha(k+1)+t-1)}{t!\;\Gamma(m+\alpha(k+1)-1)}\int_0^{\infty}x^r\theta\,e^{-\theta(t+2)x}\,dx\\ &= W\,\Sigma_{t=0}^{\infty}\frac{\Gamma(m+\alpha(k+1)+t-1)}{t!\;\Gamma(m+\alpha(k+1)-1)}\frac{1}{(t+2)}\int_0^{\infty}x^r\theta(t+2)\,e^{-\theta(t+2)x}\,dx\\ &= W\,\Sigma_{t=0}^{\infty}\frac{\Gamma(m+\alpha(k+1)+t-1)}{t!\;\Gamma(m+\alpha(k+1)-1)}\frac{r!}{(t+2)\big(\theta(t+2)\big)^r}\end{aligned}$$

Thus, the r^{th} moment of $TETLE$ distribution is

$$E(X^r)_{TETLE} = \begin{cases} W\,\Sigma_{t=0}^{\infty}\dfrac{(-1)^t}{t!}\dfrac{\Gamma\big(m+\alpha(k+1)\big)}{\Gamma(m+\alpha(k+1)-t)}\dfrac{r!}{\theta^r(t+2)^{r+1}} & ;\ m+\alpha(k+1)-1>0\\ W\,\Sigma_{t=0}^{\infty}\dfrac{\Gamma(m+\alpha(k+1)+t-1)}{t!\;\Gamma(m+\alpha(k+1)-1)}\dfrac{r!}{\theta^r(t+2)^{r+1}} & ;\ m+\alpha(k+1)-1<0\end{cases} \tag{16}$$

where W as in (12).

With $(r=1,2,3,4)$, another properties such as the mean $\big(E(X)\big)$, the variance $(E(X^2)-[E(X)]^2)$, the coefficient of skewness $\left(\frac{E(X^3)-3E(X)E(X^2)+2[E(X)]^3}{[var(X)]^{3/2}}\right)$, and the coefficient of kurtosis $\left(\frac{E(X^4)-4E(X)E(X^3)+6E(X^2)[E(X)]^2-3[E(X)]^4}{[var(X)]^2}\right)$ (see [11]) can be calculated.

The TETLE characteristic function can easily be found via $\varphi_X(t)_{TEMOW} = \sum_{r=0}^{\infty}\frac{(it)^r}{r!}E(X^r)_{TETLE}$ as

$$\varphi_X(t)_{TETLE} = \begin{cases} W\,\Sigma_{t,r=0}^{\infty}\dfrac{(-1)^t(it)^r}{t!\;r!}\dfrac{\Gamma\big(m+\alpha(k+1)\big)}{\Gamma(m+\alpha(k+1)-t)}\dfrac{r!}{\theta^r(t+2)^{r+1}} & ;\ m+\alpha(k+1)-1>0\\ W\,\Sigma_{t,r=0}^{\infty}\dfrac{(it)^r\,\Gamma(m+\alpha(k+1)+t-1)}{t!\;r!\,\Gamma(m+\alpha(k+1)-1)}\dfrac{r!}{\theta^r(t+2)^{r+1}} & ;\ m+\alpha(k+1)-1<0\end{cases} \tag{17}$$

By inverting the cdf in (13), The $TETLE$ quantile function can be achieved as

$$Q(q)_{TETLE} = \frac{-1}{2\theta}\ln\left(1-\left(\frac{-1}{\lambda}\ln\left(1-\,q\big(1-e^{-\lambda}\big)\right)\right)^{\frac{1}{\alpha}}\right) \tag{18}$$

By setting $q=\frac{1}{2}$, the median of $TETLE$ random variable can be gained as

$$median_{TETLE} = Q\left(\frac{1}{2}\right)_{TETLE} = \frac{-1}{2\theta}\ln\left(1-\left(\frac{-1}{\lambda}\ln\left(\frac{1}{2}\big(1+e^{-\lambda}\big)\right)\right)^{\frac{1}{\alpha}}\right) \tag{19}$$

A random variable of TETLE distribution can be generated by

$$x_{TETLE} = \frac{-1}{2\theta}\ln\left(1 - \left(\frac{-1}{\lambda}\ln\left(1 - U\left(1 - e^{-\lambda}\right)\right)\right)^{\frac{1}{\alpha}}\right) \tag{20}$$

where U follow the standard Uniform distribution.

Order statistics: Let $x_{1:n}, x_{2:n}, \dots, x_{n:n}$ the order statistics of a random sample $x_1, x_2, \dots, x_n$ of size n taken independently from a probability distribution. The standard formulas of the pdf and the joint pdf of order statistics are as follows (see [12])

$$f_{k:n}(x) = \frac{n!}{(k-1)!\,(n-k)!}\left(F(x)\right)^{k-1}\left(1 - F(x)\right)^{n-k} f(x) \;\; ; \; 0 \le x_{k:n} < \infty, k \le n$$

$$f_{j,k:n}(x,y) = \frac{n!}{(j-1)!\,(k-j-1)!\,(n-k)!}\left(F(x)\right)^{j-1}\left(F(y) - F(x)\right)^{k-j-1} \left(1 - F(y)\right)^{n-k} f(x)\, f(y) \;\; ; \; 1 \le j \le k\,, 0 \le x \le y < \infty$$

Based on (13) and (14), the pdf and the joint pdf of $TETLE$ order statistics will be

$$f_{k:n}(x)_{TETLE} = \frac{n!}{(k-1)!\,(n-k)!}\left(1 - e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}\right)^{k-1}\left(e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}} - e^{-\lambda}\right)^{n-k} \frac{2\lambda\alpha\theta}{\left(1-e^{-\lambda}\right)^{n}}\, e^{-2\theta x} e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}\left(1 - e^{-2\theta x}\right)^{\alpha-1}; \; 0 \le x_{k:n} < \infty, k \le n \tag{21}$$

$$f_{j,k:n}(x,y)_{TETLE} = \frac{n!}{(j-1)!\,(k-j-1)!\,(n-k)!}\frac{4\lambda^2\alpha^2\theta^2}{\left(1-e^{-\lambda}\right)^{n}}\left(1 - e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}\right)^{j-1} \left(e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}} - e^{-\lambda\left(1-e^{-2\theta y}\right)^{\alpha}}\right)^{k-j-1}\left(e^{-\lambda\left(1-e^{-2\theta y}\right)^{\alpha}} - e^{-\lambda}\right)^{n-k} e^{-2\theta(x+y)} e^{-\lambda\left(\left(1-e^{-2\theta x}\right)^{\alpha} + \left(1-e^{-2\theta y}\right)^{\alpha}\right)}\left(1 - e^{-2\theta x}\right)^{\alpha-1}\left(1 - e^{-2\theta y}\right)^{\alpha-1}; \; 1 \le j \le k\,, 0 \le x \le y < \infty \tag{22}$$

5. The entropies, reliability measures, and reliability stress strength of $TETLE$ distribution

Here the entropies (Shannon entropy, and Relative entropy), reliability measures, and reliability stress strength model of $TETLE$ distribution are obtained as follows:

Shannon entropy: The $TETLE$ Shannon entropy can be achieved from (14), as follows:

$Sh_{TETLE} = -\int_0^{\infty} \ln(f(x)_{TETLE})\, f(x)_{TETLE}\, dx$ with

$$\ln(f(x)_{TETLE}) = \ln\left(\frac{2\lambda\alpha\theta}{1 - e^{-\lambda}}\right) - 2\theta x - \lambda\left(1 - e^{-2\theta x}\right)^{\alpha} + (\alpha - 1)\ln\left(1 - e^{-2\theta x}\right)$$

Then

$$Sh_{TETLE} = \ln\left(\frac{1 - e^{-\lambda}}{2\lambda\alpha\theta}\right) + 2\theta E(X) + \lambda E\left(\left(1 - e^{-2\theta X}\right)^{\alpha}\right) - (\alpha - 1)\, E\left(\ln\left(1 - e^{-2\theta X}\right)\right) \tag{23}$$

where $E(X)$ as in (16) with $r = 1$, and

$$E\left(\left(1 - e^{-2\theta X}\right)^{\alpha}\right) = \int_0^{\infty}\left(1 - e^{-2\theta x}\right)^{\alpha} f(x)_{TETLE}\, dx$$

Recall $(E2)$ and $(E1)$, we get $\left(1-e^{-2\theta x}\right)^{\alpha}=\Sigma_{i,j=0}^{\infty}\frac{(-1)^{i+j}\,\Gamma(\alpha+1)}{i!\,j!\,\Gamma(\alpha-i+1)}(2\theta i)^{j}\,x^{j}$, then

$$E\left(\left(1-e^{-2\theta X}\right)^{\alpha}\right)=\Sigma_{i,j=0}^{\infty}\frac{(-1)^{i+j}\,\Gamma(\alpha+1)}{i!\,j!\,\Gamma(\alpha-i+1)}(2\theta i)^{j}\,E\left(X^{j}\right) \tag{24}$$

where $E\left(X^{j}\right)$ as in (16) with $r=j$.

Now for $E\left(\ln\left(1-e^{-2\theta X}\right)\right)=\int_{0}^{\infty}\ln\left(1-e^{-2\theta x}\right)f(x)_{TETLE}\,dx$, using the following expansion formula

$$\ln(1-z)=-\Sigma_{i=1}^{\infty}\frac{z^{i}}{i}\;;|z|<1 \tag{E4}$$

with using $(E1)$, we get $\ln\left(1-e^{-2\theta x}\right)=\Sigma_{k=1}^{\infty}\Sigma_{l=0}^{\infty}\frac{(-1)^{l+1}}{k\,l!}(2\theta k)^{l}\,x^{l}$, and then

$$E\left(\ln\left(1-e^{-2\theta X}\right)\right)=\Sigma_{k=1}^{\infty}\Sigma_{l=0}^{\infty}\frac{(-1)^{l+1}}{k\,l!}(2\theta k)^{l}\,E\left(X^{l}\right) \tag{25}$$

where $E\left(X^{l}\right)$ as in (16) with $r=l$.

Relative entropy: Consider $f(x)_{TETLE}$ and $f^{*}(x)_{TETLE}$ are the $TETLE$ pdf respectively, with parameters (λ,α,θ) and $(\lambda^{*},\alpha^{*},\theta^{*})$ then

$$\ln\frac{f(x)_{TETLE}}{f^{*}(x)_{TETLE}}=\ln\left(\frac{\lambda\alpha\theta\left(1-e^{-\lambda^{*}}\right)}{\lambda^{*}\alpha^{*}\theta^{*}(1-e^{-\lambda})}\right)-2(\theta-\theta^{*})x-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}+\lambda^{*}\left(1-e^{-2\theta^{*}x}\right)^{\alpha^{*}}$$
$$+(\alpha-1)\ln\left(1-e^{-2\theta x}\right)-(\alpha^{*}-1)\ln\left(1-e^{-2\theta^{*}x}\right)$$

The $TETLE$ relative entropy is given by

$$RE_{TETLE}=E\left(\ln\frac{f(x)_{TETLE}}{f^{*}(x)_{TETLE}}\right)=\ln\left(\frac{\lambda\alpha\theta\left(1-e^{-\lambda^{*}}\right)}{\lambda^{*}\alpha^{*}\theta^{*}(1-e^{-\lambda})}\right)-2(\theta-\theta^{*})E(X)$$
$$-\lambda E\left(\left(1-e^{-2\theta X}\right)^{\alpha}\right)+\lambda^{*}E\left(\left(1-e^{-2\theta^{*}X}\right)^{\alpha^{*}}\right)$$
$$+(\alpha-1)E\left(\ln\left(1-e^{-2\theta X}\right)\right)-(\alpha^{*}-1)E\left(\ln\left(1-e^{-2\theta^{*}X}\right)\right) \tag{26}$$

with $E(X)$ as in (16) with $r=1$ and other expectations with specified parameters as in (24), and (25).

Reliability measures: Based on (13) and (14), the $TETLE$ functions of reliability, hazard, cumulative hazard, and reverse hazard can easily be found respectively as (see [13])

$$\tau_{1}(x)_{TETLE}=1-F(x)_{TETLE}=\frac{1}{1-e^{-\lambda}}\left(e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}-e^{-\lambda}\right) \tag{27}$$

$$\tau_{2}(x)_{TETLE}=\frac{f(x)_{TETLE}}{R(x)_{TETLE}}=\frac{2\lambda\alpha\theta\,e^{-2\theta x}e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}\left(1-e^{-2\theta x}\right)^{\alpha-1}}{e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}-e^{-\lambda}} \tag{28}$$

$$\tau_{3}(x)_{TETLE}=-\ln(R(x)_{TETLE})=-\ln\left(1-\frac{1}{1-e^{-\lambda}}\left(1-e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}\right)\right) \tag{29}$$

$$\tau_4(x)_{TETLE} = \frac{f(x)_{TETLE}}{F(x)_{TETLE}} = \frac{2\lambda\alpha\theta\, e^{-2\theta x} e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}} \left(1-e^{-2\theta x}\right)^{\alpha-1}}{1-e^{-\lambda\left(1-e^{-2\theta x}\right)^{\alpha}}} \quad (30)$$

Reliability stress strength model: Let X (strength) and Y (stress) are two independent $TETLE$ random variables with parameters $(\lambda, \alpha, \theta)$ and $(\lambda^*, \alpha^*, \theta^*)$ respectively, the reliability stress strength model [14] can be obtained as follows

$$SS_{TETLE} = P(Y < X) = \int_0^{\infty} f_X(x)\, F_Y(x)\, dx$$

$$= \frac{1}{1-e^{-\lambda^*}} \int_0^{\infty} \left(1 - e^{-\lambda^*\left(1-e^{-2\theta^* x}\right)^{\alpha^*}}\right) f_X(x)\, dx$$

Using $E1$, and $E2$ we get $e^{-\lambda^*\left(1-e^{-2\theta^* x}\right)^{\alpha^*}} = \Sigma_{i,m,j=0}^{\infty} \frac{(-1)^{i+m+j}\,\Gamma(i\alpha^*+1)}{i!\; m!\; j!\; \Gamma(i\alpha^*-m+1)} (\lambda^*)^i (2m\theta^*)^j\, x^j$, then

$$SS_{TETLE} = \frac{1}{1-e^{-\lambda^*}} \int_0^{\infty} \left[1 - \Sigma_{i,m,j=0}^{\infty} \frac{(-1)^{i+m+j}\,\Gamma(i\alpha^*+1)}{i!\; m!\; j!\; \Gamma(i\alpha^*-m+1)} (\lambda^*)^i (2m\theta^*)^j\, x^j\right] f_X(x) dx$$

Thus the $TETLE$ reliability stress strength model is

$$SS_{TETLE} = \frac{1}{1-e^{-\lambda^*}} \left[1 - \Sigma_{i,m,j=0}^{\infty} \frac{(-1)^{i+m+j}\,\Gamma(i\alpha^*+1)}{i!\; m!\; j!\; \Gamma(i\alpha^*-m+1)} (\lambda^*)^i (2m\theta^*)^j E\left(X^j\right)\right] \quad (31)$$

where $E\left(X^j\right)$ as in (16) with $r = j$.

6. Maximum likelihood estimators of $TETLE$ parameters

Regarding to (14), the natural logarithm likelihood function that associated with a complete random sample of size n, say $(x_1, x_2, \ldots, x_n)$, follow $TETLE$ distribution with the vector of parameters $\Delta = (\lambda, \alpha, \theta)^T$ is

$$\ell\left(\Delta|\underline{x}\right) = n \ln\left(\frac{2\lambda\alpha\theta}{1-e^{-\lambda}}\right) - 2\theta\Sigma_{i=1}^{n} x_i - \lambda\Sigma_{i=1}^{n}\left(1-e^{-2\theta x_i}\right)^{\alpha} + (\alpha-1)\Sigma_{i=1}^{n} \ln\left(\left(1-e^{-2\theta x_i}\right)\right) \quad (32)$$

The maximum likelihood (ML) estimators of three parameters can be obtained through solving the nonlinear differential equations $\frac{\partial \ell(\Delta|\underline{x})}{\partial \lambda} = 0$, $\frac{\partial \ell(\Delta|\underline{x})}{\partial \alpha} = 0$, $\frac{\partial \ell(\Delta|\underline{x})}{\partial \theta} = 0$. The ML estimators are not in closed forms, so numerical method is used.

7. Numerical illustrations

Simulation and real applications are presented here to exhibit the abilities of the proposed $TETLE$ distribution.

7.1 Simulation study

The steps of the simulation process are:

1. Based on simulated formula in (20), generate i.i.d. random samples (1000 times) follow $TETLE$ with size $n = 10, 25, 50, 100,$ and 200 where the initial (or true) values of parameters are chosen to be as in Table 1 (also see Figure 2).
2. For parameter λ, calculate the Bias and root mean squared error (RMSE) as

$$Bias\left(\hat{\lambda}\right) = \frac{1}{1000}\Sigma_{i=1}^{1000}\left(\hat{\lambda}_i - \lambda\right) \text{ and } RMSE\left(\hat{\lambda}\right) = \sqrt{\frac{1}{1000}\Sigma_{i=1}^{1000}\left(\hat{\lambda}_i - \lambda\right)^2}\,.$$

3. Repeat step 2 for parameters α, and θ .

The empirical results are listed in Table 1. It clearly appears that RMSE values decrease as the sample size increases.

Table 1: The Bias and RMSE associated with MLE of the $TETLE$ parameters

7.2 Real applications

Here we provide applications for two real data sets to illustrate the abilities and flexibility of the TETLE distribution.

Data-1: The first real data available at the early detection unit for breast cancer at Benha University Hospital in Egypt for the period from June to October 2014. The data represent the ages of 155 patients with breast tumors [15].

"46, 32, 50, 46, 44, 42, 69, 31, 25, 29, 40, 42, 24, 17, 35, 48, 49, 50, 60, 26, 36, 56, 65, 48, 66, 44, 45, 30, 28, 40, 40, 50, 41, 39, 36, 63, 40, 42, 45, 31, 48, 36, 18, 24, 35, 30, 40, 48, 50, 60, 52, 47, 50, 49, 38, 30, 52, 52, 12, 48, 50, 45, 50, 50, 50, 53, 55, 38, 40, 42, 42, 32, 40, 50, 58, 48, 32, 45, 42, 36, 30, 28, 38, 54, 90, 80, 60, 45, 40, 50, 50, 40, 50, 50, 50, 60, 39, 34, 28, 18, 60, 50, 20, 40, 50, 38, 38, 42, 50, 40, 36, 38, 38, 50, 50, 31, 59, 40, 42, 38, 40, 38, 50, 50, 50, 40, 65, 38, 40, 38, 58, 35, 60, 90, 48, 58, 45, 35, 38, 32, 35, 38, 34, 43, 40, 35, 54, 60, 33, 35, 36, 43, 40, 45, 56".

Data-2: The second real data represents the fatigue fracture life of Kevlar 373/epoxy, which is subject to constant pressure at a 90 per cent stress level until it has all failed [16].

"0.0251, 0.0886, 0.0891, 0.2501, 0.3113, 0.3451, 0.4763, 0.5650, 0.5671, 0.6566, 0.6748, 0.6751, 0.6753, 0.7696, 0.8375, 0.8391, 0.8425, 0.8645, 0.8851, 0.9113, 0.9120, 0.9836, 1.0483, 1.0596, 1.0773, 1.1733, 1.2570, 1.2766, 1.2985, 1.3211, 1.3503, 1.3551, 1.4595, 1.4880, 1.5728, 1.5733, 1.7083, 1.7263, 1.7460, 1.7630, 1.7746, 1.8275, 1.8375, 1.8503, 1.8808, 1.8878, 1.8881, 1.9316, 1.9558, 2.0048, 2.0408, 2.0903, 2.1093, 2.1330, 2.2100, 2.2460, 2.2878, 2.3203, 2.3470, 2.3513, 2.4951, 2.5260, 2.9911, 3.0256, 3.2678, 3.4045, 3.4846, 3.7433, 3.7455, 3.9143, 4.8073, 5.4005, 5.4435, 5.5295, 6.5541, 9.0960".

The TETLE fitting is compared with six distributions: Beta Exponential (BE), Kumaraswamy Exponential (KuE), Exponentiated Generalized Exponential (EGE), Weibull Exponential (WeE), Gompertz Exponential (GoE), and Exponential (E) distributions. The R software used to calculate the MLEs of the parameters, for each distribution, along with the information criteria: (-LL) negative log-likelihood, (AIC) Akaike Information Criteria, (CAIC) Consistent Akaike Information Criteria, (BIC) Bayesian Information Criteria, (HQIC) Hanan and Quinn Information Criteria. Lowest values of these information criteria indicate the distribution with a better fit and are defined as [17]

$$AIC = 2p - 2\ell_{max}\ , CAIC = \frac{2np}{n-p-1} - 2\ell_{max}\ ,$$
$$BIC = p\ln(n) - 2\ell_{max}\ \text{, and } HQIC = 2p\ln(\ln(n)) - 2\ell_{max}\ .$$

where

p: is the number of distribution parameters, ℓ_{max}: is the log-likelihood function evaluated at MLEs, and n: is the sample size.

From the results that are shown in Tables 2 – 5, it is seen clearly that the lowest values of information criteria are associated with TETLE, which makes it the most fitting to represent two data sets compared to other distributions. Furthermore, the best fitting of TETLE can be seen through the plots of the histogram and empirical cdfs shown in Figures 3 - 6.

8 Conclusions

A newly generated family of continuous distributions with Topp Leone is introduced. Then a truncated distribution as a sub-model with three parameters called Truncated Exponential Topp Leone Exponential (TETLE) is proposed. Reliability characteristics with several main properties are presented. The TETLE distribution applied upon simulation besides two real applications with different information criteria. The results of simulation clearly shown the flexibility and consistent performance of the maximum likelihood estimates and the results of real applications clearly shown that the proposed distribution has outstanding performance than other considered distributions for all criteria. This flexibility allows using the TETLE distribution in various application areas. Furthermore, for future work, through using the same new family presented here, one can derive another new continuous probability distributions.

Runge-kutta Numerical Method for Solving Nonlinear Influenza Model

Runge-kutta Numerical Method for Solving Nonlinear Influenza Model

Shatha Jabbar Mohammed and Maha A. Mohammed

Department of Mathematics, College of Education for Pure Sciences Ibn-Al-Haitham, University of Baghdad, Baghdad, Iraq

E-mail: maha.aj.m@ihcoedu.uobaghdad.edu.iq

Abstract. The main object of this study is to solve a system of nonlinear ordinary differential equations (ODE) of the first order governing the epidemic model using numerical methods. The application under study is a mathematical epidemic model which is the influenza model at Australia in 1919. Runge-kutta methods of order 4 and of order 45 for solving this initial value problem(IVP) problem have been used. Finally, the results obtained have been discussed tabularly and graphically.

1. Introduction

Influenza is an infectious disease that is transmitted by a virus widespread in the population and infects people of different ages [1]. It is transmitted from person to person through the air of sneeze, cough, touch soiled objects and move them to the eye, nose or mouth, and others [2,3]. The researchers were representing them as mathematical models. Many people suffer from severe symptoms of the disease around the world. It can turn into a serious disease especially for old adults, newborns, people who have chronic diseases, pregnant women, and people who are obese [4,5]. Flu symptoms may be mild or very strong and these symptoms include cough, nausea, vomiting, fever, headache, fatigue, sore throat, runny nose, chills, muscle pain, sweating, fatigue, weakness, and others [6].

The cause of this disease is the influenza virus, which is transmitted from person to person through the respiratory system. Influenza virus may cause death for some people, especially those who suffer from other health problems [6].

There are many researchers interested in studying epidemiological models to know whether the epidemic is increasing or decreasing, such as Sabaa and Mohammed in 2019 discussed the analytic solutions of a nonlinear social epidemic model for alcohol consumption problem in Spain using Adomian decomposition and variation iteration methods [7]. Sabaa and Mohammed, in 2020 solved also the nonlinear social epidemic model that is the smoking habit problem by Adomian decomposition, variation iteration, finite difference, and Runge-Kutta approximate methods [8].

Many researchers analyzed the influenza epidemic model that is under study, such as El-Shahed and Alsaedi in 2011 studied the fractional SIRC model and influenza A [9], Shaman and Karspeck in 2012 studied Forecasting seasonal outbreaks of influenza [10]. Reynolds, et al. in 2014 studied mathematical modeling of influenza A virus dynamics within Swine Farms and the Effects of Vaccination [11]. Jódar, et al. in 2017 studied a mathematical model of Influenza: stability and treatment [12]. Zarebski et al. in 2017 analyzed a mathematical model of epidemics of seasonal influenza in Australia using the likelihood-based method [13], Kim et al. in 2017 studied the optimal control strategies of influenza epidemic model in Korea [14].

The feature of such a model is the existence of multiple parameters and multivariate. As well, it is a nonlinear system of the first-order ordinary differential equations for initial value problems that do not mostly get the exact solution. Our interest is to solve numerically such models. The choice of appropriate numerical methods is necessary. One of the numerical methods for solving this problem and the most famous method is Runge-Kutta of order 4 (RK_4) and Runge-kutta of order 45 (RK_{45}) to solve the Influenza model in Australia in 1919 depending on previous studies which is a reliable method. The solution is approximate because most mathematical models are very complicated since such models contain several variables and parameter, the exact solution of these models is not available [15]. There were concerns with the manual calculation of somewhat large data sets but those concerns disappeared with the widespread availability of computers that establish programs for these numerical methods to get the solution easy and fast [16].

This research is arranged as follows: In Section 2, the mathematical model of an influenza epidemic is presented, Section 3 constructs the numerical solutions of the influenza model by Runge-Kutta of 4th order $(RK4)$ and of order 45 (RK_{45}) method, Section 4, results, and discussion are presented tabularly and graphically, Section 5 has ended the study by the conclusion.

2. Mathematical Model

Mathematical modeling is an abstract model that uses mathematical language to describe the behavior of a system. The mathematical model is also defined as a collection of equations that describes a natural phenomenon. The importance of modeling in understanding the spread of the influenza epidemic [17]. The influenza epidemic in Australia in 1919 has been studied to predict the progression of disease levels. The population contains four species of individuals, $S(t), E(t), I(t)$ and $R(t)$ called compartments, the first compartment is the healthy persons and symbolized by (S), the second compartment is the infected persons, but does not cause infection, the person is in the incubation period and symbolized by (E), the third compartment is the infected persons and the cause infection after the incubation period and symbolized by (I), the fourth compartment is the persons who recover or die and symbolized by (R). So our model is made $(SEIR)$,[1]. The governing equations for the influenza model are given as a system of the first-order nonlinear ordinary differential equations in the system (1), [1]:

$$S'(t) = -\beta\frac{IS}{N} - \mu S + rN + \delta R$$
$$E'(t) = \beta\frac{IS}{N} - (\mu + \sigma + \kappa)\mathrm{E}$$
$$I'(t) = \sigma E - (\mu + \alpha + \gamma)I$$
$$R'(t) = \kappa E + \gamma I - \mu R - \delta R$$

where Table 1. has described the variables of the influenza model $S(t), E(t), I(t), R(t)$, Table 2 has the description of the parameters of the influenza model $\beta, \mu, r, \delta, \sigma, \kappa, \alpha, \gamma$ and the initial conditions (random variables) of the system (1): $S_0 = 0.4865$, $E_0 = 0.0000009$, $I_0 = 0.000068$, $R_0 = 0.0000000$, N is the total population such that $N = S + E + I + R$ and the specified time period $(0,70)$ is used to obtain results by Samsuzzoha, Singh, et al. [1].

Table 1: Describing the variables of the influenza model

Variables	Description
$S(t)$	Proportion of susceptible population
$E(t)$	Proportion of exposed population
$I(t)$	Proportion of infective population
$R(t)$	Proportion of recovered population

Table 2: Description of the parameters of the influenza model and value of parameters [1]

Parameters	Description	Value of Parameters
β	Contact rate	0.5020000
μ	Natural mortality rate	0.0003671
r	Birth rate	0.0006762
δ	Duration of immunity loss	0.0027400
σ	Mean duration of latency	0.6990000
κ	Recovery rate of latent	0.0001500
α	Flu induced mortality rate	0.0300000
γ	Mean recovery time for clinically ill	0.3600000

3. Numerical Method for Solving Influenza Model

A numerical method is a procedure that produces approximate solutions at specific points using the operations of addition, subtraction, multiplication, division, and functional appraisals. It can be applied to most first_order initial value problems [18]. They are important tools for investigating the systems [19]. Runge_Kutta is a set of iterative, implicit, and explicit methods [20]. Runge-Kutta techniques were introduced around 1900 by Carl Runge and Wilhelm Kutta [21]. In this section, two types of numerical methods can be discussed: (RK_4 and RK_{45} to solve the influenza epidemic problem in Australia in 1919, [1].

3.1. Runge-Kutta of Order 4 (RK_4) Method

RK_4 method is a reliable and accurate iteration numerical method that is used to solve the linear and nonlinear system or equation of the first ODE for initial value problems, it gives accurate results. It is a built-in method from the Runge-Kutta family. The nonlinear system of the influenza model under study can be solved by the RK method at present work. RK method has different forms according to the order of the method, in the present work, RK of the fourth order in this section can be used to solve the nonlinear system of the system (1). This work needs four steps to find the final form, [22].

The general formula of y_{i+1} for the RK_4 method [22] is:

$$y_{i+1} = y_i + \frac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4) \quad (1)$$

In order to solve the system of system (1) using RK_4 to obtain numerical results, first write the form of RK_4 as below, in equations (2-5) the general formula of $S_{i+1}, E_{i+1}, I_{i+1}$ and R_{i+1} for the RK_4 method is:

$$S_{i+1} = S_i + \frac{1}{6}(k_{S1} + 2k_{S2} + 2k_{S3} + k_{S4}) \quad (2)$$

$$E_{i+1} = E_i + \frac{1}{6}(k_{E1} + 2k_{E2} + 2k_{E3} + k_{E4}) \quad (3)$$

$$I_{i+1} = I_i + \frac{1}{6}(k_{I1} + 2k_{I2} + 2k_{I3} + k_{I4}) \quad (4)$$

$$R_{i+1} = R_i + \frac{1}{6}(k_{R1} + 2k_{R2} + 2k_{R3} + k_{R4}) \quad (5)$$

where $i = 0,1, \dots, n-1$.

The general formula of k_1, k_2, k_3, k_4 for the RK_4 method [22] is:

$$k_1 = hf_1(t_i, y_i) \quad (6)$$

$$k_2 = hf_2(t_i + \frac{h}{2}, y_i + \frac{k_1}{2}) \quad (7)$$

$$k_3 = hf_3(t_i + \frac{h}{2}, y_i + \frac{k_2}{2}) \quad (8)$$

$$k_4 = hf_4(t_i + h, y_i + k_3) \quad (9)$$

where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size.
Now, to find k_{S1}, k_{E1}, k_{I1} and k_{R1}, we following the next steps in equations (10-13).

$$k_{S1} = hf_1(t_i, S_i, E_i, I_i, R_i) = h\left(\frac{-\beta}{N_{i1}} I_i S_i - \mu S_i + rN_{i1} + \delta R_i\right) \quad (10)$$

$$k_{E1} = hf_2(t_i, S_i, E_i, I_i, R_i) = h\left(\frac{\beta}{N_{i1}} I_i S_i - (\mu + \sigma + \kappa)E_i\right) \quad (11)$$

$$k_{I1} = hf_3(t_i, S_i, E_i, I_i, R_i) = h\,(\,\sigma E_i - (\mu + \alpha + \gamma)I_i\,) \quad (12)$$

$$k_{R1} = hf_4(t_i, S_i, E_i, I_i, R_i) = h(\,\kappa E_i + \gamma I_i - \mu R_i - \delta R_i) \quad (13)$$

where $i = 0,1, \dots, n-1$.
In the same way, k_{S2}, k_{E2}, k_{I2} and k_{R2} can be found to obtain the second step in equations (14-17) where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size:

$$\begin{aligned} k_{S2} &= hf_1(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S1}, E_i + \frac{1}{2}k_{E1}, I_i + \frac{1}{2}k_{I1}, R_i + \frac{1}{2}k_{R1}) \\ &= h\,(\frac{-\beta}{N_{i2}}\left(I_i + \frac{1}{2}k_{I1}\right)(S_i + \frac{1}{2}k_{S1}\right) - \mu\left(S_i + \frac{1}{2}k_{S1}\right) + rN_{i2} \\ &\quad + \delta\left(R_i + \frac{1}{2}k_{R1}\right)) \end{aligned} \quad (14)$$

$$\begin{aligned} k_{E2} &= hf_2\,(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S1,}\, E_i + \frac{1}{2}k_{E1,}\, I_i + \frac{1}{2}k_{I1}, R_i + \frac{1}{2}k_{R1}) \\ &= h\,(\frac{\beta}{N_{i2}}\left(I_i + \frac{1}{2}k_{I1}\right)(S_i + \frac{1}{2}k_{S1}\right) - (\mu + \sigma + \kappa)\left(E_i + \frac{1}{2}k_{E1}\right)) \end{aligned} \quad (15)$$

$$\begin{aligned} k_{I2} &= hf_3\,(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S1}, E_i + \frac{1}{2}k_{E1}, I_i + \frac{1}{2}k_{I1}, R_i + \frac{1}{2}k_{R1}) \\ &= h\,(\sigma\left(E_i + \frac{1}{2}k_{E1}\right) - (\mu + \alpha + \gamma)\left(I_i + \frac{1}{2}k_{I1}\right)) \end{aligned} \quad (16)$$

$$\begin{aligned} k_{R2} &= hf_4\,(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S1}, E_i + \frac{1}{2}k_{E1}, I_i + \frac{1}{2}k_{I1}, R_i + \frac{1}{2}k_{R1}) \\ &= h\,\left(\kappa\left(E_i + \frac{1}{2}k_{E1}\right) + \gamma\left(I_i + \frac{1}{2}k_{I1}\right) - \mu\left(R_i + \frac{1}{2}k_{R1}\right)\right. \\ &\quad \left. - \delta\left(R_i + \frac{1}{2}k_{R1}\right)\right) \end{aligned} \quad (17)$$

where $i = 0,1, \dots, n-1$.
In the third stage, try to find k_{S3}, k_{E3}, k_{I3} and k_{R3} by substituting in the system (1) as below in equations (18-21) where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size:

$$k_{S3} = hf_1\left(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S2}, E_i + \frac{1}{2}k_{E2}, I_i + \frac{1}{2}k_{I2}, R_i + \frac{1}{2}k_{R2}\right)$$
$$= h\left(\frac{-\beta}{N_{i3}}\left(I_i + \frac{1}{2}k_{I2}\right)\left(S_i + \frac{1}{2}k_{S2}\right) - \mu\left(S_i + \frac{1}{2}k_{S2}\right) + rN_{i3} + \delta\left(R_i + \frac{1}{2}k_{R2}\right)\right) \quad (18)$$

$$k_{E3} = hf_2\left(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S2}, E_i + \frac{1}{2}k_{E2}, I_i + \frac{1}{2}k_{I2}, R_i + \frac{1}{2}k_{R2}\right)$$
$$= h\left(\frac{\beta}{N_{i3}}\left(I_i + \frac{1}{2}k_{I2}\right)\left(S_i + \frac{1}{2}k_{S2}\right) - (\mu + \sigma + \kappa)\left(E_i + \frac{1}{2}k_{E2}\right)\right) \quad (19)$$

$$k_{I3} = hf_3\left(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S2}, E_i + \frac{1}{2}k_{E2}, I_i + \frac{1}{2}k_{I2}, R_i + \frac{1}{2}k_{R2}\right)$$
$$= h\left(\sigma\left(E_i + \frac{1}{2}k_{E2}\right) - (\mu + \alpha + \gamma)\left(I_i + \frac{1}{2}k_{I2}\right)\right) \quad (20)$$

$$k_{R3} = hf_4\left(t_i + \frac{h}{2}, S_i + \frac{1}{2}k_{S2}, E_i + \frac{1}{2}k_{E2}, I_i + \frac{1}{2}k_{I2}, R_i + \frac{1}{2}k_{R2}\right)$$
$$= h\left(\kappa\left(E_i + \frac{1}{2}k_{E2}\right) + \gamma\left(I_i + \frac{1}{2}k_{I2}\right) - \mu\left(R_i + \frac{1}{2}k_{R2}\right) - \delta\left(R_i + \frac{1}{2}k_{R2}\right)\right) \quad (21)$$

where $i = 0,1,\dots,n-1$.
The fourth stage needs to find k_{S4}, k_{E4}, k_{I4} and k_{R4} as below, in equations (22-25) where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size:

$$k_{S4} = hf_1\left(t_i + h, S_i + k_{S3}, E_i + k_{E3}, I_i + k_{I3}, R_i + k_{R3}\right)$$
$$= h\left(\frac{-\beta}{N_{i4}}\left(I_i + k_{I3}\right)(S_i + k_{S3}) - \mu(S_i + k_{S3}) + rN_{i4} + \delta(R_i + k_{R3})\right) \quad (22)$$

$$k_{E4} = hf_2\left(t_i + h, S_i + k_{S3}, E_i + k_{E3}, I_i + k_{I3}, R_i + k_{R3}\right)$$
$$= h\left(\frac{\beta}{N_{i4}}\left(I_i + k_{I3}\right)(S_i + k_{S3}) - (\mu + \sigma + \kappa)(E_i + k_{E3})\right) \quad (23)$$

$$k_{I4} = hf_3\left(t_i + h, S_i + k_{S3}, E_i + k_{E3}, I_i + k_{I3}, R_i + k_{R3}\right)$$
$$= h\left(\sigma(E_i + k_{E3}) - (\mu + \alpha + \gamma)(I_i + k_{I3})\right) \quad (24)$$

$$k_{R4} = hf_4\left(t_i + h, S_i + k_{S3}, E_i + k_{E3}, I_i + k_{I3}, R_i + k_{R3}\right)$$
$$= h\left(\kappa(E_i + k_{E3}) + \gamma(I_i + k_{I3}) - \mu(R_i + k_{R3}) - \delta(R_i + k_{R3})\right) \quad (25)$$

where $i = 0,1,\dots,n-1$.

3.2 Runge-Kutta of Order 45 (RK_{45}) Method

RK_{45} method is a reliable and accurate iteration numerical method that is used to solve the nonlinear system of the system (1). This work needs six steps to find the final form, [22]. It was developed by a German mathematician Erwin Fehlberg in 1969. It is a built-in method from Runge-Kutta family.

The general formula of y_{i+1} for the RK_{45} method [23] is:

$$y_{i+1} = y_i + \frac{25}{216}k_1 + \frac{1408}{2565}k_3 + \frac{2197}{4104}k_4 - \frac{1}{5}k_5 \quad (26)$$

In order to solve the system of the system (1) using RK_{45} to obtain numerical results, first write the form of RK_{45} as below, in equations (27-30), the general formula of $S_{i+1}, E_{i+1}, I_{i+1}$ and R_{i+1} for the RK_4 method is:

$$S_{i+1} = S_i + \frac{25}{216} k_{S1} + \frac{1408}{2565} k_{S3} + \frac{2197}{4104} k_{S4} - \frac{1}{5} k_{S5} \quad (27)$$

$$E_{i+1} = E_i + \frac{25}{216} k_{E1} + \frac{1408}{2565} k_{E3} + \frac{2197}{4104} k_{E4} - \frac{1}{5} k_{E5} \quad (28)$$

$$I_{i+1} = I_i + \frac{25}{216} k_{E1} + \frac{1408}{2565} k_{E3} + \frac{2197}{4104} k_{E4} - \frac{1}{5} k_{I5} \quad (29)$$

$$R_{i+1} = R_i + \frac{25}{216} k_{R1} + \frac{1408}{2565} k_{R3} + \frac{2197}{4104} k_{R4} - \frac{1}{5} k_{R5} \quad (30)$$

where $i = 0,1, \dots, n-1$.

The general formula of $k_1, k_2, k_3, k_4, k_5, k_6$ for the RK_{45} method [22] is:

$$k_1 = h f_1(t_i, y_i) \quad (31)$$

$$k_2 = h f_2(t_i + \frac{h}{4}, y_i + \frac{k_1}{4}) \quad (32)$$

$$k_3 = h f_3(t_i + \frac{3h}{8}, y_i + \frac{3k_1}{32} + \frac{9k_2}{32}) \quad (33)$$

$$k_4 = h f_4(t_i + \frac{12h}{13}, y_i + \frac{1932k_1}{2197} - \frac{7200k_2}{2197} + \frac{7296k_3}{2197}) \quad (34)$$

$$k_5 = h f_5(t_i + h, y_i + \frac{439k_1}{219} - 8k_2 + \frac{3680k_3}{513} - \frac{845k_4}{4104}) \quad (35)$$

$$k_6 = h f_6(t_i + \frac{h}{2}, y_i - \frac{8k_1}{27} + 2k_2 - \frac{3544k_3}{2565} + \frac{1859k_4}{4104} - \frac{11k_5}{40}) \quad (36)$$

where $f_1, f_2, f_3, f_4, f_5, f_6$ are unknown functions, t is a time and h is a step size.

Now, To find k_{S1}, k_{E1}, k_{I1} and k_{R1} following the next steps in equations (37-40) where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size:

$$k_{S1} = h f_1(t_i, S_i, E_i, I_i, R_i) = h\left(\frac{-\beta}{N_{i1}} I_i S_i - \mu S_i + r N_{i1} + \delta R_i\right) \quad (37)$$

$$k_{E1} = h f_2(t_i, S_i, E_i, I_i, R_i) = h\left(\frac{\beta}{N_{i1}} I_i S_i - (\mu + \sigma + \kappa) E_i\right) \quad (38)$$

$$k_{I1} = h f_3(t_i, S_i, E_i, I_i, R_i) = h\,(\sigma E_i - (\mu + \alpha + \gamma) I_i) \quad (39)$$

$$k_{R1} = h f_4(t_i, S_i, E_i, I_i, R_i) = h(\kappa E_i + \gamma I_i - \mu R_i - \delta R_i) \quad (40)$$

where $i = 0,1, \dots, n-1$.

In the same way, k_{S2}, k_{E2}, k_{I2} and k_{R2} can be found to obtain the second step in equations (41-44) where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size:

$$\begin{aligned} k_{S2} = h f_1(t_i + \frac{h}{4}, S_i + \frac{1}{4}k_{S1}, E_i + \frac{1}{4}k_{E1}, I_i + \frac{1}{4}k_{I1}, R_i + \frac{1}{4}k_{R1}) \\ = h\,(\frac{-\beta}{N_{i2}}\left(I_i + \frac{1}{4}k_{I1}\right)\left(S_i + \frac{1}{4}k_{S1}\right) - \mu\left(S_i + \frac{1}{4}k_{S1}\right) + r N_{i2} \\ + \delta\left(R_i + \frac{1}{4}k_{R1}\right)) \end{aligned} \quad (41)$$

$$k_{E2} = hf_2\ (t_i + \frac{h}{4}, S_i + \frac{1}{4}k_{S1,}\ E_i + \frac{1}{4}k_{E1,}\ I_i + \frac{1}{4}k_{I1}, R_i + \frac{1}{4}k_{R1}$$
$$= h\ (\frac{\beta}{N_{i2}}\left(\ I_i + \frac{1}{4}k_{I1}\ \right)\ (S_i + \frac{1}{4}k_{S1}\right) - (\mu + \sigma + \kappa)\left(E_i + \frac{1}{4}k_{E1}\right)) \quad (42)$$

$$k_{I2} = hf_3\ (t_i + \frac{h}{4}, S_i + \frac{1}{4}k_{S1}, E_i + \frac{1}{4}k_{E1}, I_i + \frac{1}{4}k_{I1}, R_i + \frac{1}{4}k_{R1})$$
$$= h\ (\sigma\left(E_i + \frac{1}{4}k_{E1}\right) - \ (\mu + \alpha + \gamma)\left(I_i + \frac{1}{4}k_{I1}\right)) \quad (43)$$

$$k_{R2} = hf_4\ (t_i + \frac{h}{4}, S_i + \frac{1}{4}k_{S1}, E_i + \frac{1}{4}k_{E1}, I_i + \frac{1}{4}k_{I1}, R_i + \frac{1}{4}k_{R1})$$
$$= h\ \left(\kappa\left(E_i + \frac{1}{4}k_{E1}\ \right) + \ \gamma\ \left(I_i + \frac{1}{4}k_{I1}\right) - \mu\left(R_i + \frac{1}{4}k_{R1}\right)\right. \quad (44)$$
$$\left. - \delta\left(R_i + \frac{1}{4}k_{R1}\right)\right)$$

where $i = 0,1, \dots, n-1$.
In the third stage, try to find k_{S3}, k_{E3}, k_{I3} and k_{R3} by substituting in the system (1) as below in equations (45-48) where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size:

$$k_{S3} = hf_1\ (t_i + \frac{3h}{8}, S_i + \frac{3}{32}k_{S1} + \frac{9}{32}k_{S2}, E_i + \frac{3}{32}k_{E1} + \frac{9}{32}k_{E2}, I_i + \frac{3}{32}k_{I1}$$
$$+ \frac{9}{32}k_{I2}, R_i + \frac{3}{32}k_{R1} + \frac{9}{32}k_{R2})$$
$$= h\ (\frac{-\beta}{N_{i3}}(\ I_i + \frac{3}{32}k_{I1} + \frac{9}{32}k_{I2})(\ S_i + \frac{3}{32}k_{S1} + \frac{9}{32}k_{S2}) \quad (45)$$
$$- \ \mu\left(S_i + \frac{3}{32}k_{S1} + \frac{9}{32}k_{S2}\right) + \ rN_{i3} + \delta\left(R_i + \frac{3}{32}k_{R1} + \frac{9}{32}k_{R2}\right)),$$

$$k_{E3} = hf_2\ (t_i + \frac{3h}{8}, S_i + \frac{3}{32}k_{S1} + \frac{9}{32}k_{S2}, E_i + \frac{3}{32}k_{E1} + \frac{9}{32}k_{E2}, I_i + \frac{3}{32}k_{I1}$$
$$+ \frac{9}{32}k_{I2}, R_i + \frac{3}{32}k_{R1} + \frac{9}{32}k_{R2}$$
$$= h\ (\frac{\beta}{N_{i3}}\left(I_i + \frac{3}{32}k_{I1} + \frac{9}{32}k_{I2}\ \right)(\ S_i + \frac{3}{32}k_{S1} + \frac{9}{32}k_{S2}) \quad (46)$$
$$- (\mu + \sigma + \kappa)\left(E_i + \frac{3}{32}k_{E1} + \frac{9}{32}k_{E2}\right))$$

$$k_{I3} = hf_3\ \ (t_i + \frac{3h}{8}, S_i + \frac{3}{32}k_{S1} + \frac{9}{32}k_{S2}, E_i + \frac{3}{32}k_{E1} + \frac{9}{32}k_{E2}, I_i + \frac{3}{32}k_{I1}$$
$$+ \frac{9}{32}k_{I2}, R_i + \frac{3}{32}k_{R1} + \frac{9}{32}k_{R2}) \quad (47)$$
$$= h\ (\sigma(E_i + \frac{3}{32}k_{E1} + \frac{9}{32}k_{E2}) - \ (\mu + \alpha + \gamma)\left(I_i + \frac{3}{32}k_{I1} + \frac{9}{32}k_{I2}\right))$$

$$
\begin{aligned}
k_{R3} = hf_4\ \Big(t_i + \frac{3h}{8}, S_i + \frac{3}{32}k_{S1} + \frac{9}{32}k_{S2}, E_i + \frac{3}{32}k_{E1} + \frac{9}{32}k_{E2}, I_i + \frac{3}{32}k_{I1} \\
+ \frac{9}{32}k_{I2}, R_i + \frac{3}{32}k_{R1} + \frac{9}{32}k_{R2}\Big) \\
= h\left(\kappa\left(E_i + \frac{3}{32}k_{E1} + \frac{9}{32}k_{E2}\right) + \gamma\left(I_i + \frac{3}{32}k_{I1} + \frac{9}{32}k_{I2}\right)\right. \\
\left. - \mu\left(R_i + \frac{3}{32}k_{R1} + \frac{9}{32}k_{R2}\right) - \delta\left(R_i + \frac{3}{32}k_{R1} + \frac{9}{32}k_{R2}\right)\right)
\end{aligned} \tag{48}
$$

where $i = 0,1, \dots, n-1$.
The fourth stage needs to find k_{S4}, k_{E4}, k_{I4} and k_{R4} as below, in equations (49-52) where f_1, f_2, f_3, f_4 are unknown functions, t is a time and h is a step size:

$$
\begin{aligned}
k_{S4} = hf_1\ \Big(t_i + \frac{12h}{13}, S_i + \frac{1932}{2197}k_{S1} - \frac{7200}{2197}k_{S2} + \frac{7296}{2197}k_{S3}, \\

4. Results and Discussion

Numerical solutions for the nonlinear influenza model in Australia in 1919 are discussed and analyzed in this section. Table 3 is to compare the values of variables $S(t), E(t), I(t), R(t)$ between RK_4 and RK_{45} methods. Where step size h in { 0.5, 0.25, 0.04 } and interval [0,70] days. For $E(t)$ has the smallest value with ($h = 0.04$), every 12 hours during 70 days in the RK_{45} compared with the RK_4. It is clear from Table 3 that RK_{45} method is better than RK_4 method. The Matlab program is used to numerically solve the influenza pandemic model.

Figures 1, 2 describes the influenza epidemic in Australia in 1919. In Figure 1 $(a), (b), (c)$ of RK_4, the curve is high then it starts to decrease after 20 days in the proportion of susceptible population $S(t)$. While the curve is low then it starts to increase then it goes down after 40 days in the proportion of exposed population $E(t)$ and the proportion of infective population $I(t)$, the curve is low then it starts to increase after 20 days in the proportion of recovered population $R(t)$, this means that susceptible population will be infected with influenza epidemics in the coming years. This method is convergence with RK_{45} method was in Figure 2 $(a), (b), (c)$ of RK_{45} , the curve is high then it starts to decrease after 20 days in the proportion of susceptible population $S(t)$. while the curve is low then it starts to increase then it goes down after 40 days in the proportion of exposed population $E(t)$ and the proportion of infective population $I(t)$, the curve is low then it starts to increase after 20 days in the proportion of recovered population $R(t)$, this means that susceptible population will be infected with influenza epidemics in the coming years. These methods are convergent in solution because they are iterative numerical methods. These methods agree with previous studies [1].

Table3: Numerical solution and values of influenza mode

Variable	h/day^{-1}	RK_4	RK_{45}
$S(t)$	0.5	0.59720331	0.59720329

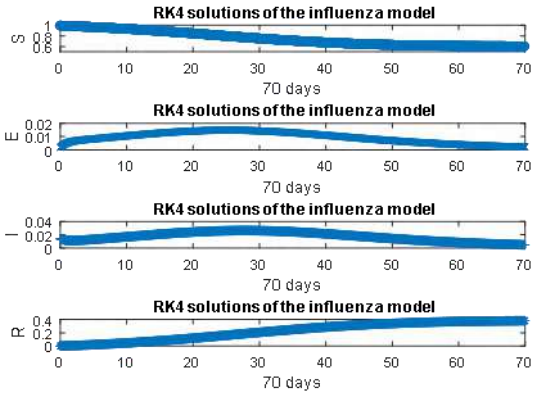
$(b)\ h = 0.25, m = 280$



$(c)\ h = 0.04, m = 1750$

Figure 2. Numerical solution of the influenza model around the value of parameters using RK_{45} of $S(t), E(t), I(t), R(t)$ in 1919 when step size $h = 0.5, 0.25, 0.04$, iteration $m = 140, 280, 1750$.

Conclusion

In the current study, some reliable, accurate, and approximate methods are used for solving a nonlinear system of epidemic models for ordinary differential equations of the first order. There is a convergence in the results of the numerical methods which are Runge-Kutta of order 4 and of order 45 as shown in Table 3. The numerical methods RK_4 and RK_{45} help us to analyze the spread of the epidemic in the influenza model. The results obtained showed that individual $S(t)$ of the proportion of the susceptible population, individual $E(t)$ of the proportion of the exposed population, and individual $I(t)$ of the proportion of the infective population are gradually decreased to 70 days. While individual $R(t)$ the proportion of the recovered population gradually increased until. A MATLAB program has been helped to solve this problem.

Abstract. The purpose of this paper is to prove a common fixed point(c.f.p) theorems by using conditiond $\big(S(x),T(y)\big) \le \ell \max\{d\big(h(x),G(y)\big),d\big(h(x),S(x)\big),d\big(G(y),T(y)\big),$ $d\big(h(x),T(y)\big),d\big(G(y),S(x)\big)\}$ For two pairs of mappings in p-normed space(p-n.s) and also obtain the best approximation (b.a) result. In the last part of this paper, it is proved that the fixed point (f.p) problem for these mappings is well-posed (w-p).

1. Introduction

c.f.p theorems for generalized affine mapping and a class of I-non expansive non commuting mappings were proved by Nashine and Dewangan [9]. Cho, Hussain, and Pathak [3] c.f.p theorems and b.a results in normed linear spaces are proved.

In 2013, Bari and Vetro [2] proved some c.f.p and coincidence point results for three or four mappings. Further, Singh [11] proved the c.f.p theorem for multivalued mappings generalized.

In 2017 AL-saidy, Abed, and Ajeel [1] proved three common random f.p theorems for commuting random operators defined on a non-starshaped subset of a p-n.s X. In this research, some c.f.p theorems for two pairs mappings defined on non-star-shaped domain subset of a p-n.s are proved.

2. Preliminaries

We need the following definitions and facts:

Definition (2.1): Let X be a linear space and $\|\ \|_p$ be a real-valued function on X with $0 < p \le 1$. The pair (X, $\|\ \|_p$) is called a p-n.s if for all a, b in X and scalars ζ:

i. $\|a\|_p \ge 0$ and $\|a\|_p = 0$ iff $a = 0$
ii. $\|\zeta a\|_p = |\zeta|^p \|a\|_p$
iii. $\|a+b\|_p \le \|a\|_p + \|b\|_p$

Every p-normed space X induces a metric space with $(a,b) = \|a-b\|_p$, for all a, b in X. If $p = 1$, we have the concept of a normed space [5]. Since a p-n.s is not necessarily locally convex space and the continuous dual $X`$ of p-normed space, X need not separate the point of X [7].

Example (2.1):
Let $X = R^3$ with$\|(a_1, a_2, a_3)\|_p = \sum_{i=1}^{3} |a_i|^p$ (|.| is the absolute value), for any pair (a_1, a_2, a_3) in X and $0 < p \leq 1$, then X is p-normed space since it is satisfying all conditions of definition (2.1).

Definition (2.2):[12]: Let X be a metric space, A subset A of X is called starshaped if there exist at least one point $q \in A$ such that
[a,q]$= \lambda a + (1 - \lambda)q \in A,$ for all $a \in A$ and $0 \leq \lambda \leq 1$. In this case, q is said the starcenter of A.

Definition (2.3): [15]: A self-mapping h of a linear space X is said to be affine if for all a, b in X and for any ζ, $0 \leq \zeta \leq 1$, $h\ [\zeta a + (1 - \zeta)\ b] = \zeta\ h(a) + (1 - \zeta)\ h(b)$.
And h is called q-affine if there is $q \in X$ such that $h[\zeta a + (1 - \zeta)q] = \zeta h(a) + (1 - \zeta)q$, for all $\zeta \in [0,1]$ and all $\in X$.

Definition (2.4): [10]: Let $A \neq \emptyset$ subset of a p-n.s X. The set of b.a to $a_\circ \in X$, denoted as $p_A(a_\circ)$ is defined by
$p_A(a_\circ) = \{y \in A: \| a_\circ - y \|_p : dist(a_\circ, A)\}$, where
$dist(a_\circ, A) = \inf\{\| a_\circ - a \|_p : a \in A\}$.

Definition (2.5): Let $A \neq \emptyset$ subset of a metric space X and let S and T be self-mappings of A. A point $a \in A$ is a c.f (coincidence(c)) point of S and T if $Sx = Tx = x$ $(Sx = Tx)$[14]. The set of c.f.p of S and T is denoted by $F(S,T)$, the set of c.p of S and T is denoted by $C(S,T)$ and the closure of the set A is denoted by $Cl(A)$.
A mapping $S: A \to A$ is called:
(1) Hemi-compact [4] if any sequence $\{x_n\}$ in A has a convergent subsequence whenever $d(x_n, S(x_n)) \to 0$ as $n \to \infty$;
(2) completely continuous [4] if $\{x_n\}$ weakly converges to a which implies that $\{S(x_n)\}$ converges strongly to$S(a)$;
(3) Demi-closed at x, if for every sequence $\{x_n\}$ in A such that $\{x_n\}$ converges weakly to x and $\{S(x_n)\}$ converges strongly to y , we have $S(x) = y$ [8].
The pair (S,T) is said to be
(1) R-weakly commuting mappings [4] if $\forall a \in A$, $\exists \Re > 0$ such that $d(STa, TSa) < \Re d(Sa, Ta)$, if $\Re$ =1, then the mappings is said weakly commuting.
(2) R-weakly compatible [13] if they commute at their coincidence points, that is, $STa = TSa$ whenever $Sa = Ta$.
(3) C_q–commuting [4] if $STa = TSa$ for all $a \in C_q(S,T)$, where $C_q(S,T) = \cup \{C(S,T_k): 0 \leq k \leq 1\}$ and $T_k(a) = (1 - k)q + kT(a)$.

Definition (2.6): Let X a p-normed space, $A \subseteq X$, $\mathfrak{H}: X \to X$ be a mapping we say that A has property (a_1) if
i. $\mathfrak{H} : A \to A$
ii. $(1 - k_n)q + k_n \mathfrak{H}(x) \in A$, for some q ∈ A and a fixed real sequence $< k_n >$ converging to 1 and for each $x \in A$.

Remark(2.1): Any q-starshaped set has the property (a_1) w.r.t any mapping $\mathfrak{H}: A \to A$, but the converse is not true in general.

Definition (2.7): Let X be a p-normed space, $A \subseteq X$ and A has property (a_1) w.r.t a mapping $G: X \to X$, q ∈ A, and sequence $< k_n >$. A mapping$h$: $X \to X$ is called have the property (a_2) on A with property (a_1) if $h\big((1 - k_n)q + k_n\ G(x)\big)$= (1-$k_n$) $h(q)$+$k_n h(G(x))$ for all $x \in A$ and $n \in N$.

in this paper we need the following theorems:

Theorem (2.1)[6]: Let $\emptyset \neq A \subseteq X$, with $S, T, h, G: A \longrightarrow A$ such that $\forall x, y \in A$ and $0 \leq \ell < \frac{1}{2}$, the pair (S, T) satisfy the following condition

$$d\big(S(x), T(y)\big) \leq \ell \max\{d\big(h(x), G(y)\big), d\big(h(x), S(x)\big), d\big(G(y), T(y)\big) d\big(h(x), T(y)\big), d\big(G(y), S(x)\big)\} \quad (2\text{-}1)$$

If $Cl\big(S(A)\big) \subseteq G(A), Cl\big(T(A)\big) \subseteq h(A)$ and one of the subsets $Cl\big(S(A)\big), Cl\big(T(A)\big), CL\big(h(A)\big)$ or $Cl\big(G(A)\big)$ is complete, then $C(S, h) \neq \emptyset$ and $C(T, G) \neq \emptyset$.

Theorem (2.2)[6]: Let $X, A, S, T, G, h, Cl\big(S(A)\big), Cl\big(T(A)\big), CL\big(h(A)\big)$ and $Cl\big(G(A)\big)$ as in theorem (2.1). If the pairs $\{S, h\}$ and $\{T, G\}$ are weakly compatible (or R-weakly commuting), then $F(S) \cap F(h) \cap F(T) \cap F(G) \neq \emptyset$.

3- Main result

Now, by using Theorem (2.1) and Theorem (2.2) [6] we show the following:

Theorem (3.1): Let S, T, h, and G be self-maps on a subset A of a p-normed space X suppose that $cl(S(A)) \subseteq G(A), cl\big(T(A)\big) \subseteq h(A), q \in F(h) \cap F(G)$, and h and G has property (a_2). Suppose that the pairs $\{S, h\}$ and $\{T, G\}$ are C_q-commuting and satisfy

$$\|S(a) - T(b)\|_p \leq k\, max\begin{Bmatrix} \|h(a) - G(b)\|_p, dist(h(a), [q, S(a)]), \\ \text{dist}(G(b), [q, T(b)]), \text{dist}(h(a), [q, T(b)]), \text{dist}(G(b), [q, S(a)]) \end{Bmatrix} \quad (3\text{-}1)$$

For all $a, b \in A$ and $0 \leq k < \frac{1}{2}$. If S and T are continuous and A has property (a_1) with respect to S and , then $F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$, if one of the following conditions is satisfied:

i. $Cl\big(S(A)\big)$ and $Cl\big(T(A)\big)$ are compact and h and G are continuous;

ii. A is complete, $F(h)$ and $F(G)$ are bounded, and S and T are compact maps;

iii. A is bounded and complete, S and T are hemicompact, and h and G are continuous;

iv. A is weakly compact, X is complete, $h - S$ and $G - T$ are demiclosed at 0, and h and G are weakly continuous.

v. X is complete, A is weakly compact, S and T are completely continuous, and h and G are continuous.

Prof: Define $S_n: A \to A$ and $T_n: A \to A$ by $S_n(a) = (1 - k_n)q + k_n S(a)$ and $T_n(a) = (1 - k_n)q + k_n T(a)$ and a fixed sequence of real numbers k_n $(0 \leq k_n \leq 1)$ Converging to 1, for some $q \in A$ and all $a \in A$. Since A has property (a_1) with respect to S and T, $cl(S(A)) \subseteq G(A), cl\big(T(A)\big) \subseteq h(A), q \in F(h) \cap F(G)$, and h and G has property (a_2). Then for each n, $Cl\big(S_n(A)\big) \subseteq G(A)$ and$Cl\big(T_n(A)\big) \subseteq h(A)$. As the pairs $\{S, h\}$ and $\{T, G\}$ are C_q-commuting and h and G has property (a_2), with $q \in F(h) \cap F(G)$, then for each $a \in C_q(S, h) \cap C_q(T, G)$,

$$h(S_n(a)) = h\big((1 - k_n)q + k_n S(a)\big) = (1 - k_n)h(q) + k_n h(S(a)) = (1 - k_n)q + k_n S(h(a)) = S_n(h(a))$$

By similarly away we can show that $G(T_n(a)) = T_n(G(a))$ thus,

$h(S_n(a)) = S_n(h(a))$ and $G(T_n(a)) = T_n(G(a))$ for each $a \in C(S_n, h) \subseteq C_q(S, h)$ and $a \in C(T_n, G) \subseteq C_q(T_n, G)$. Hence the pairs $\{S_n, h\}$ and $\{T_n, G\}$ are weakly compatible ∀n. Also by (3.1),

$$\|S_n(a)-T_n(b)\|_p \le |k_n|^p \|S(a)-T(b)\|_p \le \|S(a)-T(b)\|_p$$
$$\le k\ max\left\{\begin{matrix}\|h(a)-G(b)\|_p, dist(h(a),[q,S(a)]),\\ \text{dist}(G(b),[q,T(b)]), \text{dist}(h(a),[q,T(b)]), \text{dist}(G(b),[q,S(a)])\end{matrix}\right\}$$
$$\le k\ max\left\{\begin{matrix}\|h(a)-G(b)\|_p, \|h(a)-S_n(a)\|_p,\\ \text{d}\|G(b)-T_n(b)\|_p, \|h(a)-T_n(b)\|_p, \|G(b)-S_n(a)\|_p\end{matrix}\right\}$$

For all $a, b \in A$.

i. Since $Cl(S(A))$ and $Cl(T(A))$ are compact, then $Cl(S_n(A))$ and $Cl(T_n(A))$ are also compact, Hence all conditions of theorem (2.2) are satisfied on the mappings S_n, T_n, h and G, therefore $\exists a_n \in A$ s.t $a_n = S_n(a_n) = T_n(a_n) = h(a_n) = G(a_n)$.Since $Cl(S(A))$ and $Cl(T(A))$ are compact , $\{S(a_n)\}$ and $\{T(a_n)\}$ sequence in $S(A)$ and $T(A)$ (respectively) , $S(A) \subseteq Cl(S(A))$ and $T(A) \subseteq Cl(T(A))$ implies that, there exists a subsequence $\{S(a_m)\}$ of $\{S(a_n)\}$ and $\{T(a_m)\}$ of $\{T(a_n)\}$ s.t $\lim_{m\to\infty} S(a_m) = \lim_{m\to\infty} T(a_m) = b$ .Since $a_m = S_n(a_m) = (1-k_m)q + k_m S(a_m)$ and $a_m = T_n(a_m) = (1-k_m)q + k_m T(a_m)$. We have $\lim_{m\to\infty} a_m = b$, hence by the continuity of h and G having $b \in F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$. Therefore $b \in F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$.

ii. As in (i), there exists $a_n \in A$ s.t $a_n = S_n(a_n) = T_n(a_n) = h(a_n) = G(a_n)$. Since S and T are compact and $\{a_n\}$ being in $F(h)$ and $F(G)$ are bounded, so there exists a subsequence $\{S(a_m)\}$ of $\{S(a_n)\}$ and $\{T(a_m)\}$ of $\{T(a_n)\}$ such that $\lim_{m\to\infty} S(a_m) = \lim_{m\to\infty} T(a_m) = b$. the definition of $S_m(a_m)$ and $T_m(a_m) \Rightarrow \lim_{m\to\infty} a_m = b$, the continuity of S, T, h and G having $b \in F(S) \cap F(T) \cap F(h) \cap F(G)$.Thus $F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$.

iii. As in (i), $\exists a_n \in A$ s.t $a_n = S_n(a_n) = T_n(a_n) = h(a_n) = G(a_n)$, and A is bounded, so $a_n - S(a_n) = (1-k_n)(S(a_n) - q) \to 0$ and $a_n - T(a_n) = (1-k_n)(T(a_n) - q) \to 0$ as $n \to \infty$. The hemicompact of S and T implies that has $\{a_n\}$ a subsequence $\{a_m\}$ such that $\lim_{m\to\infty} a_m = b$ the continuity of S, T, h and G implies that $b \in F(S) \cap F(T) \cap F(h) \cap F(G)$. Hence $F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$.

iv. As in (i), $\exists a_n \in A$ s.t $a_n = S_n(a_n) = T_n(a_n) = h(a_n) = G(a_n)$. Since A is weakly compact, then $\exists$ a subsequence $\{a_m\}$ of $\{a_n\}$ in A converging weakly to b as $m \to \infty$, from weakly continuous of h and G we have $b = h(b) = G(b)$. By (iii) $h(a_m) - S(a_m)$ and $G(a_m) - T(a_m)$converging to 0 as $m \to \infty$. The demi-closedness of $h - S$ and $G - T$ at 0 $\Rightarrow S(b) = T(b) = h(b) = G(b)$. Thus $F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$.

v. As in (iv) there is a subsequence $\{a_m\}$ of $\{a_n\}$ in A converging weakly to b as $m \to \infty$. by S and T are completely continuous, then $S(a_m) \to S(b)$ and $T(a_m) \to T(b)$ as $m \to \infty$. Since $k_n \to 1$ and $a_m = S_m(a_m) = T_m(a_m) = (1-k_m)q + k_m S(a_m) = (1-k_m)q + k_m T(a_m)$, therefore $a_m \to S(b) = T(b)$ as $m \to \infty \Rightarrow S(a_m) \to S(S(b))$ and $T(a_m) \to T(T(b))$ as $m \to \infty$, but $S(a_m) \to S(b)$ and $T(a_m) \to T(b)$ as $m \to \infty$ therefore $S(b) = S(S(b))$ and $T(b) = T(T(b))$, since $S(b) = T(b)$, then $S(b) = S(S(b)) = T(b) = T(T(b))$, implies that $c = S(c) = T(c)$, where $c = T(b) = S(b)$. Also, since $a_m \to c$ as $m \to \infty$ and h and G are continuous mappings then $c = h(c) = G(c)$. Therefore $F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$.

Theorem(3.2): Let $\emptyset \neq A \subseteq X$ and $S, T, h, G: X \to X$ be mappings s.t $a_\circ \in F(S) \cap F(T) \cap F(h) \cap F(G)$ for some $a_\circ \in X, S(\partial A \cap A) \subseteq A$ and $T(\partial A \cap A) \subseteq A$. Assume that $h(p_A(a_\circ)) = G(P_A(a_\circ)) = P_A(a_\circ)$ and the pairs $\{S, h\}$ and $\{T, G\}$ are C_q-commuting and continuous on $P_A(a_\circ)$ and satisfies for all $x \in P_A(a_\circ) \cup \{a_\circ\}$,

$$\|S(a)-T(b)\|_p$$
$$\le \begin{cases} \|h(a)-G(b)\|_p \quad if\ b = a_\circ, \\ max\left\{\begin{matrix}\|h(a)-G(b)\|_p, dist(h(a),[q,S(a)]),\\ dist(G(b),[q,T(b)]), dist(h(a),[q,T(b)]), dist(G(b),[q,S(a)])\end{matrix}\right\} \end{cases} \quad (3\text{-}2)$$

$if\ b \in P_A(a_\circ)$

Suppose that $P_A(a_\circ)$ is closed, has property (a_1). with respect to S and T with $q \in F(h) \cap F(G)$ and h and G has property (a_2). then $P_A(a_\circ) \cap F(S) \cap F(T) \cap F(h) \cap F(G) \neq \emptyset$ if one of the following conditions is satisfied:

i. $Cl\left(S\left(P_A(a_\circ)\right)\right)$ and $Cl\left(T\left(P_A(a_\circ)\right)\right)$ are compact and h and G are continuous.
ii. $P_A(a_\circ)$ is complete, $F(h)$ and $F(G)$ are bounded, and S and T are compact maps.
iii. $P_A(a_\circ)$ is bounded and complete, S and T are hemicompact, and h and G are continuous.
iv. $P_A(a_\circ)$ is weakly compact, X is complete, $h - S$ and $G - T$ are demiclosed at o, h, and G are weakly continuous.
v. X is complete, $P_A(a_\circ)$ is weakly compact, S and T are completely continuous, and h and G are continuous.

Proof: Let $a \in P_A(a_\circ)$, then $\|a - a_\circ\|_p = dist(a_\circ, A)$.
Note that
$0 < k < 1, \|ka_\circ - (1-k)a - a_\circ\|_p = (1-k)^p \|a - a_\circ\|_p < dist(a_\circ, A)$
Hence the line segment $\{ka_\circ - (1-k)a: 0 < k < 1\}$ and the set A are disjoint. Therefore $a \notin int(A)$ and so $a \in \partial A$.
Since $S(\partial A \cap A) \subseteq A$ and $T(\partial A \cap A) \subseteq A$, then $S(a) \in A$ and $T(a) \in A$.
Also, since $h\left(p_A(a_\circ)\right) = G\left(P_A(a_\circ)\right) = P_A(a_\circ)$,
$a_\circ = h(a_\circ) = G(a_\circ) = S(a_\circ) = T(a_\circ)$ and by using condition (3.2), we have
$\|S(a) - a_\circ\|_p = \|S(a) - T(a_\circ)\|_p \leq \|h(a) - G(a_\circ)\|_p \quad = \|h(a) - a_\circ\|_p \quad = dist(a_\circ, A)$
And $\|T(a) - a_\circ\|_p = \|S(a) - T(a_\circ)\|_p \leq \|h(a) - G(a_\circ)\|_p = \|h(a) - a_\circ\|_p \quad = dist(a_\circ, A)$
Therefore $S, T: P_A(a_\circ) \to P_A(a_\circ)$
Since $P_A(a_\circ)$is closed set then $Cl\left(P_A(a_\circ)\right) = P_A(a_\circ)$, and since
$S\left(P_A(a_\circ)\right) \subseteq P_A(a_\circ) = Cl\left(P_A(a_\circ)\right)$, this implies $cl(S(P_A(a_\circ))) \subseteq G\left(P_A(a_\circ)\right)$
In a similar way $cl(T(P_A(a_\circ))) \subseteq h\left(P_A(a_\circ)\right)$, hence the result go ahead of theorem (3.1).

4- Well-posed Problem

Definition (4.1): Let $(X, \| \quad \|_p)$ be a p-normed space and $T: X \longrightarrow X$ a mapping, the f.p problem of T is said to be well-posed if:

i. T has a unique f.p $a_\circ \in X$;
ii. $\forall$ sequence $\{a_n\}$ in X such that $\lim_{n\to\infty} \|T(a_n) - a_n\|_p = 0$, we have $\lim_{n\to\infty} \|a_n - a_\circ\|_p = 0$.

Definition (4.2): Let $(X, \| \quad \|_p)$ be a p-n.s and let $\mathcal{T}$ be a set of mappings in X. The f.p of $\mathcal{T}$ is said to be w-p if:
$\mathcal{T}$ have a unique f.p $a_\circ \in X$;
for any sequence $\{a_n\}$ of in X such that $\lim_{n\to\infty} \|T(a_n) - a_n\|_p = 0, \forall\ T \in \mathcal{T}$ we have $\lim_{n\to\infty} \|a_n - a_\circ\|_p = 0$.

Theorem (4.1): If $X, A, S, T, G, h, Cl\left(S(A)\right), Cl\left(T(A)\right), CL\left(h(A)\right)$ and $Cl\left(G(A)\right)$ as in theorem (2.2), then the c.f.p for the set mappings $\{S, T, h, G\}$ is w-p.

Proof: By theorem (2.2), the mappings $S, T, h,$ and G have a unique c.f.p b such that

$$S(b) = T(b) = h(b) = G(b) = b \tag{4-1}$$

Let $\{a_n\}$ be a sequence in A such that
$\lim_{n\to\infty} \|S(a_n) - a_n)\|_p = \lim_{n\to\infty} \|T(a_n) - a_n)\|_p = \lim_{n\to\infty} \|h(a_n) - a_n)\|_p = \lim_{n\to\infty} \|G(a_n) - a_n)\|_p = 0$
By the triangle inequality, $b = S(b)$,(2.1) and (4.1) having

$$\begin{aligned}
\|b-a_n\|_p &\le \|b-T(a_n)\|_p + \|T(a_n)-a_n\|_p = \|S(b)-T(a_n)\|_p + \|T(a_n)-a_n\|_p \\
&\le k\ max\begin{Bmatrix} \|h(b)-G(a_n)\|_p, \big(h(b),S(b)\big), \\ \|G(a_n)-T(a_n)\|_p, \|h(b)-T(a_n)\|_p, \|G(a_n),S(b)\|_p \end{Bmatrix} \\
&+ \|T(a_n)-a_n\|_p \\
&\le k\ max\begin{Bmatrix} \|h(b)-G(a_n)\|_p, \|h(b)-S(b)\|_p, \\ \|G(a_n)-T(a_n)\|_p, \|h(b)-T(a_n)\|_p, \|G(a_n)-S(b)\|_p \end{Bmatrix} \\
&+ \|T(a_n)-a_n\|_p \\
&= k\ max\{\|b-G(a_n)\|_p, \|G(a_n)-T(a_n)\|_p, \|b-T(a_n)\|_p\} + \|T(a_n)-a_n\|_p \\
&\le k\ max\{\|b-G(a_n)\|_p, \|G(a_n)-b\|_p + \|b-T(a_n)\|_p, \|b\ -T(a_n)\|\} \\
&+ \|T(a_n)-a_n\|_p = k\ \|G(a_n)-b\|_p + k\|b-T(a_n)\|_p + \|T(a_n)-a_n\|_p \\
&\le k\|G(a_n)-a_n\|_p + k\|a_n-b\|_p + k\|b-a_n\|_p + k\|a_n-T(a_n)\|_p \\
&+ \|T(a_n)-a_n\|_p \\
&= k\|G(a_n)-a_n\|_p + 2k\|a_n-b\|_p + (1+k)\|T(a_n)-a_n\|_p\ (1-2k)\|a_n-b\|_p \\
&\le k\|G(a_n)-a_n\|_p + (1+k)\|T(a_n)-a_n\|_p
\end{aligned}$$

Thus we have, $\lim_{n\to\infty}\|a_n-b\|_p = 0$, hence c.f.p for the mappings $\{S,T,h,G\}$ is w-p.

Theorem (4.2): If A, X, S, T, h and G as in theorem (3.1), then the c.f.p for the mappings $\{S,T,h,G\}$ is well posed.

Proof: By theorem (3.1), the mappings $S,T,h,$ and G has a unique common fixed point b.
Let $\{a_n\}$ sequence in A s.t $\lim_{n\to\infty}\|S(a_n)-a_n)\|_p = \lim_{n\to\infty}\|T(a_n)-a_n)\|_p = \lim_{n\to\infty}\|h(a_n)-a_n)\|_p = \lim_{n\to\infty}\|G(a_n)-a_n)\|_p = 0$
By the triangle inequality, $S(b)=b$, (2.2) and (4.1) we have:

$$\begin{aligned}
\|b-a_n\|_p &\le \|b-T(a_n)\|_p + \|T(a_n)-a_n\|_p \|b-a_n\|_p = \|S(b)-T(a_n)\|_p + \|T(a_n)-a_n\|_p \\
&\le k\ max\begin{Bmatrix} \|h(b)-G(a_n)\|_p, dist(h(b),[q,S(b)]), \\ dist(G(a_n),[q,T(a_n)]), dist(h(b),[q,T(a_n)]), dist(G(a_n),[q,S(b)]) \end{Bmatrix} \\
&+ \|T(a_n)-a_n\|_p \\
&\le k\ max\begin{Bmatrix} \|h(b)-G(a_n)\|_p, \|h(b)-S(b)\|_p, \\ \|G(a_n)-T(a_n)\|_p, \|h(b)-T(a_n)\|_p, \|G(a_n)-S(b)\|_p \end{Bmatrix} \\
&+ \|T(a_n)-a_n\|_p \\
&= k\ max\{\|b-G(a_n)\|_p, \|G(a_n)-T(a_n)\|_p, \|b-T(a_n)\|_p\} + \|T(a_n)-a_n\|_p \\
&\le k\ max\{\|b-G(a_n)\|_p, \|G(a_n)-b\|_p + \|b-T(a_n)\|_p, \|b\ -T(a_n)\|\} \\
&+ \|T(a_n)-a_n\|_p = k\ \|G(a_n)-b\|_p + k\|b-T(a_n)\|_p + \|T(a_n)-a_n\|_p \\
&\le k\|G(a_n)-a_n\|_p + k\|a_n-b\|_p + k\|b-a_n\|_p + k\|a_n-T(a_n)\|_p \\
&+ \|T(a_n)-a_n\|_p \\
&= k\|G(a_n)-a_n\|_p + 2k\|a_n-b\|_p + (1+k)\|T(a_n)-a_n\|_p(1-2k)\|a_n-b\|_p \\
&\le k\|G(a_n)-a_n\|_p + (1+k)\|T(a_n)-a_n\|_p
\end{aligned}$$

Thus we have, $\lim_{n\to\infty}\|a_n-b\|_p = 0$, having the c.f.p for the mappings $\{S,T,h,G\}$ is w-p.

A New Algorithm to Estimate the Parameters of Nonlinear Regression

A New Algorithm to Estimate the Parameters of Nonlinear Regression

Zaid Adil Abd alkreem and Bayda Atiya Kalaf

Abstract. The procedures to estimate the parameters are important in many scientific fields that are required to develop mathematical models. Thus, this paper is proposed as a Gravitational Search algorithm for estimating the parameters of nonlinear regression models. Also, a simulation study is conducted to investigate the performance of the proposed methods in this paper. The results show that GSA approach provides accurate estimates and is satisfactory for the parameter estimation of the nonlinear regression models.

1. Introduction

Nonlinear Regression Analysis (NLRA) was one of the most widely used accurate statistical steps that explain the relationship between two variables or more [1]. The common form of a regression model is $y = f(x, \beta) + \varepsilon$. Which y is the dependent variable, *x* is an independent vector variable(s), β is a vector of the parameter (s), and ε is the error factor usually supposed to be uncorrelated with mean zero and constant difference. In the parameter estimation problem, the form of the nonlinear regression function is known but it contains unknown parameters $\beta 1,..., \beta p$.

There are a large number of articles on how to estimates the parameter of nonlinear regression models. Aşıkgil and Erar [2] examined the nonlinear parameter estimation efficiency under the issue of auto reconditioned errors.

The most and commonly used algorithm Gauss-Newton method (also called the Newton-Raphson method) [3]. However, the nonlinearity model produces a hard estimation of parameters and creates a very difficult and challenging statistical analysis of parameter estimates. In addition, it is not considered an easy controlled by practitioners and need much more detailed information to work properly. These difficulties are arising because of an increased number of parameters and the multi-conditioned nature of the function of the objective. Nonlinear regression models. Michailidis[4]considered Jaya's optimization algorithm for estimating nonlinear metaheuristic algorithm named Jaya .then tested it on a set of benchmark regression problems. Tvrd´ık and K˘riv´y [5] used some stochastic algorithms to solve the issue of global optimization of nonlinear regression models. These algorithms were applied to estimate the nonlinear regression model parameters. Tabatabai et al.[6] provided a robust alternative method to the normal Least Squares nonlinear regression method.

In recent decades, the researcher aims to resolve complicated problems by using metaheuristic to overcome drawbacks of classical procedures and have many benefits containing the simplicity of implementation, reliability, robustness, and effectiveness.[7] Adibifard et al.[8] used PSO algorithm to perform nonlinear regression in well test analysis. Root Mean Square Error over pressurized and

pressurized derivative data is employed to determine the formula of cost function f and the multi-objective issue is minimized to a single-objective one by containing the weight for each cost function related to over pressurized and pressurized derivative data. Özsoy, and Örkçü,[9] proposed Particle Swarm Optimization (PSO) algorithm in order to improve the accuracy of parameters estimation for nonlinear regression models. The PSO algorithm is examined on the famous 28 nonlinear regression tasks of various levels of difficulty.

On the other hand, Gravitational Search Algorithm (GSA) is a modern meta-heuristic and population-based search algorithm that depends on gravity Newton's law and motion law. Additionally, GSA has many benefits as, adaptive learning rate, memory-less algorithm and, perfect and rapid convergence. Additionally, GSA has been successfully used in complex problems. Thus, in this paper, Gravitational Search Algorithm was used to estimate the parameters of nonlinear regression models.

The organized paper is, section two provides the Maximum-likelihood Estimation of two nonlinear regression models; Section three describes the procedural Gravitational Search Algorithm; Section four consists of a simulation study; a conclusion is provided in section five.

2. Maximum likelihood Estimation Nonlinear regression models

The Maximum likelihood method (MLE) was used to estimate the parameter for two models of nonlinear regression (Misra 1d, and MGH 09 Model) as follows:

2.1 Maximum likelihood method to solve Misra 1d Model

The Misra 1dmodel is

$$f(x_i;\beta)=\frac{\beta_1\beta_2 x}{1+\beta_2 x} \tag{1}$$

MLE method of estimation depends on maximizing the pdf estimation:

$$L=f(x_1,x_2,\dots\dots,x_n,\beta_i,\sigma^2)$$

$$L=(2\pi\sigma^2)^{-\frac{n}{2}}e^{-\frac{\sum_{i=1}^{n}(y_i-f(x_i;\beta))^2}{2\sigma^2}}$$

$$lnL=-\frac{n}{2}ln2\pi-\frac{n}{2}ln\sigma^2-\frac{\sum_{i=1}^{n}(y_i-f(x_i;\beta))^2}{2\sigma^2}$$

$$lnL=-\frac{n}{2}ln2\pi-\frac{n}{2}ln\sigma^2-\frac{\sum_{i=1}^{n}(y_i-\frac{\beta_1\beta_2 x}{1+\beta_2 x})^2}{2\sigma^2}$$

Numerical procedures as Newton-Raphson was used to estimate the parameters since the equations are complicated to be solved. Therefore, the equation for this method for the first model is as follows

$$\begin{pmatrix}\hat{\beta}_1\\ \hat{\beta}_2\\ \hat{\sigma}^2\end{pmatrix}=\begin{pmatrix}\beta_{10}\\ \beta_{20}\\ \sigma_0^2\end{pmatrix}-\begin{pmatrix}\frac{\partial h_1}{\partial\beta_1} & \frac{\partial h_1}{\partial\beta_2} & \frac{\partial h}{\partial\sigma^2}\\ \frac{\partial h_2}{\partial\beta_1} & \frac{\partial h_2}{\partial\beta_2} & \frac{\partial h_2}{\partial\sigma^2}\\ \frac{\partial h_3}{\partial\beta_1} & \frac{\partial h_3}{\partial\beta_2} & \frac{\partial h_3}{\partial\sigma^2}\end{pmatrix}^{-1}\begin{pmatrix}\frac{\partial lnL}{\partial\beta_1}\\ \frac{\partial lnL}{\partial\beta_2}\\ \frac{\partial lnL}{\partial\sigma^2}\end{pmatrix} \tag{2}$$

$\begin{pmatrix}\beta_{10}\\ \beta_{20}\\ \sigma_0^2\end{pmatrix}$ Represents the vector of the initial parameters

$$h_1 = \frac{\partial lnL}{\partial \beta_1} = \frac{1}{\sigma^2}[\sum_{i=1}^{n}\left(\frac{y_i \beta_2 x}{1+\beta_2 x}\right) - \sum_{i=1}^{n}(\frac{\beta_1 \beta_2^2 x^2}{(1+\beta_2 x)^2})]$$

$$h_2 = \frac{\partial lnL}{\partial \beta_2} = \frac{1}{\sigma^2}[\sum_{i=1}^{n}\left(\frac{y_i \beta_1 x}{(1+\beta_2 x)^2}\right) - \sum_{i=1}^{n}(\frac{\beta_1^2 \beta_2 x^2}{(1+\beta_2 x)^3})]$$

$$h_3 = \frac{\partial lnL}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \sum_{i=1}^{n}\frac{1}{2\sigma^4}(y_i - \frac{\beta_1 \beta_2 x}{1+\beta_2 x})^2$$

$$\frac{\partial h_1}{\partial \beta_1} = -\frac{1}{\sigma^2}\sum_{i=1}^{n}(\frac{\beta_2^2 x^2}{(1+\beta_2 x)^2})$$

$$\frac{\partial h_1}{\partial \beta_2} = (\sum_{i=1}^{n}\frac{y_i x}{\sigma^2(1+\beta_2 x)^2} - \sum_{i=1}^{n}\frac{2\beta_1 \beta_2 x^2}{\sigma^2(1+\beta_2 x)^3})$$

$$\frac{\partial h_1}{\partial \sigma^2} = -\frac{1}{\sigma^4}(\sum_{i=1}^{n}\frac{y_i \beta_2 x}{1+\beta_2 x} - \sum_{i=1}^{n}\frac{\beta_1 \beta_2^2 x^2}{(1+\beta_2 x)^3})$$

$$\frac{\partial h_2}{\partial \beta_1} = \sum_{i=1}^{n}\frac{y_i x}{\sigma^2(1+\beta_2 x)^2} - \sum_{i=1}^{n}\frac{2\beta_1 \beta_2 x^2}{\sigma^2(1+\beta_2 x)^3}$$

$$\frac{\partial h_2}{\partial \beta_2} = \sum_{i=1}^{n}\frac{-2y_i \beta_1 x^2}{\sigma^2(1+\beta_2 x)^3} - \sum_{i=1}^{n}\frac{\beta_1^2 x^2(1-2\beta_2 x)}{\sigma^2(1+\beta_2 x)^4}$$

$$\frac{\partial h_2}{\partial \sigma^2} = \frac{1}{\sigma^4}\left[\sum_{i=1}^{n}(\frac{y_i \beta_1 x}{(1+\beta_2 x)^2}\right) - \sum_{i=1}^{n}\left(\frac{\beta_1^2 \beta_2 x^2}{(1+\beta_2 x)^3}\right)]$$

$$\frac{\partial h_3}{\partial \beta_1} = -\frac{1}{\sigma^4}\left[\sum_{i=1}^{n}(\frac{y_i \beta_2 x}{1+\beta_2 x}\right) - \sum_{i=1}^{n}\left(\frac{\beta_1 \beta_2^2 x^2}{(1+\beta_2 x)^2}\right)]$$

$$\frac{\partial h_3}{\partial \beta_2} = -\frac{1}{\sigma^4}\left[\sum_{i=1}^{n}(\frac{y_i \beta_1 x}{(1+\beta_2 x)^2}\right) - \sum_{i=1}^{n}\left(\frac{\beta_1^2 \beta_2 x^2}{(1+\beta_2 x)^3}\right)]$$

$$\frac{\partial h_3}{\partial \sigma^2} = \frac{n}{2\sigma^4} - \sum_{i=1}^{n}\frac{1}{\sigma^6}(y_i - \frac{\beta_1 \beta_2 x}{1+\beta_2 x})^2$$

2.2 Maximum likelihood method to solve MGH 09 Model

The MGH 09 Model is

$$f(x_i, \beta) = \frac{\beta_1(x^2 + x\beta_2)}{x^2 + x\beta_3 + \beta_4} \tag{3}$$

The formula for MLE is for MGH 09 Model;

$$\text{lnL} = -\frac{n}{2}ln2\pi - \frac{n}{2}ln\sigma^2 - \frac{\sum_{i=1}^{n}\left(y_i - \frac{\beta_1(x^2 + x\beta_2)}{x^2 + x\beta_3 + \beta_4}\right)^2}{2\sigma^2}$$

Thus, the following equation matrixes are applied to estimate the parameters for the non-linear regression model by using the Newton-Raphson method for the second model.

$$\begin{pmatrix}\hat{\beta}_1\\ \hat{\beta}_l\\ \hat{\beta}_3\\ \hat{\beta}_4\\ \hat{\sigma}^2\end{pmatrix}=\begin{pmatrix}\beta_{10}\\ \beta_{20}\\ \beta_{30}\\ \beta_{40}\\ \sigma_0^2\end{pmatrix}-\begin{pmatrix}\frac{\partial h_1\partial h_1\partial h_1\partial h_1}{\partial\beta_1\partial\beta_2\partial\beta_3\partial\beta_4}\frac{\partial h_1}{\partial\sigma^2}\\ \frac{\partial h_2\partial h_2\partial h_2\partial h_2}{\partial\beta_1\partial\beta_2\partial\beta_3\partial\beta_4}\frac{\partial h_2}{\partial\sigma^2}\\ \frac{\partial h_3\partial h_3\partial h_3\partial h_3}{\partial\beta_1\partial\beta_2\partial\beta_3\partial\beta_4}\frac{\partial h_3}{\partial\sigma^2}\\ \frac{\partial h_4\partial h_4\partial h_4\partial h_4}{\partial\beta_1\partial\beta_2\partial\beta_3\partial\beta_4}\frac{\partial h_4}{\partial\sigma^2}\\ \frac{\partial h_5\partial h_5\partial h_5\partial h_5}{\partial\beta_1\partial\beta_2\partial\beta_3\partial\beta_4}\frac{\partial h_5}{\partial\sigma^2}\end{pmatrix}^{-1}\begin{pmatrix}\frac{\partial lnL}{\partial\beta_1}\\ \frac{\partial lnL}{\partial\beta_2}\\ \frac{\partial lnL}{\partial\beta_3}\\ \frac{\partial lnL}{\partial\beta_4}\\ \frac{\partial lnL}{\partial\sigma^2}\end{pmatrix}$$

$\begin{pmatrix}\beta_{10}\\ \beta_{20}\\ \beta_{30}\\ \beta_{40}\\ \sigma_0^2\end{pmatrix}$ Represents the vector of the initial parameters.

$$h_1=\frac{\partial lnL}{\partial\beta_1}=\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i(x^2+x\beta_2)}{x^2+x\beta_3+\beta_4}-\frac{\beta_1(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$h_2=\frac{\partial lnL}{\partial\beta_2}=\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i\beta_1 x}{x^2+x\beta_3+\beta_4}-\frac{\beta_1^2(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$h_3=\frac{\partial lnL}{\partial\beta_3}=-\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i\beta_1 x(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}-\frac{\beta_1^2 x(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^3}\right)$$

$$h_4=\frac{\partial lnL}{\partial\beta_4}=-\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i\beta_1(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}-\frac{\beta_1^2(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^3}\right)$$

$$h_5=\frac{\partial lnL}{\partial\sigma^2}=-\frac{n}{2\sigma^2}+\frac{1}{2\sigma^4}\sum_{i=1}^{n}\left(y_i-\frac{\beta_1(x^2+x\beta_2)}{x^2+x\beta_3+\beta_4}\right)^2$$

$$\frac{\partial h_1}{\partial\beta_1}=-\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$\frac{\partial h_1}{\partial\beta_2}=\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i x}{x^2+x\beta_3+\beta_4}-\frac{2\beta_1 x(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$\frac{\partial h_1}{\partial\beta_3}=-\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i x(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}-\frac{2\beta_1 x(x^2+x\beta_2)^2(x^2+x\beta_3+\beta_4)}{(x^2+xB_3+B_4)^4}\right)$$

$$\frac{\partial h_1}{\partial\beta_4}=-\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}-\frac{2\beta_1(x^2+x\beta_2)^2(x^2+x\beta_3+\beta_4)}{(x^2+x\beta_3+\beta_4)^4}\right)$$

$$\frac{\partial h_1}{\partial\sigma^2}=-\frac{1}{\sigma^4}\sum_{i=1}^{n}\left(\frac{y_i(x^2+x\beta_2)}{x^2+x\beta_3+\beta_4}-\frac{\beta_1(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$\frac{\partial h_2}{\partial\beta_1}=\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i x}{x^2+x\beta_3+\beta_4}-\frac{2\beta_1 x(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$\frac{\partial h_2}{\partial\beta_2}=-\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{\beta_1^2 x^2}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$\frac{\partial h_2}{\partial \beta_3} = -\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i\beta_1 x^2}{(x^2+x\beta_3+\beta_4)^2} - \frac{2\beta_1^2 x^2(x^2+x\beta_2)^2(x^2+x\beta_3+\beta_4)}{(x^2+x\beta_3+\beta_4)^4}\right)$$

$$\frac{\partial h_2}{\partial \beta_4} = -\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i\beta_1 x}{(x^2+x\beta_3+\beta_4)^2} - \frac{2\beta_1^2 x(x^2+x\beta_2)^2(x^2+x\beta_3+\beta_4)}{(x^2+x\beta_3+\beta_4)^4}\right)$$

$$\frac{\partial h_2}{\partial \sigma^2} = -\frac{1}{\sigma^4}\sum_{i=1}^{n}\left(\frac{y_i\beta_1 x}{x^2+x\beta_3+\beta_4} - \frac{\beta_1^2 x(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2}\right)$$

$$\frac{\partial h_3}{\partial \beta_1} = -\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i x(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^2} - \frac{2\beta_1(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^3}\right)$$

$$\frac{\partial h_3}{\partial \beta_2} = -\frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{y_i\beta_1 x^2}{(x^2+xB_3+B_4)^2} - \frac{2\beta_1^2 x^2(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^3}\right)$$

$$\frac{\partial h_3}{\partial \beta_3} = \frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{2y_i\beta_1 x^2(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)^3} - \frac{3\beta_1^2 x^2(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^4}\right)$$

$$\frac{\partial h_3}{\partial \beta_4} = \frac{1}{\sigma^2}\sum_{i=1}^{n}\left(\frac{2y_i\beta_1 x(x^2+x\beta_2)}{(x^2+xB_3+B_4)^3} - \frac{3\beta_1^2 x(x^2+x\beta_2)^2}{(x^2+x\beta_3+\beta_4)^4}\right)$$

$$\frac{\partial h_5}{\partial \sigma^2} = \frac{n}{2\sigma^4} - \frac{1}{\sigma^6}\sum_{i=1}^{n}\left(y_i - \frac{\beta_1(x^2+x\beta_2)}{(x^2+x\beta_3+\beta_4)}\right)^2$$

3. Gravitational Search Algorithm Technique

In 2009, Rashedi et al. [10] introduced the Gravitational Search Algorithm (GSA) for solving optimization problems. The populace-established heuristic algorithm is founded on the mass interactions and gravity law. The solutions in the population of GSA are called agents, through the gravity force the agents interact with each other. In the population, measured the performance of each agent by its mass. The best solution is the solution with a heavier mass.
The objects masses are obeying of gravity low as following

$$\mathrm{F_{ij}} = \mathrm{G}\frac{M_{aj} \times \mathrm{M_{pj}}}{\mathrm{R}^2} \tag{4}$$

Where G is gravitational constant,$\mathrm{M_{pj}}$ is the mass of the second object, $M_{aj}$is the mass of the first object ,F is a magnitude of the gravitational force, and R is the distance between the two objects M_{aj}, $\mathrm{M_{pj}}$.

$$\mathrm{a_i} = \frac{\mathrm{F_{ij}}}{\mathrm{M_{ij}}} \tag{5}$$

The velocities and positions will be updated by agents during the search, as shown in Equations 6, 7 respectively.

$$\mathrm{V_i(t+1)} = \mathrm{rand_i} \times \mathrm{V_i(t+1)} + \mathrm{a_i(t)} \tag{6}$$
$$\mathrm{X_i(t+1)} = \mathrm{rand_i} \times \mathrm{v_i(t+1)} + \mathrm{a_i(t)} \tag{7}$$

The following steps of the GSA can be summarized as below:
Step 1. initializes values of gravitational constant G_0, α, ε, and the iteration counter t.
Step 2. generated the initial population randomly and consists of N agents, the position defined for each agent as below:

$$\mathrm{x_i(t)} = \left(\mathrm{x_i^1(t), x_i^2(t), \dots\dots\dots x_i^n(t)}\right) \quad \mathrm{i} = 1,2,\dots\dots\dots \mathrm{N}$$

Step 3. This step is replicated until satisfied with termination criteria¬
A. assigned the best, worst agents and evaluated the population for all agents
B. the constant of gravitational is updated as Equation 4
C. calculates the force as follows:

$$\mathrm{F_i^j(t)} = \mathrm{G(t)}\frac{M_{aj}(\mathrm{t}) \times \mathrm{M_{pj}(t)}}{\mathrm{R_{ij}(t)} + \in}\left(X_j^d(t) - X_i^d(t)\right) \tag{8}$$

WhereM_{aj} is the active gravitational mass of agent j ,$\mathrm{M_{pj}}$ is the passive gravitational mass of agent i ,G(t) is gravitational constant at time t.
D. At iteration t, calculate the total force acting on agent i as follows:

$$F_i^d(t) = \sum_{j \in Kbest\,, j \neq i} rand_j F_{ij}^d(t) \tag{9}$$

Where K best is the set of first K agents with the best fitness value and biggest mass
E. Calculate the inertial mass as following

$$m_i(t) = \frac{fit_i - worst(t)}{best(t) - worst(t)} \quad (10)$$

$$\mathrm{M_i(t)} = \frac{\mathrm{m_i(t)}}{\sum_{\mathrm{j=1}}^{\mathrm{N}} \mathrm{m_j(t)}} \quad (11)$$

F. Calculated the agent of acceleration as following:

$$\mathrm{a_i(t)} = \frac{\mathrm{F_i(t)}}{\mathrm{M_{ii}(t)}} \quad (12)$$

G. The position and velocity of agent i are computed as shown in Equations 6, 7 .
H. The iteration counter is increased until termination criteria satisfied
Step 4. The best optimal solution is produced.
The log-likelihood function was used as a fitness function of the GSA.

4. Graph Simulation study

In order to verify the performance of the different estimator's methods, Simulation was used based on Mean Squares Error (MSE) to estimate the parameters of two models for nonlinear regression (Misra 1d and MGH 09 Model). Calculate the values of response variable yi depend on x_i were generated according to the exponential distribution$(exp(2))$, while the random variableei is generated according to $N(0, \sigma^2)$.In addition, each simulation condition was generated by 1000 replications. Various sample sizes are tested: 20, 40, 80,160, and 200. The simulation program was written using Matlab 2013. Generate the initial value of parameters for each model's different set parameters utilized for each model as: $(\beta_1, \beta_2) = (1000, 200)$, and (500, 500) for the first model, while for the second model $(\beta_1, \beta_2, \beta_3, \beta_2)$ = (0.3 , 0.2, 0.1, 0.1) and (0.3, 0.2, 0.3 ,0.4), respectively.
Tables (1- 4) illustrated the results of the estimate parameters and the MSE for each parameter for two models of NLRA. The GSA algorithm provides a better result than MLE method.

Conclusion

In this study, a metaheuristic algorithm (Gravitational Search algorithm) was used as an alternative method to estimate the parameters of two models of nonlinear regression (Misra 1d and Myer 7). To improve the validation of the algorithm, a simulation study was used. The result showed that the Gravitational Search algorithm provides good results than the classical MLE estimator.

Soft Np-Open Sets in Soft Toplogical Spaces

Soft Np-Open Sets in Soft Toplogical Spaces

Sabeha I and Haider Jebur Ali

Department of Mathematics, College of Science, Mustansiriyah University, Baghdad, Iraq

E-mail: ssabihaa@uomustansiriyah.edu.iq

Abstract. This article is devoted to introduce and study a new kind of soft sets in soft topological spaces called soft Np-open sets as a generalization of soft p-open sets. Also, we investigate and prove some of their properties. By using this new soft set we define and study new soft spaces called soft Np-compact spaces, soft Np-Lindelöf spaces, and obtain some of their characterizations and properties. Finally, we discuss the relationships among soft Np-compact spaces, soft Np-Lindelöf spaces, soft p-compact spaces, soft p-Lindelöf spaces, soft compact spaces, and soft Lindelöf spaces.

1. Introduction

Molodtsov [1] proposed the soft set theory as a new mathematical tool for dealing with uncertain objects. Shabir and Naz [2] defined the concept of soft topological spaces by using soft open sets. Aygunuglu and Aygun [3], Rong [4] and AL-Shami and EL-Shafei [5] defined and studied soft compact spaces, soft Lindelöf spaces, soft p-compact spaces, and soft p-Lindelöf spaces resp. Arockiarani and Arokia Lancy [6], Chen [7], Akdag, and Ozkan [8], and Mahmood [9] introduced and investigated soft p-open sets, soft s-open sets, soft α-open sets, and soft N-open sets resp. In the present paper, we define and study the notion of soft Np-open sets as a generalization of soft p-open sets and investigate some of their basic properties. Moreover, we use these soft sets to introduce new kinds of soft spaces called soft Np-compact spaces and soft Np-Lindelöf spaces. The fundamental properties and characterizations of these soft spaces also have been studied.

2. Preliminaries

Definition 2.1: [1]: A pair (H, S) is called a soft set over D, where H is a function of a parameters set S into 2^D. The soft set (H, S) can be written as follows:
$(H, S) = \{(s, H(s)): s \in S \text{ and } H(S) \in 2^D\}$.

Definition 2.2: [10]: The soft union of two soft sets (H_1, S_1) and (H_2, S_2) over a common universe D is the soft set (H, S), where $S = S_1 \cup S_2$, and $\forall\, s \in S$,

$$H(s) = \begin{cases} H_1(s) & \text{if } s \in S_1 - S_2 \\ H_2(s) & \text{if } s \in S_2 - S_1 \\ H_1(s) \cup H_2(s) & \text{if } s \in S_1 \cap S_2 \end{cases}$$

We write $(H, S) = (H_1, S_1) \widetilde{\cup} (H_2, S_2)$.

Definition 2.3: [11]: The soft intersection of two soft sets (H_1, S_1) and (H_2, S_2) over a common universe D is the soft set (H, S), where $S = S_1 \cap S_2$, and $\forall\, s \in S$, $H(s) = H_1(s) \cap H_2(s)$. We write

$(H, S) = (H_1, S_1)\widetilde{\cap}(H_2, S_2)$.

Definition 2.4: [12]: The soft difference of two soft sets (H_1, S_1) and (H_2, S_2) over a common universe D is the soft set (H, S), where $S = S_1 \cap S_2$, and $\forall\, s \in S$, $H(s) = H_1(s) - H_2(s)$. We write $(H, S) = (H_1, S_1) - (H_2, S_2)$.

Definition 2.5: [12]: The soft complement of a soft set (H, S) is denoted by $(H, S)^c$ and is defined by $(H, S)^c = (H^c, S)$, where $H^c: S \to p(D)$ is a function given by $H^c(s) = D - H(s)$, $\forall s \in S$. Clearly, $\widetilde{D}^c = \widetilde{\emptyset}$ and $\widetilde{\emptyset}^c = \widetilde{D}$.

Definition 2.6: [2]: Let $\tilde{\sigma}$ be a family of soft sets over D with a fixed set of parameters S. Then $\tilde{\sigma}$ is called a soft topology on D if:
(i) $\widetilde{\emptyset}$ and $\widetilde{D}$ are members of $\tilde{\sigma}$.
(ii) If $(H_1, S), (H_2, S) \,\widetilde{\in}\, \tilde{\sigma}$, then $(H_1, S)\widetilde{\cap}(H_2, S) \,\widetilde{\in}\, \tilde{\sigma}$.
(iii) If $(H_\alpha, S) \,\widetilde{\in}\, \tilde{\sigma}$, $\forall\, \alpha \in \Omega$, then $\widetilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\} \,\widetilde{\in}\, \tilde{\sigma}$.
The triple $(D, \tilde{\sigma}, S)$ is called a soft topological space (briefly S. T. S.). Every soft set in $\tilde{\sigma}$ is called soft open over D and its complement is called soft closed over D.

Definition 2.7: [2]: Let $(D, \tilde{\sigma}, S)$ be a S. T. S. and $(H, S) \,\widetilde{\subseteq}\, \widetilde{D}$. The soft closure of (H, S), denoted by $cl(H, S)$ is the soft intersection of all soft closed sets in $\widetilde{D}$ which contains (H, S).

Definition 2.8: [13]: Let $(D, \tilde{\sigma}, S)$ be a S. T. S. and $\widetilde{\emptyset} \neq (M, S) \,\widetilde{\subseteq}\, \widetilde{D}$. Then $\tilde{\sigma}_{(M,S)} = \{(W, S)\widetilde{\cap}(M, S): (W, S) \,\widetilde{\in}\, \tilde{\sigma}\}$ is said to be the relative soft topology on (M, S) and $((M, S), \tilde{\sigma}_{(M,S)}, S)$ is said to be a soft subspace of $(D, \tilde{\sigma}, S)$.

Definition 2.9: [14]: A soft set (H, S) over D is called a soft point denoted by $\tilde{x} = (s, \{x\})$ if there is $s \in S$ and $x \in D$ such that $H(s) = \{x\}$ and $H(t) = \emptyset$ for each $t \in S\backslash\{s\}$.

Definition 2.10: [14]: A soft set (H, S) over D is called finite if $H(s)$ is finite for each $s \in S$.

Definition 2.11: A soft subset (H, S) of $(D, \tilde{\sigma}, S)$ is called:
(i) Soft pre-open (briefly soft $p-$ open) [6] if $(H, S) \,\widetilde{\subseteq}\, int(cl(H, S))$.
(ii) Soft semi open (briefly soft $s-$ open) [7] if $(H, S) \,\widetilde{\subseteq}\, cl(int(H, S))$.
(iii) Soft $\alpha-$ open [8] if $(H, S) \,\widetilde{\subseteq}\, int(cl(int(H, S)))$.
(iv) Soft $N-$ open [9] if for each $\tilde{x} \,\widetilde{\in}\, (H, S)$, there exists a soft open set (W, S) containing $\tilde{x}$ such that $(W, S) - (H, S)$ is a finite soft set.

Definition 2.12: [5]: A soft subset (H, S) of $(D, \tilde{\sigma}, S)$ is called soft pre-clopen (briefly soft $p-$ clopen if it is soft $p-$ open and soft $p-$ closed.

Proposition 2.13: [15],[5],[16]: Let $(D, \tilde{\sigma}, S)$ be a S. T. S. Then:

i. If (A, S) is soft $p-$ open in $\widetilde{D}$ and (B, S) is soft open in $\widetilde{D}$, then $(A, S)\widetilde{\cap}(B, S)$ is soft $p-$ open in $\widetilde{D}$.
ii. If (T, S) is soft $p-$ open in $\widetilde{D}$ and (H, S) is soft $s-$ open in $\widetilde{D}$, then $(H, S)\widetilde{\cap}(T, S)$ is soft $p-$ open in $((T, S), \tilde{\sigma}_{(T,S)}, S)$.
iii. If $(B, \tilde{\sigma}_B, S)$ is a soft p-open subspace of $(D, \tilde{\sigma}, S)$ and $(H, S) \,\widetilde{\subseteq}\, \widetilde{B} \,\widetilde{\subseteq}\, \widetilde{D}$. Then (H, S) is soft $p-$ open in $\widetilde{D} \iff$ it is soft $p-$ open in $\widetilde{B}$.

Definition 2.14: [4],[5]: A S. T. S. $(D, \tilde{\sigma}, S)$ is called soft p-compact (resp. soft $p-$ Lindelöf) if all soft $p-$ open cover of $\tilde{D}$ has a finite (countable) subcover.

Definition 2.15: [17]: A S. T. S. $(D, \tilde{\sigma}, S)$ is called a soft $\tilde{T}_1$-space if for any two distinct soft points $\tilde{x}$ and $\tilde{y}$ of $\tilde{D}$, there are two soft open sets (H_1, S) and (H_2, S) in $\tilde{D}$ such that $\tilde{x} \tilde{\in} (H_1, S)$, $\tilde{y} \tilde{\notin} (H_1, S)$ and $\tilde{y} \tilde{\in} (H_2, S)$, $\tilde{x} \tilde{\notin} (H_2, S)$.

3. Soft Np-Open Sets

Definition 3.1: A soft set (A, S) in a S. T . S. $(D, \tilde{\sigma}, S)$ is called soft N-pre-open (briefly soft Np-open) if $\forall\, \tilde{u} \tilde{\in} (A, S), \exists$ a soft $p-$ open set (O, S) in $\tilde{D}$ containing $\tilde{u}$ such that $(O, S) - (A, S)$ is a finite soft set. The collection of all soft Np-open sets in $(D, \tilde{\sigma}, S)$ is denoted by $\tilde{\sigma}_{Np}$.

Proposition 3.2: In a S. T. S. $(D, \tilde{\sigma}, S)$ the following statements are satisfied:

i. Every soft open set is soft $Np-$ open.
ii. Every soft $N-$ open set is soft $Np-$ open.
iii. Every soft $p-$ open set is soft $Np-$ open.

The following examples show that the converse of (i),(ii), and (iii) in the above Proposition are not true.

Example 3.3: Let $D = \{a, c, b\}$, $S = \{s_1, s_2, s_3\}$, and let $\tilde{\sigma} = \{\tilde{D}, \tilde{\emptyset}, (U, S), (V, S)\}$ be a soft topology over D, where

$$(U, S) = \{(s_1, \{a, c\}), (s_2, \{c, b\}), (s_3, \{a\})\}$$
$$(V, S) = \{(s_1, \{c\}), (s_2, \{b\}), (s_3, \{a\})\}$$

Then $\{(s_1, \{c, b\}), (s_2, \{a, b\}), (s_3, \{a, c\})\}$ is soft $Np-$ open but is not soft open.

Example 3.4: Let $D = \Re$ (the set of real numbers), $S = \{s_1, s_2\}$, and let $\tilde{\sigma} = \{\tilde{\Re}, \tilde{\emptyset}, (K, S)\}$ be a soft topology over $\Re$ where $(K, S) = \{(s_1, \{1\}), (s_2, \{1\})\}$. Then $(N, S) = \{(s_1, \{1,2\}), (s_2, \{1,3\})\}$ is soft $Np-$ open, but is not soft $N-$ open.

Example 3.5: Let $D = \{a, b, c\}$, $S = \{s_1, s_2\}$, and let $\tilde{\sigma} = \{\tilde{D}, \tilde{\emptyset}, (T, S)\}$ be a soft topology over D, where $(T, S) = \{(s_1, \{c\}), (s_2, \{c\})\}$. Then $(N, S) = \{(s_1, \{a, b\}), (s_2, \{b, a\})\}$ is soft $Np-$ open, but is not soft $p-$ open.

From above we get the following diagram.

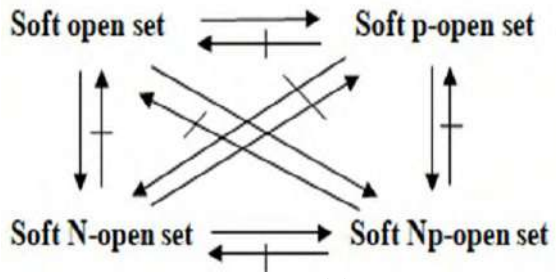

Diagram (1)

Remark 3.6: If (U, S) and (V, S) are soft $Np-$ open sets in $(D, \tilde{\sigma}, S)$, then $(U, S) \tilde{\cap} (V, S)$ may not be soft $Np-$ open.

Example 3.7: Let $D = \Re$, $S = \{s_1, s_2\}$, and let $\tilde{\sigma} = \{(W, S) \tilde{\subseteq} \tilde{\Re}: (W, S)^c \text{ is a finite soft set}\} \tilde{\cup} \{\tilde{\emptyset}\}$ be the soft cofinite topology over $\Re$. Then $(U, S) = \{(s_1, [1,8]), (s_2, [3,8])\}$ and $(V, S) = \{(s_1, [8,11]), (s_2, [8,9])\}$ are soft Np-open sets, but $(U, S) \tilde{\cap} (V, S) = \{(s_1, \{8\}), (s_2, \{8\})$ is not soft Np-open.

Proposition 3.8: If $\{(H_\alpha, S): \alpha \in \Omega\}$ is a family of soft Np-open subsets of $(D, \tilde{\sigma}, S)$. Then $\tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\}$ is soft Np-open in $\tilde{D}$.

Proof: Let $\{(H_\alpha, S): \alpha \in \Omega\}$ be a collection of soft Np-open sets. Now, if $\tilde{a} \tilde{\in} \tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\}$, then $\tilde{a} \tilde{\in} (H_{\alpha_0}, S)$ for some $\alpha_0 \in \Omega$. But $(H_{\alpha_0}, S) \tilde{\in} \tilde{\sigma}_{Np}$, so $\exists$ a soft $p-$open set (O, S) in $\tilde{D}$ containing $\tilde{a}$ such that $(O, S) - (H_{\alpha_0}, S)$ is a finite soft set. Since $(H_{\alpha_0}, S) \tilde{\subseteq} \tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\}$, then $\tilde{D} - \tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\} \tilde{\subseteq} \tilde{D} - (H_{\alpha_0}, S)$. Therefore
$(O, S)\tilde{\cap}(\tilde{D} - \tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\} \tilde{\subseteq} (O, S)\tilde{\cap}(\tilde{D} - (H_{\alpha_0}, S))$.
Hence, $(O, S) - \tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\} \tilde{\subseteq} (O, S) - (H_{\alpha_0}, S))$, that is $(O, S) - \tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\}$ is a finite soft set. Therefore, $\tilde{\cup}\{(H_\alpha, S): \alpha \in \Omega\} \tilde{\in} \tilde{\sigma}_{Np}$.

Corollary 3.9: If $\{(F_\alpha, S): \alpha \in \Omega\}$ is a family of soft Np-closed subsets of $(D, \tilde{\sigma}, S)$, then $\tilde{\cap}\{(F_\alpha, S): \alpha \in \Omega\}$ is soft Np-closed in $\tilde{D}$.

Proof: It is obvious.

Definition 3.10: [15]: A soft subset (L, S) of $(D, \tilde{\sigma}, S)$ is called soft dense if $cl(L, S) = \tilde{D}$.

Definition 3.11: [15]: A S. T. S. $(D, \tilde{\sigma}, S)$ is called soft submaximal if all soft dense set in $\tilde{D}$ is soft open.

Proposition 3.12: [15]: A S. T. S. $(D, \tilde{\sigma}, S)$ is soft submaximal if and only if all soft $p-$open set in $(D, \tilde{\sigma}, S)$ is soft open.

Theorem 3.13: If $(D, \tilde{\sigma}, S)$ is a soft submaximal. Then $(D, \tilde{\sigma}_{Np}, S)$ is a S. T. S.
Proof:

i. Since $\tilde{\emptyset}, \tilde{D} \tilde{\in} \tilde{\sigma}$, then $\tilde{\emptyset}, \tilde{D} \tilde{\in} \tilde{\sigma}_{Np}$.
ii. Let $(L_1, S), (L_2, S) \tilde{\in} \tilde{\sigma}_{Np}$ and $\tilde{x} \tilde{\in} (L_1, S)\tilde{\cap}(L_2, S)$. Then there exists soft p-open subsets (W_1, S) and (W_2, S) of $\tilde{D}$ containing $\tilde{x}$ such that $(W_1, S) - (L_1, S)$ and $(W_2, S) - (L_2, S)$ are finite soft sets. Since $(D, \tilde{\sigma}, S)$ is soft submaximal, then by Proposition (2.12), $(W_1, S)\tilde{\cap}(W_2, S)$ is soft p-open such that $\tilde{x} \tilde{\in} (W_1, S)\tilde{\cap}(W_2, S)$. To show that $((W_1, S)\tilde{\cap}(W_2, S)) - ((L_1, S)\tilde{\cap}(L_2, S))$ is a finite soft set. Observe that

$$\begin{aligned}
&((W_1, S)\tilde{\cap}(W_2, S)) - ((L_1, S)\tilde{\cap}(L_2, S)) \\
&= ((W_1, S)\tilde{\cap}(W_2, S))\tilde{\cap}((L_1, S)\tilde{\cap}(L_2, S))^c \\
&= ((W_1, S)\tilde{\cap}(W_2, S))\tilde{\cap}((L_1, S)^c\tilde{\cup}(L_2, S)^c)) \\
&= [((W_1, S)\tilde{\cap}(W_2, S))\tilde{\cap}(L_1, S)^c]\tilde{\cup}[(W_1, S)\tilde{\cap}(W_2, S))\tilde{\cap}(L_2, S)^c] \\
&\tilde{\subseteq} [(W_1, S)\tilde{\cap}(L_1, S)^c]\tilde{\cup}[(W_2, S))\tilde{\cap}(L_2, S)^c] \\
&= [(W_1, S) - (L_1, S)]\tilde{\cup}[(W_2, S) - (L_2, S)]
\end{aligned}$$

But $(W_1, S) - (L_1, S)$ and $(W_2, S) - (L_2, S)$ are finite soft sets, then so is $((W_1, S)\tilde{\cap}(W_2, S)) - ((L_1, S)\tilde{\cap}(L_2, S))$. Hence $(L_1, S)\tilde{\cap}(L_2, S) \tilde{\in} \tilde{\sigma}_{Np}$.
iii. Let $\{(E_\alpha, S): \alpha \in \Omega\}$ be any family of soft Np-open subsets of $\tilde{D}$. Then by Proposition (2.8), $\tilde{\cup}\{(E_\alpha, S): \alpha \in \Omega\} \tilde{\in} \tilde{\sigma}_{Np}$.

Remark 3.14: The convers of Theorem (2.13) may not be true.

Example 3.15: Let $D = \{a, b, c\}$, $S = \{s_1, s_2, s_3\}$, and let $\tilde{\sigma} = \{\tilde{D}, \tilde{\emptyset}, (G_1, S), (G_2, S)\}$ be a soft topology over D, where $(G_1, S) = \{(s_1, \{a, b\}), (s_2, \{a, c\}), (s_3, \{a, b, c\})\}$ and $(G_2, S) = \{(s_1, \{a, b\}), (s_2, \{c\}), (s_3, \{a, c\})\}$. Then $(D, \tilde{\sigma}_{Np}, S)$ is a soft topological space, but $(D, \tilde{\sigma}, S)$ is not soft submaximal.

Now, we need the following Lemma.

Lemma 3.16: If (B, S) is soft $p-$open and (E, S) is soft $\alpha-$open in $(D, \tilde{\sigma}, S)$, then $(E, S)\tilde{\cap}(B, S)$ is soft $p-$open.

Proof: Since (E, S) is soft $\alpha-$open and (B, S) is soft $p-$open in $\tilde{D}$, then

$$\begin{aligned}(E, S)\tilde{\cap}(B, S) &\tilde{\subseteq} \text{int}(\text{cl}(\text{int}(E, S)))\tilde{\cap}\ \text{int}(\text{cl}(B, S)) \\ &= \text{int}[\text{cl}(\text{int}(E, S))\tilde{\cap}\ \text{int}(\text{cl}(B, S))] \\ &\tilde{\subseteq} \text{int}[\text{cl}[\text{int}(E, S)\tilde{\cap}\ \text{int}(\text{cl}(B, S))]] \\ &\tilde{\subseteq} \text{int}[\text{cl}[\text{int}(E, S)\tilde{\cap}\ \text{cl}(B, S)]] \\ &\tilde{\subseteq} \text{int}[\text{cl}[\text{cl}[\text{int}(E, S))\tilde{\cap}\ (B, S)]]] \\ &= \text{int}[\text{cl}[\text{int}(E, S))\tilde{\cap}\ (B, S)]] \\ &\tilde{\subseteq} \text{int}[\text{cl}[(E, S))\tilde{\cap}\ (B, S)]]\end{aligned}$$

Hence $(E, S)\tilde{\cap}(B, S)$ is soft $p-$open.

Proposition 3.17: Let $(D, \tilde{\sigma}, S)$ be a S. T. S., then:

i. If (G, S) is soft open (resp. soft $\alpha-$open, soft $N-$open) in $\tilde{D}$ and (H, S) is soft $Np-$open in $\tilde{D}$. Then $(G, S)\tilde{\cap}(H, S)$ is soft $Np-$open.
ii. If (P, S) is soft Np-open in $\tilde{D}$ and (T, S) is soft s-open in $\tilde{D}$, then $(P, S)\tilde{\cap}(T, S)$ is soft Np-open in $((T, S), \tilde{\sigma}_{(T,S)}, S)$.
iii. If (P, S) is soft Np-open in $((T, S), \tilde{\sigma}_{(T,S)}, S)$ and (T, S) is soft p-open in $(D, \tilde{\sigma}, S)$, then (P, S) is soft Np-open set in $(D, \tilde{\sigma}, S)$.

Proof:

i. If (G, S) is soft $\alpha-$open in $\tilde{D}$ and (H, S) is soft $Np-$open in $\tilde{D}$, then for each $\tilde{y} \tilde{\in} (G, S)\tilde{\cap}(H, S)$ there exists a soft p-open set (W, S) in $\tilde{D}$ containing $\tilde{y}$ such that $(W, S) - (H, S)$ is a finite soft set. By Lemma (2.16), $(G, S)\tilde{\cap}(W, S)$ is soft $p-$open. Thus $\forall\ \tilde{y} \tilde{\in} (G, S)\tilde{\cap}(H, S)$, $\exists$ a soft $p-$open subset $(G, S)\tilde{\cap}(W, S)$ of $\tilde{D}$ containing $\tilde{y}$ such that

$$\begin{aligned}&((G, S)\tilde{\cap}(W, S)) - ((G, S)\tilde{\cap}(H, S)) \\ &= ((G, S)\tilde{\cap}(W, S))\tilde{\cap}((G, S)\tilde{\cap}(H, S))^c \\ &= ((G, S)\tilde{\cap}(W, S))\tilde{\cap}((G, S)^c\tilde{\cup}(H, S)^c) \\ &= [((G, S)\tilde{\cap}(W, S))\tilde{\cap}(G, S)^c]\tilde{\cup}[((G, S)\tilde{\cap}(W, S))\tilde{\cap}(H, S)^c] \\ &= [((G, S)\tilde{\cap}(W, S))\tilde{\cap}(H, S)^c] \\ &= ((G, S)\tilde{\cap}(W, S)) - (H, S)\ \tilde{\subseteq}\ (W, S) - (H, S)\end{aligned}$$

But $(W, S)) - (H, S)$ is finite, Thus $((G, S)\tilde{\cap}(W, S)) - ((G, S)\tilde{\cap}(H, S))$ is finite. Hence $(G, S)\tilde{\cap}(H, S)$ is soft $Np-$open.

ii. Let $\tilde{a} \tilde{\in} (P, S)\tilde{\cap}(T, S)$, since (P, S) is soft Np-open in $\tilde{D}$, then $\exists$ a soft $p-$open set (V, S) in $\tilde{D}$ containing $\tilde{a}$ such that $(V, S) - (P, S)$ is a finite soft set. By Proposition (1.13), (ii) we have $(V, S)\tilde{\cap}(T, S)$ is soft $p-$open set in $((T, S), \tilde{\sigma}_{(T,S)}, S)$ such that $\tilde{a} \tilde{\in} (V, S)\tilde{\cap}(T, S)$. Now,

$$\begin{aligned}&((V, S)\tilde{\cap}(T, S)) - ((P, S)\tilde{\cap}(T, S)) \\ &= ((V, S)\tilde{\cap}(T, S))\tilde{\cap}((P, S)\tilde{\cap}(T, S))^c \\ &= ((V, S)\tilde{\cap}(T, S))\tilde{\cap}((P, S)^c\tilde{\cup}(T, S)^c)\end{aligned}$$

$$= [((V,S)\widetilde{\cap}(T,S))\widetilde{\cap}(P,S)^c]\widetilde{\cup}[((V,S)\widetilde{\cap}(T,S))\widetilde{\cap}(T,S)^c)]$$
$$= [((V,S)\widetilde{\cap}(T,S))\widetilde{\cap}(P,S)^c]$$
$$= ((V,S)\widetilde{\cap}(T,S)) - (P,S) \,\widetilde{\subseteq}\, (V,S) - (P,S)$$

But $(V,S) - (P,S)$ is finite, then so is $((V,S)\widetilde{\cap}(T,S)) - ((P,S)\widetilde{\cap}(T,S))$. This shows $(P,S)\widetilde{\cap}(T,S)$ is soft $Np-$ open in $((T,S),\tilde{\sigma}_{(T,S)},S)$.

iii. If (P,S) is a soft Np-open set in $((T,S),\tilde{\sigma}_{(T,S)},S)$, then for each $\tilde{a} \,\widetilde{\in}\, (P,S)$, $\exists$ a soft $p-$ open set (U,S) in $((T,S),\tilde{\sigma}_{(T,S)},S)$ containing $\tilde{a}$ such that $(U,S) - (P,S)$ is a finite soft set. Since (T,S) is soft $p-$ open in $(D,\tilde{\sigma},S)$, then by Proposition (1.13),(iii), (U,S) is soft $p-$ open in $\widetilde{D}$ such that $(U,S) - (P,S)$ is a finite soft set. Hence, (P,S) is soft $Np-$ open in $(D,\tilde{\sigma},S)$.

Corollary 3.18: Let $(D,\tilde{\sigma},S)$ be a S. T. S. Then the soft union of a soft closed (resp. soft $\alpha-$ closed, soft $N-$ closed) set and a soft $Np-$ closed set is soft Np-closed.

Proof: It is obvious.

Corollary 3.19: If $(B,\tilde{\sigma}_B,S)$ is a soft open subspace of $(D,\tilde{\sigma},S)$ and $(E,S) \,\widetilde{\subseteq}\, \widetilde{B} \,\widetilde{\subseteq}\, \widetilde{D}$, then (E,S) is soft Np-open in $\widetilde{D}$ if and only if it is soft Np-open in $\widetilde{B}$.

Proof: It is obvious.

Proposition 3.20: Let $(B,\tilde{\sigma}_B,S)$ be a soft open subspace of $(D,\tilde{\sigma},S)$. If (L,S) is soft Np-open (resp. soft Np-closed) in $\widetilde{D}$, then $(L,S)\widetilde{\cap}\widetilde{B}$ is soft $Np-$ open (soft $Np-$ closed) in $\widetilde{B}$.

Proposition 3.21: If $(D,\tilde{\sigma},S)$ is a soft $\tilde{T}_1$-space with a finite set of parameters, then every non-null soft Np-open set contains a non-null soft p-open set.

Proof: Let (P,S) be a non-null soft Np-open set in $\widetilde{D}$. Since $(P,S) \neq \widetilde{\emptyset}$, let $\tilde{x} \,\widetilde{\in}\, (P,S)$, then there exists a soft p-open set (U,S) in $\widetilde{D}$ containing $\tilde{x}$ such that $(U,S) - (P,S)$ is a finite set. Since $(D,\tilde{\sigma},S)$ is soft $\tilde{T}_1$-space, thus $(M,S) = (U,S) - (P,S) = (U,S)\widetilde{\cap}(P,S)^c$ is a soft closed set.
Hence $\tilde{x} \,\widetilde{\in}\, (U,S) - (M,S) \,\widetilde{\subseteq}\, (P,S)$ and by Proposition (1.7),(i),$(U,S) - (M,S) = (U,S)\widetilde{\cap}(M,S)^c$ is soft p-open.

Remark 3.22: If $(D,\tilde{\sigma},S)$ is not a soft $\tilde{T}_1$-space, then there exists a non-null soft Np-open set which does not contain a non-null soft p-open set.

Example 2.23: Let $D = \{u,v,w\}$, $S = \{s_1,s_2\}$, and let $\tilde{\sigma} = \{\widetilde{D},\widetilde{\emptyset},(P_1,S),(P_2,S),(P_3,S)\}$ be a soft topology over D, where

$$(P_1,S) = \{(s_1,\{u\}),(s_2,\{v\})\}$$
$$(P_2,S) = \{(s_1,\{v\}),(s_2,\{u\})\}$$
$$(P_3,S) = \{(s_1,\{u,v\}),(s_2,\{v,u\})\}$$

Then $(K,S) = \{(s_1,\{w\}),(s_2,\{w\})\}$ is soft $Np-$ open not contains any non-null soft $p-$ open set.

Proposition 3.24: A soft subset (P,S) of $(D,\tilde{\sigma},S)$ is soft Np-open if and only if for each $\tilde{p} \,\widetilde{\in}\, (P,S)$ there exists a soft p-open set (V,S) in $\widetilde{D}$ containing $\tilde{p}$ and a finite soft set (M,S) such that $(V,S) - (M,S) \,\widetilde{\subseteq}\, (P,S)$.

Proof: Let (P,S) be a soft Np-open set in $\widetilde{D}$ and $\tilde{p} \,\widetilde{\in}\, (P,S)$, then there is a soft p-open subset (V,S) of $\widetilde{D}$ containing $\tilde{p}$ such that $(V,S) - (P,S)$ is a finite soft set. Let $(M,S) = (V,S) - (P,S)$

$= (V,S)\widetilde{\cap}(P,S)^c$. Then $(V,S) - (M,S) \cong (P,S)$. Conversely, let $\tilde{p} \cong (P,S)$, then there is a soft p-open subset (V,S) of $\widetilde{D}$ containing $\tilde{p}$ and a finite soft set (M,S) such that $(V,S) - (M,S) \cong (P,S)$. Thus $(V,S) - (P,S) \cong (M,S)$ and $(V,S) - (P,S)$ is a finite soft set.

Proposition 3.25: Let (P,S) be a soft Np-closed subset of $(D,\tilde{\sigma},S)$. Then $(P,S) \cong (G,S)\widetilde{\cup}(F,S)$ for some soft p-closed set (G,S) and a finite soft set (F,S).

Proof: It is obvious.

Proposition 3.26: Let $(B,\tilde{\sigma}_B,S)$ be a soft $p-$clopen subspace of $(D,\tilde{\sigma},S)$. If (K,S) is soft $Np-$closed in $\widetilde{B}$, then (K,S) is soft $Np-$closed in $\widetilde{D}$.

Proof: To show that $\widetilde{D} - (K,S)$ is a soft Np-open set in $\widetilde{D}$. Let $\tilde{x} \cong \widetilde{D} - (K,S)$, then either $\tilde{a} \cong \widetilde{D} - \widetilde{B}$ or $\tilde{a} \cong \widetilde{B} - (K,S)$. If $\tilde{a} \cong \widetilde{D} - \widetilde{B}$, since $\widetilde{B}$ is soft $p-$closed in $\widetilde{D}$, then $\widetilde{D} - \widetilde{B}$ is a soft $p-$open in $\widetilde{D}$, and so it is soft $Np-$open, hence there exist a soft p-open set (W,S) in $\widetilde{D}$ contains $\tilde{a}$ such that $(W,S) - (\widetilde{D} - \widetilde{B})$ is soft finite. Since $(K,S) \cong \widetilde{B}$, then $\widetilde{D} - \widetilde{B} \cong \widetilde{D} - (K,S)$, hence $(W,S) - (\widetilde{D} - (K,S)) \cong (W,S) - (\widetilde{D} - \widetilde{B})$ and $(W,S) - (\widetilde{D} - (K,S))$ is a finite soft set. Thus $\widetilde{D} - (K,S)$ is soft $Np-$open in $\widetilde{D}$. Now, if $\tilde{a} \cong \widetilde{B} - (K,S)$, since $\widetilde{B} - (K,S)$ is a soft $Np-$open in $\widetilde{B}$, then there is a soft $p-$open set (T,S) in $\widetilde{B}$ containing $\tilde{a}$ such that $(T,S) - (\widetilde{B} - (K,S))$ is a finite soft set. Since $\widetilde{B}$ is soft p-open in $\widetilde{D}$, then by Proposition (1.13),(iii), (T,S) is soft p-open in $\widetilde{D}$ such that $(T,S) - (\widetilde{B} - (K,S))$ is a finite soft set. Since $\widetilde{B} \cong \widetilde{D}$, then $\widetilde{B} - (K,S) \cong \widetilde{D} - (K,S)$, hence $(T,S) - (\widetilde{D} - (K,S)) \cong (T,S) - (\widetilde{B} - (K,S))$. Therefore $(T,S) - (\widetilde{D} - (K,S))$ is finite. Thus $\widetilde{D} - (K,S)$ is soft $Np-$open $\widetilde{D}$.
Corollary 3.27: Let $(B,\tilde{\sigma}_B,S)$ be a soft clopen subspace of $(D,\tilde{\sigma},S)$ and $(A,S) \cong \widetilde{B} \cong \widetilde{D}$. Then (A,S) is soft Np-closed in $\widetilde{D}$ if and only if it is soft Np-closed in $\widetilde{B}$.

4. Soft Np-Compact Spaces and Soft Np-Lindelöf Spaces

Definition 4.1: A soft subset (G,S) of $(D,\tilde{\sigma},S)$ is called soft $Np-$compact (resp. soft $Np-$Lindelöf) if each softcover of (G,S) by soft Np-open subsets of $\widetilde{D}$ has a finite (resp. countable) subcover.

Definition 4.2: A S. T. S. $(D,\tilde{\sigma},S)$ is said to be soft $Np-$compact (resp. soft $Np-$Lindelöf) if each soft $Np-$open cover of $\widetilde{D}$ has a finite (resp. countable) subcover.

Proposition 4.3: Each soft $Np-$compact (resp. soft $Np-$Lindelöf) space is soft compact (resp. soft Lindelöf).

Proof: It is obvious.

Proposition 4.4: Each soft $Np-$compact space is soft $Np-$Lindelöf.

Remark 4.5: The converse of Propositions (3.3) and (3.4) are not true in general. We see that by the following examples:

Example 4.6: Let $D = \Re$, S be any set of parameters, and $\tilde{\sigma} = \{\widetilde{\Re}, \widetilde{\emptyset}, (P,S)\}$ be a soft topology over $\Re$, where $P(s) = \{3\}$, for each $s \in S$. Then $(\Re,\tilde{\sigma},S)$ is a soft compact space, but is not soft Np-Lindelöf, since $\{(U,S): U(s) = \{3,a\}, \forall\, s \in S, a \in D\}$ is soft $Np-$open cover of $\widetilde{D}$, which has no countable subcover.

Example 4.7: Let $D = N$, $S = \{s_1, s_2, s_3, \ldots, s_n\}$ be a set of parameters, and $\tilde{\sigma} = \{\tilde{N}, \tilde{\emptyset}, (J, S)\}$ be soft topology over N, where $J(s) = \{4\}$, for each $s \in S$. Since N and S are countable sets, then $(N, \tilde{\sigma}, S)$ is a soft Np-Lindelöf space, but is not soft Np-compact, since $\{(V, S): V(s) = \{4, a\}, \forall\, s \in S, a \in \Re\}$ is soft $Np-$ open cover of $\tilde{N}$ has no finite subcover.

Theorem 4.8: If $(D, \tilde{\sigma}, S)$ is a S. T. S. Then each soft set in $\tilde{D}$ is soft $Np-$compact (resp. soft Np-Lindelöf) if and only if each soft Np-open set in $\tilde{D}$ is soft $Np-$compact (resp. soft $Np-$Lindelöf).

Proof: The necessity is obvious. Conversely, if (G, S) is any soft set in $\tilde{D}$ and $\{(W_\alpha, S): \alpha \in \Omega\}$ is soft cover of (G, S) by soft $Np-$open subsets of $\tilde{D}$. Hence the family $\{(W_\alpha, S): \alpha \in \Omega\}$ is a soft Np-open cover of the soft Np-open set $\tilde{U}\{(W_\alpha,S):\alpha \in \Omega\}$. Then by assumption, there is a finite subfamily $\{(W_{\alpha_i}, S): i = 1, \ldots, n\}$ which covers $\tilde{U}\{(W_\alpha,S):\alpha \in \Omega\}$. This subfamily is also a soft subcover of (G, S). Thus (G, S) is soft Np-compact.

Theorem 4.9: Let $(D, \tilde{\sigma}, S)$ be a S. T. S. with a finite (resp. countable) set of parameters. Then a soft subset (A, S) of $(D, \tilde{\sigma}, S)$ is soft $Np-$compact (resp. soft $Np-$Lindelöf) iff it is soft $p-$compact (resp. soft $p-$Lindelöf).

Proof: Necessity. It follows from the fact every soft p-open set is soft Np-open.
Sufficiency. Suppose that (A, S) is a soft p-compact set and $\{(U_\alpha, S): \alpha \in \Omega\}$ is a soft cover of (A, S) by soft Np-open subsets of $\tilde{D}$. For each $\tilde{a} \,\tilde{\in}\, (A, S)$, there exists $\alpha(\tilde{a}) \in \Omega$ such that $\tilde{a} \,\tilde{\in}\, (U_{\alpha(\tilde{a})}, S)$. Since $(U_{\alpha(\tilde{a})}, S)$ is soft Np-open, then there exists a soft p-open set $(N_{\alpha(\tilde{a})}, S)$ in $\tilde{D}$ such that $\tilde{a} \,\tilde{\in}\, (N_{\alpha(\tilde{a})}, S)$ and $(N_{\alpha(\tilde{a})}, S) - (U_{\alpha(\tilde{a})}, S)$ is a soft finite set. The family $\{(N_{\alpha(\tilde{a})}, S): \tilde{a} \,\tilde{\in}\, (A, S)\}$ is a soft $p-$open cover of (A, S). But (A, S) is soft $p-$compact, hence $\exists\ \tilde{a}_1, \tilde{a}_2, \ldots, \tilde{a}_n$ such that $(A, S) \,\tilde{\subseteq}\, \tilde{U}\{(N_{\alpha(\tilde{a}_i)}, S): i \in I\}$, where $I = \{1,2, \ldots, n\}$. Now, we obtain

$$(A, S) \,\tilde{\subseteq}\, \tilde{U}\{[((N_{\alpha(\tilde{a}_i)}, S) - (U_{\alpha(\tilde{a}_i)}, S))\tilde{U}(U_{\alpha(\tilde{a}_i)}, S)]: i \in I\} = \tilde{U}\{((N_{\alpha(\tilde{a}_i)}, S) - (U_{\alpha(\tilde{a}_i)}, S)): i \in I\}\ \tilde{U}\ (\tilde{U}\{(U_{\alpha(\tilde{a}_i)}, S): i \in I\})$$

For each $\tilde{a}_i$, $(N_{\alpha(\tilde{a}_i)}, S) - (U_{\alpha(\tilde{a}_i)}, S)$ is a soft finite set and there is a finite subset $\Omega(\tilde{a}_i)$ of Ω such that $((N_{\alpha(\tilde{a}_i)}, S) - (U_{\alpha(\tilde{a}_i)}, S))\tilde{\cap}(A, S) \,\tilde{\subseteq}\, \tilde{U}\{(U_\alpha, S): \alpha \in \Omega(\tilde{a}_i)\}$. Therefore, we have
$(A, S) \,\tilde{\subseteq}\, \tilde{U}\{\tilde{U}\{(U_\alpha, S): \alpha \in \Omega(\tilde{a}_i)\}: i \in I\}\ \tilde{U}\ (\tilde{U}\{(U_{\alpha(\tilde{a}_i)}, S): i \in I\})$.
Hence (A, S) is soft Np-compact in $\tilde{D}$.

Corollary 4.10: A S. T. S. $(D, \tilde{\sigma}, S)$ with a finite (resp. countable) set of parameters is soft $Np-$compact (resp. soft $Np-$Lindelöf) iff it is soft $p-$compact (resp. soft $p-$Lindelöf).

Remark 4.11: From Theorem (3.9), if the set of parameters S is not finite (resp. not countable), then each soft $Np-$compact (resp. soft $Np-$Lindelöf) is soft $p-$compact (resp. soft $p-$Lindelöf), but it converse may not be true as shown in the following example:

Example 4.12: Let $D = \Re = S$, $(1, \{1\}) = \tilde{a} \,\tilde{\in}\, \tilde{R}$ and let $\tilde{\sigma} = \{(W, S) \,\tilde{\subseteq}\, \tilde{\Re}: \tilde{a} \,\tilde{\notin}\, (W, S)\}\ \tilde{U}\ \{\tilde{\Re}\}$ be the excluded soft point soft topology over $\Re$. Then $(\Re, \tilde{\sigma}, \Re)$ is a soft p-compact space, but is not soft Np-Lindelöf, since $\{\{\tilde{x}\}\tilde{U}(M, S)^c: \tilde{x} \,\tilde{\in}\, (M, S)\ \&\ M(s) = \{2,3,4,5,6,7,8,9,10\}, \forall\, s \in D\}$ is a soft $Np-$ open cover of $\tilde{D}$ has no countable subcover.

Remark 4.13: Diagram (2) shows the relation among soft Np-compact spaces, soft Np-Lindelöf spaces, and other kinds of soft spaces.

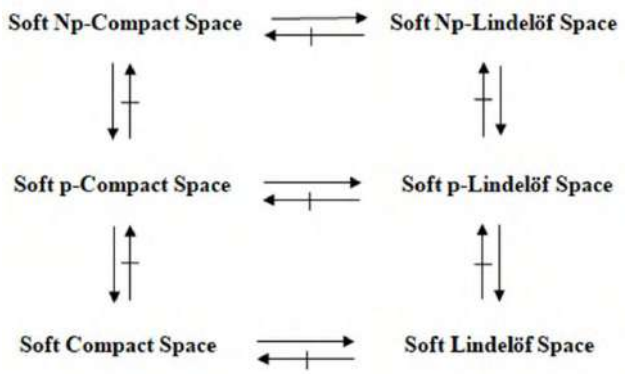

Diagram (2)

Proposition 4.14: Each soft $\mathrm{Np}-$ closed set in a soft $\mathrm{Np}-$ compact (resp. soft $\mathrm{Np}-$Lindelöf) space is soft $\mathrm{Np}-$ compact (resp. soft $\mathrm{Np}-$Lindelöf).

Proof: Assume that (E,S) is soft $\mathrm{Np}-$ closed in a soft $\mathrm{Np}-$ compact space $(D,\tilde{\sigma},S)$, and $\{(V_\alpha,S):\alpha\in\Psi\}$ is a soft cover of (E,S) by soft $\mathrm{Np}-$ open sets in $\tilde{D}$. Since $(E,S)^c$ is soft Np-open, then $\{(V_\alpha,S):\alpha\in\Psi\}\tilde{\cup}(E,S)^c$ is soft $\mathrm{Np}-$ open cover of $\tilde{D}$ which is soft $\mathrm{Np}-$ compact, hence $\exists\ \{(V_{\alpha_i},S)\}_{i=1}^{n}\tilde{\cup}(E,S)^c$ is a finite soft subcover. So $\tilde{D}\cong(\tilde{\cup}\{(V_{\propto_i},S):i=1,\dots n\})\tilde{\cup}\ (E,S)^c$. Thus $(E,S)\cong\tilde{\cup}\{(V_{\propto_i},S):i=1,\dots n\}$. Therefore, (E,S) is soft Np-compact. In the same way, we prove the other case.

Proposition 4.15: Let $(D,\tilde{\sigma},S)$ be a S. T. S. If (E,S) is soft $\mathrm{Np}-$closed and (P,S) is soft $\mathrm{Np}-$ compact (resp. soft $\mathrm{Np}-$Lindelöf) in $\tilde{D}$. Then $(E,S)\tilde{\cap}(P,S)$ is soft $\mathrm{Np}-$ compact (resp. soft $\mathrm{Np}-$Lindelöf) in $\tilde{D}$.

Proof: Let $\{(U_\alpha,S):\alpha\in\Psi\}$ be a soft cover of $(E,S)\tilde{\cap}(P,S)$ by soft Np-open subsets of $\tilde{D}$. Hence $(P,S)\cong\tilde{\cup}\{(U_\alpha,S):\alpha\in\Psi\}\tilde{\cup}(E,S)^c$. Since (P,S) is soft Np-compact, then $\exists\ \{(U_{\alpha_i},S)\}_{i=1}^{n}\tilde{\cup}(E,S)^c$ is a finite soft subcover for (P,S). Thus $(E,S)\tilde{\cap}(P,S)\cong\tilde{\cup}\{(U_{\propto_i},S):i=1,\dots,n\}$. Therefore $(E,S)\tilde{\cap}(P,S)$ is soft Np-compact. In the same way, we can prove the other case.

Proposition 4.16: Let $(B,\tilde{\sigma}_B,S)$ be a soft open subspace of $(D,\tilde{\sigma},S)$. Then $(E,S)\cong\tilde{B}$ is soft Np $-$compact (resp. soft Np-Lindelöf) in $\tilde{B}$ if and only if it is soft $\mathrm{Np}-$ compact (resp. soft $\mathrm{Np}-$Lindelöf) in $\tilde{D}$.

Proof: It follows from Corollary (2.19) and Proposition (2.20).

Definition 4.17: A soft function $h:(D,\tilde{\sigma},S)\to(C,\tilde{\rho},S)$ is called:

i. (Soft Np-continuous if $h^{-1}((E,S))$ is soft $\mathrm{Np}-$ open in $\tilde{D}$ for all soft open set (E,S) in $\tilde{C}$.
ii. Soft Np-irresolute if $h^{-1}((E,S))$ is soft $\mathrm{Np}-$ open in $\tilde{D}$ for all soft $\mathrm{Np}-$ open set (E,S) in $\tilde{C}$.

Proposition 4.18:

i. If $h:(D,\tilde{\sigma},S)\to(C,\tilde{\rho},S)$ is soft Np-irresolute and (E,S) is soft Np-compact (resp. soft Np-Lindelöf) in $\tilde{D}$. Then $h((E,S))$ is soft Np-compact (resp. soft Np-Lindelöf) in $\tilde{C}$.
ii. If $h:(D,\tilde{\sigma},S)\to(C,\tilde{\rho},S)$ is soft Np-continuous and (E,S) is soft Np-compact (resp. soft Np-Lindelöf) in $\tilde{D}$. Then $h((E,S))$ is soft compact (resp. soft Lindelöf) in $\tilde{C}$.

Proof:

i. To show that $h((E,S))$ is a soft Np-compact subset of $\tilde{C}$. Let $\{(V_\alpha,S):\alpha\in\Psi\}$ be a soft cover of $h((E,S))$ by soft Np-open subsets of $\tilde{C}$ that is $h((E,S))\cong\tilde{U}\{(V_\alpha,S):\alpha\in\Psi\}$, so $(E,S)\cong\tilde{U}\{h^{-1}((V_\alpha,S)):\alpha\in\Psi\}$. Since h is soft Np-irresolute, then $\{h^{-1}((V_\alpha,S)):\alpha\in\Psi\}$ is soft $Np-$ open cover of (E,S) which is soft $Np-$ compact, hence $\exists\ \{h^{-1}((V_{\alpha_i},S))\}_{i=1}^{n}$ is a finite soft subcover. Thus $(E,S)\cong\tilde{U}\{h^{-1}((V_{\alpha_i},S)):i=1,\dots n\}$, that is $h((E,S))\cong\tilde{U}\{(V_{\alpha_i},S):i=1,\dots n\}$. Therefore $h((E,S))$ is soft Np-compact.

ii. Similar to (i).

Random Fixed Point on Ishikawa Random Iteration Under Fibonacci Sequence

Random Fixed Point on Ishikawa Random Iteration Under Fibonacci Sequence

Abstract. In this paper, we introduce a new iterations scheme under Fibonacci sequence for Ishikawa random Iteration of the asymptotically random operator and we have some results convergence to a fixed point.

1. Introduction and preliminaries

The development of the theory of random factors is important as a potential generalization of the determinist operator theory and since the operator theory has important roles in the study of operators'. Spacek [1] and Hans [2] established a stochastic analog of the Banach fixed point theorem in a separable complete metric space. Now this area has become a full-fledged research area (see [3],[4],[5],[6], and [7]).

We supposed that B is a uniformly convex, separable Banach space and F is a nonempty closed convex subset of B.

Definition (1.1) [8]: A measurable mapping $\alpha(\upsilon) : \theta \to B$ is a random fixed point of a random operator $P: \theta \times F \to F$ if $P(\upsilon, \alpha(\upsilon)) = \alpha(\upsilon)$, $\upsilon \in \theta$.

Definition (1.2) [9]: Let a random operator $P: \theta \times F \to F$ be an asymptotically nonresponsive random operator if for every $a, b \in F, \Omega(r) \geq 1$, there exist $\{\Omega(r)\}$ a sequence of positive numbers and $\lim_{r\to\infty} \Omega(r) = 1$, such that
$\|P^r(\upsilon, a(\upsilon)) - P^r(\upsilon, b(\upsilon))\| \leq \beta_r \|a(\upsilon) - b(\upsilon)\|$, for each $\upsilon \in \theta$.

Lemma (1.3) [10]: Let $\{g_r\}$, $\{h_r\}$ be two sequences of nonnegative numbers such that
$g_{r+1} \leq (1 + h_r)\, g_r \quad \forall r \in N$.
If $\sum_{r=1}^{\infty} h_r < \infty$, then $\lim_{r\to\infty} g_r$ exists.

Lemma (1.4) [11]: Let B be a space , $0 < p \leq \lambda_r \leq q < 1$. For all $r \in N$ suppose that $\{c_r\}$ and $\{d_r\}$ are two sequences of B such that $\limsup_{r\to\infty} \|c_r\| \leq t$, $\limsup_{r\to\infty} \|d_r\| \leq t$ *and*
$\lim_{r\to\infty} \|\lambda_r c_r + (1 - \lambda_r) d_r\| = t$. Then $\lim_{r\to\infty} \|c_r - d_r\| = 0$.

Definition (1.5) [12]: A space B is said to satisfy the Opial's condition if for any sequence $\{c_r\}$ in B, $c_r \rightharpoonup c$ (weakly) as $r \to \infty$ and $c \neq d$ implying that $\lim_{r\to\infty} \sup\|c_r - c\| < \lim_{r\to\infty} \sup\|c_r - d\|$

Theorem (1.6) : Let F be a subset of space B which satisfies Opial's condition and let $P: \theta \times F \to F$ be an asymptotically nonexpansive random operator. Then $(I - P)$ is demiclosed at zero, if $\alpha_r(\upsilon): \theta \to$such that $\alpha_r(\upsilon) \rightharpoonup \zeta(\upsilon)$ and $\lim_{r\to\infty} \sup\left\|P\big((\upsilon), \alpha_r(\upsilon)\big) - \alpha_r(\upsilon)\right\| = 0$, then
$(I - P)\big(\upsilon, \omega(\upsilon)\big) = 0$ Which means led to $P\big(\upsilon, \omega(\upsilon)\big) = \omega(\upsilon)$.

Definition (1.6): [13] (Fibonacci sequence): Let $\{\Omega(r)\}$ be a Fibonacci sequence if $\Omega(r+1) = \Omega(r) + \Omega(r-1)$, where $\Omega(0) = \Omega(1) = 1, \forall\, r \geq 1$.

2. Main results

Through this work, we obtain theorems in the stochastic fixed point with the effect of the Fibonacci sequence.

Definition (2.1): Let F be a subset of space $(B, \|\,.\,\|)$, and let $P: \theta \times F \to F$ be a random operator. Fix $\alpha_0(\upsilon) \in F$ and $\{\lambda_r\}, \{\aleph_r\} \subset [0,1]$. The random Fibonacci- Ishikawa iteration is defined by
$\alpha_{r+1}(\upsilon) = \lambda_r P^{\Omega(r)}\big((\upsilon), \beta_r(\upsilon)\big) + (1 - \lambda_r)\alpha_r(\upsilon)$
$\beta_r(\upsilon) = (\,(1 - \aleph_r)\alpha_r(\upsilon) + \aleph_r P^{\Omega(r)}\big((\upsilon), \alpha_r(\upsilon)\big)$
For each $\in N$, where $\{\Omega(r)\}$ is the Fibonacci sequence.
Where $\{\lambda_r\} \subset [0,1]$ if $0 < a \leq \lambda_r, \aleph_r \leq b < 1$.

Proposition (2.2) Let F be a subset of B. Let $P: \theta \times F \to F$ satisfies Definition (1.2) and $\{\alpha_r(\upsilon)\}$ the sequence satisfies Definition (2.1) which is bounded. If $\sum\big(\delta_{\Omega(r)} - 1\big) < \infty$, RP is nonempty set of a fixed point on P, then $\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\|$exists, $\forall \omega(\upsilon) \in RP$.

Proof: Let $\omega(\upsilon) \in RP$, then

$$\begin{aligned}
\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\| &= \left\|\lambda_r P^{\Omega(r)}\big((\upsilon), \beta_r(\upsilon)\big) + (1 - \lambda_r)\alpha_r(\upsilon) - \omega(\upsilon)\right\| \\
&= \left\|(1 - \lambda_r)\big(\alpha_r(\upsilon) - \omega(\upsilon)\big) + \lambda_r\left(P^{\Omega(r)}\left((\upsilon), \beta_r(\upsilon)\right) - \omega(\upsilon)\right)\right\| \\
&\leq (1 - \lambda_r)\|\alpha_r(\upsilon) - \omega(\upsilon)\| + \lambda_r\left\|P^{\Omega(r)}\left((\upsilon), \beta_r(\upsilon)\right) - \omega(\upsilon)\right\| \\
&\leq \delta_{\Omega(r)}\left\|\beta_r(\upsilon) - \omega(\upsilon)\right\| \\
\left\|\beta_r(\upsilon) - \omega(\upsilon)\right\| &= \left\|(1 - \aleph_r)\alpha_r(\upsilon) + \aleph_r P^{\Omega(r)}\big((\upsilon), \alpha_r(\upsilon)\big) - \omega(\upsilon)\right\| \\
&= \left\|(1 - \aleph_r)\big(\alpha_r(\upsilon) - \omega(\upsilon)\big) + \aleph_r\left(P^{\Omega(r)}\big((\upsilon), \alpha_r(\upsilon)\big) - \omega(\upsilon)\right)\right\| \\
&\leq (1 - \aleph_r)\|\alpha_r(\upsilon) - \omega(\upsilon)\| + \aleph_r\left\|P^{\Omega(r)}\big((\upsilon), \alpha_r(\upsilon)\big) - \omega(\upsilon)\right\| \\
&\leq \delta_{\Omega(r)}\|\alpha_r(\upsilon) - \omega(\upsilon)\|.
\end{aligned}$$

Therefore, $\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\| \leq {\delta_{\Omega(r)}}^2\|\alpha_r(\upsilon) - \omega(\upsilon)\| = \left(1 + \left({\delta_{\Omega(r)}}^2 - 1\right)\right)\|\alpha_r(\upsilon) - \omega(\upsilon)\|$
By Lemma (1.3), we have $\lim_{\upsilon\to\infty}\|\alpha_r(\upsilon) - \omega(\upsilon)\| = t$, exists, $\forall\, t \geq 0$.

Theorem (2.3): Let $B, F, P, RP, \{\alpha_r(\upsilon)\}$ satisfies in Proposition 2.2, B is Opial's condition.
If $\sum\big({\delta_{\Omega(r)}}^2 - 1\big) < \infty$ then $\{\alpha_r(\upsilon)\}$ converges weakly to a fixed point.

Proof*:* By Proposition 2.2, $\lim_{r\to\infty}\|\alpha_r(\upsilon) - \omega(\upsilon)\|$ exists. This implies that $\{\alpha_r(\upsilon)\}$ is bounded**,** to prove that

$\lim_{r\to\infty}\|\alpha_r(\upsilon) - P((\upsilon),\alpha_r(\upsilon))\| = 0$, and

$\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\| = \left\|(1-\lambda_r)(\alpha_r(\upsilon)-\omega(\upsilon)) + \lambda_r\left(P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \omega(\upsilon)\right)\right\|$

$\lim_{r\to\infty}\sup\left\|P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \omega(\upsilon)\right\| \le t$

$\lim_{r\to\infty}\sup\|P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon)) - \omega(\upsilon)\| \le t$

Also $t = \lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\|$, then $t \le \lim_{r\to\infty}\inf\|\beta_r(\upsilon) - \omega(\upsilon)\|$

Since $\|\alpha_r(\upsilon) - \omega(\upsilon)\| = t$ and $\|\beta_r(\upsilon) - \omega(\upsilon)\| \le \|P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon)) - \omega(\upsilon)\|$

Thus $\sup\|\beta_r(\upsilon) - \omega(\upsilon)\| \le t$. Therefore $\lim_{r\to\infty}\|\beta_r(\upsilon) - \omega(\upsilon)\| = t$

$$t = \lim_{r\to\infty}\|\beta_r(\upsilon) - \omega(\upsilon)\| = \lim_{r\to\infty}\|(1-\gimel_r)\alpha_r(\upsilon) + \gimel_r P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon)) - \omega(\upsilon)\|$$
$$= \lim_{r\to\infty}\left\|(1-\gimel_r)(\alpha_r(\upsilon)-\varrho) + \gimel_r\left(P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon)) - \omega(\upsilon)\right)\right\|$$

By Lemma (1.4), we have $\lim_{r\to\infty}\|P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon)) - \alpha_r(\upsilon)\| = 0$, next,

$$t = \lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\| = \lim_{r\to\infty}\left\|(1-\lambda_r)\alpha_r(\upsilon) + \lambda_r P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \omega(\upsilon)\right\|$$
$$= \lim_{r\to\infty}\left\|(1-\lambda_r)(\alpha_r(\upsilon)-\omega(\upsilon)) + \lambda_r\left(P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \omega(\upsilon)\right)\right\|$$

By Lemma (1.4), we have $\lim_{r\to\infty}\left\|P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \omega(\upsilon)\right\| = 0$

$$\|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\|$$
$$\le \|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\beta_r(\upsilon))\| + \|P^{\Omega(r)}((\upsilon),\beta_r(\upsilon)) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\|$$
$$\|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\|$$
$$\le \left\|(1-\lambda_r)\alpha_r(\upsilon) + \lambda_r P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right)\right\|$$
$$+ \left\|P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \alpha_r(\upsilon)\right\| + \|\alpha_r(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\|$$
$$= \left\|(1-\lambda_r)\left(\alpha_r(\upsilon) - P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right)\right)\right\| + \left\|P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \alpha_r(\upsilon)\right\|$$
$$+ \|\alpha_r(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\|$$
$$\le (1-\theta_\upsilon)\left\|\alpha_r(\upsilon) - P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right)\right\| + \left\|P^{\Omega(r)}\left((\upsilon),\beta_r(\upsilon)\right) - \alpha_r(\upsilon)\right\|$$
$$+ \|\alpha_r(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\|$$

By limit of sides as $r \to \infty$ then

$\lim_{r\to 0}\|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\|$.

Thus $\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - \alpha_r(\upsilon)\| = 0$

$$\|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_{r+1}(\upsilon))\|$$
$$\le \|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\| + \|P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon)) - P^{\Omega(r)}((\upsilon),\alpha_{r+1}(\upsilon))\|$$
$$\le \|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_r(\upsilon))\| + \delta_{\Omega(r)}\|\alpha_r(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_{r+1}(\upsilon))\|$$

since, $\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - P^{\Omega(r)}((\upsilon),\alpha_{r+1}(\upsilon))\| = 0$.

Thus $\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - P^{\Omega(r)+1}((\upsilon),\alpha_{r+1}(\upsilon))\| = 0$

We have $\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - P((\upsilon),\alpha_{r+1}(\upsilon))\| = 0$

$$\|\alpha_{r+1}(\upsilon) - P((\upsilon),\alpha_{r+1}(\upsilon))\|$$
$$\le \|\alpha_{r+1}(\upsilon) - P^{\Omega(r)+1}((\upsilon),\alpha_{r+1}(\upsilon))\|$$
$$+ \|P^{\Omega(r)+1}((\upsilon),\alpha_{r+1}(\upsilon)) - P^{\Omega(r)+1}((\upsilon),\alpha_r(\upsilon))\|$$
$$+ \|P^{\Omega(r)+1}((\upsilon),\alpha_r(\upsilon)) - P((\upsilon),\alpha_{r+1}(\upsilon))\|$$

$$\leq \left\|\alpha_{r+1}(\upsilon) - P^{\Omega(r)+1}\left((\upsilon), \alpha_{r+1}(\upsilon)\right)\right\| + \delta_{\Omega(r)}\|\alpha_{r+1}(\upsilon) - \alpha_r(\upsilon)\|$$
$$+ \delta_1\left\|P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - \alpha_{r+1}(\upsilon)\right\|$$
$$\left\|\alpha_r(\upsilon) - P\left((\upsilon), \alpha_r(\upsilon)\right)\right\|$$
$$= \|\alpha_r(\upsilon) - \alpha_{r+1}(\upsilon)\| + \left\|\alpha_{r+1}(\upsilon) - P\left((\upsilon), \alpha_{r+1}(\upsilon)\right)\right\|$$
$$+ \left\|P\left((\upsilon), \alpha_{r+1}(\upsilon)\right) - P\left((\upsilon), \alpha_r(\upsilon)\right)\right\|$$
$$\leq \|\alpha_r(\upsilon) - \alpha_{r+1}(\upsilon)\| + \left\|\alpha_{r+1}(\upsilon) - P\left((\upsilon), \alpha_{r+1}(\upsilon)\right)\right\| + \delta_1\|\alpha_{r+1}(\upsilon) - \alpha_r(\upsilon)\|$$

Thus $\lim_{r\to\infty}\left\|\alpha_r(\upsilon) - P\left((\upsilon), \alpha_r(\upsilon)\right)\right\| = 0$. The sequence $\{\alpha_r(\upsilon)\}$ is bounded, so there exists a subsequence $\{\alpha_{ri}(\upsilon)\}$ of $\{\alpha_r(\upsilon)\}$ such that$\alpha_{ri}(\upsilon) \to \mu(\upsilon)$ by $\left\|\alpha_{ri}(\upsilon) - P\left((\upsilon), \alpha_{ri}(\upsilon)\right)\right\| = 0$ .And by

lemma (1.4) we get $\mu(\upsilon) \in RP$.

We show that $\{\alpha_r(\upsilon)\}$ converges weakly to $\mu(\upsilon)$. Let $\{\alpha_{ri}(\upsilon)\}$ of $\{\alpha_r(\upsilon)\}$ such that$\alpha_{ri}(\upsilon) \rightharpoonup \mathfrak{z}(\upsilon)$ for some $\mathfrak{z}(\upsilon) \in F$ and again above conclude that $\mathfrak{z}(\upsilon) \in RP$, now we show that $\mu(\upsilon) = \mathfrak{z}(\upsilon)$, we assume that $\mu(\upsilon) \neq \mathfrak{z}(\upsilon)$.

Since $\lim_{\upsilon\to\infty}\|\alpha_r(\upsilon) - \varrho\|$ exists for every $\varrho \in D_f$, and since $\mu(\upsilon), \mathfrak{z}(\upsilon) \in RP$, by Opial's condition, we have that

$$\lim_{r\to\infty}\|\alpha_r(\upsilon) - \mu(\upsilon)\| = \lim_{ri\to\infty}\|\alpha_{ri}(\upsilon) - \mu(\upsilon)\| < \lim_{ri\to\infty}\|\alpha_{ri}(\upsilon) - \mathfrak{z}(\upsilon)\| = \lim_{rj\to\infty}\left\|\alpha_{rj}(\upsilon) - \mathfrak{z}(\upsilon)\right\| =$$
$$\lim_{rj\to\infty}\left\|\alpha_{rj}(\upsilon) - \mu(\upsilon)\right\| = \lim_{\upsilon\to\infty}\|\alpha_r(\upsilon) - \mu(\upsilon)\|.$$

This $\lim_{\upsilon\to\infty}\|\alpha_r(\upsilon) - \mu(\upsilon)\| < \lim_{\upsilon\to\infty}\|\alpha_r(\upsilon) - \mu(\upsilon)\|$, which is a contradiction, so we get that $\mu(\upsilon) = \mathfrak{z}(\upsilon)$.

Proposition 2.4 Let B, F, P, RP, satisfies in Proposition 2.2 and$\{\alpha_r(\upsilon)\}$ satisfies Definition (2.1) if $\aleph_r = 0$ which is bounded. If $\sum\left(\delta_{\Omega(r)} - 1\right) < \infty$, then $\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\|$exists, $\forall\omega(\upsilon) \in RP$.

Proof*:* Let $\omega(\upsilon) \in RP$, then

$$\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\| = \left\|\lambda_r P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) + (1-\lambda_r)\alpha_r(\upsilon) - \omega(\upsilon)\right\|$$
$$= \left\|\lambda_r\left(P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - \omega(\upsilon)\right) + (1-\lambda_r)\left(\alpha_r(\upsilon) - \omega(\upsilon)\right)\right\|$$
$$\leq \left\|\lambda_r\left(P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - \omega(\upsilon)\right)\right\| + \left\|(1-\lambda_r)\left(\alpha_r(\upsilon) - \omega(\upsilon)\right)\right\|$$
$$= \lambda_r\left\|P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - \omega(\upsilon)\right\| + (1-\lambda_r)\left\|P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - \omega(\upsilon)\right\|$$
$$\leq \lambda_r\delta_{\Omega(r)}\|\alpha_r(\upsilon) - \omega(\upsilon)\| + (1-\lambda_r)\|\alpha_r(\upsilon) - \omega(\upsilon)\|$$
$$= \delta_{\Omega(r)}\|\alpha_r(\upsilon) - \omega(\upsilon)\| = \left(1 + \left(\delta_{\Omega(r)} - 1\right)\right)\|\alpha_r(\upsilon) - \omega(\upsilon)\|$$

By Lemma (1.3), we get $\lim_{r\to\infty} = t$ exists, $\forall\, t \geq 0$.

Theorem 2.5 Let $B, F, P, RP, \{\alpha_r(\upsilon)\}$ satisfies in Proposition 2.4, B is Opial's condition. If $\sum\left(\delta_{\Omega(r)} - 1\right) < \infty$ then $\{\alpha_r(\upsilon)\}$ converges weakly to a fixed point.

Proof: since proposition (2.4), $\lim_{r\to\infty}\|\alpha_r(\upsilon) - \omega(\upsilon)\|$ exists. This implies that $\{\alpha_r(\upsilon)\}$ is bounded.

We prove that $\lim_{r\to\infty}\left\|P\left((\upsilon), \alpha_r(\upsilon)\right) - \alpha_r(\upsilon)\right\| = 0$.

$$\lim_{r\to\infty}\left\|P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - \omega(\upsilon)\right\|$$
$$= \lim_{r\to\infty}\left\|P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - P^{\Omega(r)}\left((\upsilon), \omega(\upsilon)\right)\right\| \leq \lim_{r\to\infty}\delta_{\Omega(r)}\|\alpha_r(\upsilon) - \omega(\upsilon)\|$$
$$= \lim_{r\to\infty}\left(1 + \left(\delta_{\Omega(r)} - 1\right)\right)\|\alpha_r(\upsilon) - \omega(\upsilon)\| = t$$

And $\lim_{r\to\infty}\|\alpha_{r+1}(\upsilon) - \omega(\upsilon)\| = \left\|\lambda_r\left(P^{\Omega(r)}\left((\upsilon), \alpha_r(\upsilon)\right) - \omega(\upsilon)\right) + (1-\lambda_r)\left(\alpha_r(\upsilon) - \omega(\upsilon)\right)\right\| = t.$

$$\lim_{r\to\infty}\|\alpha_{r+1}(v)-\omega(v)\| = \left\|\lambda_r\left(P^{\Omega(r)}\big((v),\alpha_r(v)\big)-\omega(v)\right)+(1-\lambda_r)\big(\alpha_r(v)-\omega(v)\big)\right\| = t.$$

$$\begin{aligned}\left\|\alpha_{r+1}(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\| &= \left\|\lambda_r P^{\Omega(r)}\big((v),\alpha_r(v)\big)+(1-\lambda_r)\alpha_r(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\|\\ &= \left\|(1-\lambda_r)\alpha_r(v)+(\lambda_r-1)P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\|\\ &= \left\|(1-\lambda_r)\left(\alpha_r(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right)\right\|\\ &= (1-\theta_v)\left\|\alpha_r(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\|\end{aligned}$$

Also $\lim_{r\to\infty}\left\|\alpha_{r+1}(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\| = 0$, and

$$\|\alpha_{r+1}(v)-\alpha_r(v)\| \le \left\|\alpha_{r+1}(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\| + \left\|P^{\Omega(r)}\big((v),\alpha_r(v)\big)-\alpha_r(v)\right\|$$

Then $\lim_{r\to\infty}\|\alpha_{r+1}(v)-\alpha_r(v)\| = 0$. So

$$\begin{aligned}&\left\|\alpha_{r+1}(v)-P^{\Omega(r)}\big((v),\alpha_{r+1}(v)\big)\right\|\\ &\quad\le \left\|\alpha_{r+1}(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\| + \left\|P^{\Omega(r)}\big((v),\alpha_r(v)\big)-P^{\Omega(r)}\big((v),\alpha_{r+1}(v)\big)\right\|\\ &\quad\le \left\|\alpha_{r+1}(v)-P^{\Omega(r)}\big((v),\alpha_r(v)\big)\right\| + \delta_{\Omega(r)}\|\alpha_{r+1}(v)-\alpha_r(v)\|\end{aligned}$$

$\lim_{r\to\infty}\left\|\alpha_{r+1}(v)-P^{\Omega(r)}\big((v),\alpha_{r+1}(v)\big)\right\| = 0$, then $\lim_{r\to\infty}\left\|\alpha_{r+1}(v)-P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)\right\| = 0$

$$\begin{aligned}&\left\|\alpha_{r+1}(v)-P\big((v),\alpha_{r+1}(v)\big)\right\|\\ &\quad\le \left\|\alpha_{r+1}(v)-P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)\right\|\\ &\quad+ \left\|P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)-P^{\Omega(r)+1}\big((v),\alpha_r(v)\big)\right\|\\ &\quad+ \left\|P^{\Omega(r)+1}\big((v),\alpha_r(v)\big)-P\big((v),\alpha_{r+1}(v)\big)\right\|\\ &\quad\le \left\|\alpha_{r+1}(v)-P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)\right\| + \delta_{\Omega(r)+1}\|\alpha_{r+1}(v)-\alpha_r(v)\|\\ &\quad+ \delta_1\left\|P^{\Omega(r)}\big((v),\alpha_r(v)\big)-\alpha_{r+1}(v)\right\|\end{aligned}$$

By taking the limit as $r\to\infty$ then $\lim_{r\to\infty}\left\|\alpha_{r+1}(v)-P\big((v),\alpha_{r+1}(v)\big)\right\| = 0$. Also

$$\begin{aligned}&\left\|\alpha_r(v)-P\big((v),\alpha_r(v)\big)\right\|\\ &\quad\le \left\|\alpha_r(v)-P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)\right\| + \left\|P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)-P\big((v),\alpha_r(v)\big)\right\|\\ &\quad\le \|\alpha_r(v)-\alpha_{r+1}(v)\| + \left\|\alpha_{r+1}(v)-P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)\right\|\\ &\quad+ \left\|P^{\Omega(r)+1}\big((v),\alpha_{r+1}(v)\big)-P\big((v),\alpha_r(v)\big)\right\|\end{aligned}$$

Therefore $\left\|\alpha_r(v)-P\big((v),\alpha_r(v)\big)\right\| = 0$.

Show that , $\mu(v)=\rho(v)$, we assume that $\mu(v)\neq\rho(v)$, since $\lim_{r\to\infty}\|\alpha_r(v)-\omega(v)\|$ exist for every $\omega(v)\in RP$, and since $\mu(v),\rho(v)\in RP$, by Opial's condition, we have that

$$\begin{aligned}\lim_{r\to\infty}\|\alpha_r(v)-\mu(v)\| &= \lim_{ri\to\infty}\|\alpha_{ri}(v)-\mu(v)\| < \lim_{ri\to\infty}\|\alpha_{ri}(v)-\rho(v)\| = \lim_{rj\to\infty}\left\|\alpha_{rj}(v)-\rho(v)\right\|\\ &= \lim_{rj\to\infty}\left\|\alpha_{rj}(v)-\mu(v)\right\| = \lim_{r\to\infty}\|\alpha_r(v)-\mu(v)\|\end{aligned}$$

This $\lim_{r\to\infty}\|\alpha_r(v)-\mu(v)\| < \lim_{r\to\infty}\|\alpha_r(v)-\mu(v)\|$, which is a contradiction, then $\mu(v)=\rho(v)$.

Choosing the best eestimated regression equation for data subject to geometric distribution (Student data as a case study)

Choosing the best eestimated regression equation for data subject to geometric distribution (Student data as a case study)

Osanma Abdulazeez kadhim Al-Quraishi

Ministry of Education, Iraq

E-mail: ousamastat@gmail.com

Abstract. The geometric distribution is one of the discrete statistical distributions that is important, especially in the of population statistics, such as studying population growth and death and birth rates ,The discrepancy in the quality of the estimated regression models and the inability to use some models of them because they do not possess the characteristics of good estimates , lead to a lack of confidence in their predictive or estimated accuracy, which necessitated the study of the geometric distribution to which the data are subject and the estimation of the distribution regression equation using some of the parameter estimation methods (kernel regression method , Liu method) for data represented by preparing secondary students in the holy Karbala governorate with 50 views, and after the comparison between the results of estimating the two methods using the Standards Comparison (AIC, BIC, MSE) and determining the optimal way to estimate the geometric distribution equation The kernel regression is the best because it has the smallest values of the Standards Comparison and was used for the purpose of predicting the preparation of secondary students for the time period (2021-2030).

1. Introduction and research methodology

There are many mathematical models, the most important of which are regression equations, especially the transformed equations from statistical distributions that are used to predict, The study of choosing the appropriate distribution for a phenomenon and methods for estimating the regression models converted by logarithmic transformation began in the last century. In 1986,the two researchers(Cameron & Trived) [7] used the Poisson regression model, estimated its parameters and news of those parameters, and applied it in modeling numerical data that represent the number of medical consultations provided. And in (2005) the researcher (CHANG) [8] in a comparative study between the negative binomial regression method and the artificial neural network method (ANN) applied it to road accident data in the state of New York, USA, for the purpose of analyzing these data and predicting with them. Negative binomial regression in prediction as the relationship between variables does not affect the validity of the model .In (2007) the two researchers (WANG & ETIENNE) [14] used the Poisson regression model and the negative binomial model to predict road accidents. In 2019, the two researchers (Shorouk & Adnan) [4]assessed the parameters of the binomial regression model to study the factors affecting the increase in congenital anomalies in Iraq,Also in the same year, two researchers (Abd al-Hussain and Abd al-Amir) [1] used the Poisson regression model estimated in the manner of the greatest possible way to predict road accidents see. So the researcher decided to use the geometric regression model for

the purpose of predicting the preparation of secondary students in the holy governorate of Karbala after the data are subject to geometric distribution, using non-parametric methods to estimate the regression equation because these methods deal with high flexibility with random error assumptions and this does not affect the efficiency of the capabilities, as they are mainly based On the data, the data type explains the actual shape of the regression curve.

1.1 research problem

The varince in the quality of the estimated regression models and the inability to use some models of them because they do not have the characteristics of good estimates, which leads to lack of confidence in their predictive or estimated accuracy.

1.2 The research objective

The research aims to:

1-Estimation of the geometric distribution slope equation using some non-parameter estimation methods (kernel regression method, leo method).

2-Differentiating between the results of estimating the two methods using the Standards Comparison (AIC, BIC, MSE) and determining the best method for estimating the geometric distribution equation.

3-Predicting Prepare of secondary students in the holy city of Karbala for the period of time (2021-2030).

1-3: Research Limits:

The limits of the research were temporal, the preparation of secondary students for the period of time (1969-2019), spatially the number of secondary students for the holy Karbala Governorate.

1-5 Data sources :The data was taken from the Ministry of Planning / the Central Statistical Organization/the statistical group.

2- Theoretical aspect:

2-1: Geometric Distribution: [3]

This distribution belongs to the family of discrete distributions and distribution is important in statistical applications, especially in the population statistics when studying population growth rates and mortality and birth rates, and the geometric distribution is part of the probability distribution related to Bernoulli experiments, as we can know the probability density function of the geometric distribution is the number of attempts Failed to try until the first success of that experiment. If the variable (Y) indicates the number of times the experiment was repeated, (θ) indicates the probability of success of the experiment, (1- θ) the probability of the experiment failing, then the probabilistic function of this distribution will be:

$$P(Y,\theta) = \theta.(1-\theta)^{y} \quad , 0 < \theta < 1 \, , Y = 0,1,2,\dots \, , \qquad (1)$$

2-2 :Some characteristics of the Geometric distribution:[3]

1- mean of the variable Y is:

$$M(Y) = EY = \frac{\theta}{(1-\theta)} \quad \dots(2)$$

2- mode of the variable Y is: $M_o(Y)=0$ …(3)

3- median of the variable Y is:

$$M_e(Y) = \left[\frac{-1}{\log_2(1-\theta)}\right] - 1 \quad \dots(4)$$

4- variance of the variable Y is:

$$V(Y) = \frac{\theta}{(1-\theta)^2} \qquad \dots(5)$$

5- Skewness of the variable Y is:

$$S_k(Y) = \frac{2-\theta}{\sqrt{1-\theta}} \quad ...(6)$$

6- Kurtosis of the variable Y is :

$$E_x(Y) = 6 + \frac{\theta^2}{1-\theta} \quad ...(7)$$

7- Cumulative function of the variable Y is:

$$F(Y) = 1-\theta^y \quad , Y = 0,1,2,...n \qquad (8)$$

8-Moment generating functions of the variable Y is:

$$M_{Y(t)} = \frac{\theta}{1-\theta e^t} \quad ...(9)$$

2-3 :Regression Analysis: [2]

Regression analysis is one of the methods or statistical tools that are most used in most research in general because it describes the relationship between variables in the form of an equation, and it is defined as a Statistical Tool used to know the relationship between one or more independent variables And dependent Variable.

Regression analysis is important because it is used for several important purposes:

1- Data Descriotion: Find the regression equation that summarizes or describes the data available to the researcher.

2- Estimation of Parameters: Estimation of the regression equation parameters used in the description of data to infer the strength and direction of the relationship between the variables.

3- Prediction: Estimating and predicting the values of the dependent variable in the future to benefit planning and decision making.

4- Contoral: Control of the results of the dependent variable when changing the values of the independent variables. Geometric Regression Mode [13],[2] The geometric regression model is one of the non-linear regression models, and it is converted into one of the Log-Linear Models by taking the natural logarithm of the geometric distribution equation, so it turns into a linear formula. Geometric regression can also be defined as the method by which the dependent variable is modeled when the values of the variable are as Count Data or as Rate Data. The geometric regression equation can be obtained from the geometric distribution as follows:

Let the variable (Y) follow the geometric distribution with the parameter (θ), and that (X) represents the explanatory variable (time) we can write the geometric distribution equation in the following form:

$$Y = \theta(1-\theta)^x \quad ...(10)$$

Taking the logarithm of both sides of the equation, we get a first degree linear equation:

$\ln(Y) = \ln(\theta) + Xln(1-\theta)$

Assuming below, we obtain an equation (13) representing the estimated linear regression model for the geometric distribution as follows:

$$\ln(\theta) = b_0$$
$$\ln(1-\theta) = b_1$$
$$lny = y^*$$
$$y^* = b_0 + b_1 x_i + e_i \quad ...(11)$$

In the case of taking the exponential function of both sides of equation (13), we obtain the non-linear discretionary regression model for the geometric distribution as follows :

$$y = e^{b_0 + b_1 x_i + e_i} \quad ...(12)$$

2-4: Hypothesis of linear regression of random error: [11]

1- Random error (ui) is normal distributed with an average of zero (E(ui) = 0) and constant variance equal($V(u_i) = \sigma^2$), meaning that:

$u_i \sim N(0, \sigma^2)$ ...(13)

2- Successive errors in the simple linear regression model should not be related to each other, meaning that:

Cov (u_i , u_j)=0 …(14)

3-The random variable(ui)and the explanatory variable (xi)are independent of each other. meaning that:

Cov (x_i , u_i)=0 …(15)

Methods for Estimating the Geometric Regression Model:2-7

There are many methods for estimating the geometric regression model. In this paragraph, we will address the non-parametric methods that assume that random error is distributed with an average of (0) and a constant variance of (σ ^ 2), the fact that non-parametric methods deal with high flexibility with random error assumptions and this does not affect the efficiency of the estmates , Since it is mainly based on data and the data type explains the actual shape of the regression curve, and the methods are.

1. Kernel regression method: [9], [10]

The kernel regression method is one of the non-parametric methods that can be used to estimate the regression equation for the geometric distribution, and the kernel regression method was proposed by the scientists Nadaraya and Watson in (1964) by means of the logarithm of the maximum function, it can be rewritten as follows:

LE(Y_i)=$L(\theta_i) = \frac{1}{n}\{e^{\eta(x_i)}\text{-}y_i\ \eta(x_i)\}$ …(16)

As :

Model Parameters Vector$\eta(x_i)$:

$\eta(x_i)$ = ln[$\theta(x_i)$]

The kernel method is summarized in estimate. Using the following linear model:

$\eta(x_i)$ = b_0 +w' ϕ (x_i) … (19)

AS:

$$w'\ \phi\ (x_i) = \mathrm{K}(x_i, x_l)$$

k(x_i, x_l): is one of the kernel functions.

We get the vector of the geometric regression equation parameter by the kernel method η(xi) by minimizing the logarithm of the Penalizied Negative Log-Likelihood.

L(w,b)=$\sum_{i=1}^{n}[e^{b_0 +w'\ \phi\ (x_i)} - \ y_i(b_0 +w'\ \phi\ (x_i))]+\frac{\lambda}{2}+\|w\|^2$ …(17)

AS:

λ: Penalty Parameter and its function is to control the balance between Goodness of Fit based on two main factors: data and smoothness (Smoothness‖w‖^2) for the function η (x i), which The logarithm of the function of the negative penalties is made at the lower end of it, And on it the Vector parameters of the model η (x i) is written according to the following form:

$\eta(x_i)$ = b_0 +$k_i'\alpha$ …(18)

As:

b0: fixed border.

ki: column i in the kernel matrix of degree (n * n) and its elements k(xi,xl) and (i, l) = 1, 2, 3, …… .n

α: smoothing parameters vector with degree (n * 1).

Thus, the formula for the logarithm of the negative penalty maximum function is written as follows:

L(b_0, α)=$\sum_{i=1}^{n}[e^{b_0 +k_i'\alpha} - \ y_i(b_0 +k_i'\alpha)] + \frac{\lambda}{2}\ \alpha^t\ k\alpha$ …(19)

To obtain maximum likelihood estimates of the nonlinear regression equations in which the dependent variable(Y) follows the geometric distribution, estimates can be obtained using numerical estimation methods such as the Newton-Ravson method and the least squares method for multi-stage repetitive weights (Lterative Reweighted Least Squares), The second method (irls) is easier than the first method (Newton - Rafson) in deriving the cross-validation Criterion (cvc), which has a rate of convergence lower than the rate of convergence in the method of Newton - Rafson .

In order to obtain maximum estimates for the unknown parameters (b0, α), we first find the partial derivatives of the logarithm of the Negative penalty maximum function with respect to the parameter α and the parameter(b0), and then equate the derivative to zero Secondly, my agencies:

$$\begin{pmatrix} \frac{\partial l(b_0,\alpha)}{\partial b_0} = 0 \\ \frac{\partial l(b_0,\alpha)}{\partial \alpha} = 0_n \end{pmatrix} \quad \ldots(20)$$

Solve the following formula using the least squares method for the multi-stage repeated weights (i.r.l.s):

$V'WV + U)\ \beta = V'W\ y^*$ …(21)

As:

) value of the dependent variable converted to linear formula Ln (y : y^*

V: matrix with degree ((n + 1) * n) defined as follows:

$V = (1_n , k)$ …(22)

As:

In: the correct one-degree vector (n * 1).

k: The kernel matrix contained in the formula (21)

W: Diagonal matrix with degree (n * n) written as :

W = daig [exp($b_0 + k_1'\alpha$) , ……..,($b_0 + k_n'\alpha$)] … (23)

B: The vector parameters to be Estimated are of the same degree((n+1)* 1)

$B = (b_0 , \alpha^T)'$ …(23)

U : Square matrix of degree] ((n + 1) * (n + 1)) is written as follows

$$U= \begin{pmatrix} O & O_n^t \\ O_n & \lambda k \end{pmatrix} \quad \ldots(24)$$

As:

Zero vector with degree (n * 1). :O_n

y^*: the vector of the response variable in the kernel regression method (n * 1) and that yi is written as.:

$$y_i = \frac{y_i - \exp(b_0 + k_i'\alpha)}{\exp(b_0 + k_i'\alpha)} + \exp(b_0 + k_i'\alpha) \quad \ldots(24)$$

The estimation of the parameter vector (b0, α) when using the Newton-Ravson method, which determines the values of the estimates in the various stages of the method, is:

$$\begin{pmatrix} \alpha^{(t+1)} \\ b_0^{(t+1)} \end{pmatrix} = \begin{pmatrix} \alpha^{(t)} \\ b_0^{(t)} \end{pmatrix} - \begin{pmatrix} k\, w^{(t)}\, k + \lambda k & k\, \mu^{(t)} \\ \mu^{(t)\prime} k & 1'\, \mu^{(t)} \end{pmatrix}^{-1} \begin{pmatrix} k\, \mu^{(t)} - y + \lambda \alpha^{(t)} \\ 1'\, (\mu^{(t)} - y) \end{pmatrix} \quad \ldots(25)$$

That the estimates of the mean function at the input vector x0 and for the estimated optimum parameter values (b0, α) are:

$\hat{\mu}(x_0)$ =exp ($\hat{b}_0 + k_0^{(t)}\hat{\alpha}$) …(26)

As:

$k_0 = (k(x_1, x_0), \ldots\ldots, k(x_n, x_0))^t$ …(27)

In order to test the penalty parameter (λ) and the parameter of the endodontic function (σ ^ 2) which results in the best preamble, we use for this test forensic (O.C.V) ordinary cross validation.

$$= \frac{1}{n} \sum_{i=1}^{n} \left(\frac{y_i - e^{\widehat{\eta_\theta}(x_i)}}{1 - s_{ii}}\right)^2 \quad \ldots(29)(\theta)\text{O.C.V}$$

As:

sii: the diagonal element of row (i) of matrix S, defined as:

$S = V\ (\ V'\ W\ V + U\ )^{-1}\ V'\ W$ …(28)

When compensating with the average sii which equals ($\frac{1}{n}$tr (s)) in formula (30) we get (g.c.v) Generalized cross validation which is calculated with respect to θ of the parameters my agency:

$$\text{g.c.v } (\theta) = \frac{n \sum_{i=1}^{n} (y_i - e^{\widehat{\eta_\theta}(x_i)})^2}{(n - tr(s))^2} \quad \ldots(29)$$

As:

$\widehat{\eta_\theta}(x_i)$: An estimate of the logarithm μɵ, meaning[$\eta_\theta(x_i) = \log(\mu_\theta)(x_i)$] for each parameter after viewing exclusion (i) according to the(Leave-One-Out method).

2.5 Liu Estimators Method: [12],[5]

It is the second nonparametric method and is used treat of inflation estimated variance parameters of the model. Liu laid the foundations for this method in 1993 when he created it for the linear regression model, then going back to the formula for geometric model given in equation (13):

$Y^* = b_0 + b_1 X_i + u_i$

) Liu (And by adopting the following restriction that he set

$\underline{C}'C = (S\underline{\hat{\beta}} - \underline{\beta}^*)'(S\underline{\hat{\beta}} - \underline{\beta}^*)$ …(30)

AS:

$\underline{C}'W\underline{C} = (Y^* - X\underline{\beta}^*)'\widehat{W}(Y^* - X\underline{\beta}^*) + (s\underline{\hat{\beta}} - \underline{\beta}^*)'(s\underline{\hat{\beta}} - \underline{\beta}^*)$

C′C: the amount of increase in the mean of the weighted error squares when the estimated parameter vector is replaced by the maximum likelihood method ($\underline{\hat{\beta}}$) with the estimated parameter vector according to the Liu method ($\underline{\beta}^*$).

$\underline{\hat{\beta}}$:estimates maximum likelihood when converting the model to a linear model

$\underline{\beta}^*$:: Vector sample parameters estimated by the Liu method

S: bias parameter

After the process of converting the model to linear and placing the constraint, the square of the weighted errors of the researched model is taken with the addition of the constraint and then deriving the result with respect to $\underline{\beta}^*$:as follows:

$\underline{C}'W\underline{C} = (Y^* - X\underline{\beta}^*)'\widehat{W}(Y^* - X\underline{\beta}^*) + (s\underline{\hat{\beta}} - \underline{\beta}^*)'(s\underline{\hat{\beta}} - \underline{\beta}^*)$

$= \underline{Y}^{*'}\widehat{W}\underline{Y}^* - 2\underline{\beta}^* X'\widehat{W}\underline{Y}^* + \underline{\beta}^{*'}X'\widehat{W}X\underline{\beta}^* + S'\underline{\hat{\beta}}'\underline{\hat{\beta}}S - 2S\underline{\hat{\beta}}\underline{\beta}^* + \underline{\beta}^{*'}\underline{\beta}^*$ …(31)

By deriving equation (33) with respect to the parameter vector (β ^ *), we get:

$\frac{\partial \underline{C}'W\underline{C}}{\partial \underline{\beta}^*} = -2X'\widehat{W}\underline{Y}^* + 2X'\widehat{W}X\underline{\beta}^* - 2S\underline{\hat{\beta}} + 2\underline{\beta}^*$ …(32)

When the derivation result is equal to zero, we obtain the Liu estimates for the geometric regression model parameters.

$\underline{\hat{\beta}}_{Liu} = (X'\widehat{W}X + 1)^{-1}(X'\widehat{W}\underline{Y}^* + S\underline{\hat{\beta}})$ …(33)

Since the

$\underline{\hat{\beta}} = \underline{\hat{\beta}}_{ML}$ …(34)

$\underline{\hat{\beta}} = \underline{\hat{\beta}}_{ML} = (X'WX)^{-1}(X'W\underline{Y}^*)$ …(35)

Know in numbered form (32) ,they are estimates maximum likelihood , When converting a geometric regression model to a linear formula

As:

$\left(X'W\underline{Y}^*\right) = (X'WX)\underline{\hat{\beta}}_{ML}$ …(36)

Substituting the value of $\left(X'W\underline{Y}^*\right)$ to its equivalent in the numbered formula (35) we get another form of the liu of the geometric regression model parameters.

$\underline{\hat{\beta}}_{Liu} = [(X'\widehat{W}X + 1)^{-1}\left(X'\widehat{W}X\right)\underline{\beta}_{ML} + S\underline{\hat{\beta}}_{ML}]$

$\underline{\hat{\beta}}_{Liu} = (X'\widehat{W}X + 1)^{-1}\left(X'\widehat{W}X + SI\right)\underline{\hat{\beta}}_{ML}$ …(37)

Standards Comparison: [6],[15] 2-8:

) :AIC (Akaike Information Criterion 1-

$AIC = n\ln\hat{\sigma}_\epsilon^{\,2} + 2M$ ... (38)

) :SBC (Schwartz Bayesian criterion 2-

$\mathrm{SBC} = \mathrm{n}\ln\hat{\sigma}_\epsilon^{\,2} + \mathrm{M}\ln(\mathrm{n})$ ... (39)

) :H-Q (Hannan − Quinn Criterion 3-

$H - Q(M) = ln(\sigma_\epsilon{}^2) + 2MC\ \frac{ln[ln(n)]}{n}\quad ; C > 2$ ... (40 ∗)

AS :

$\hat{\sigma}_{\epsilon}^{\ 2} = \frac{\sum_{t=0}^{n}(e_i - \hat{e}_i)^2}{n}$

n: represents the number of views.
M: number of parameters of the chosen model or model rank.
C: fixed.

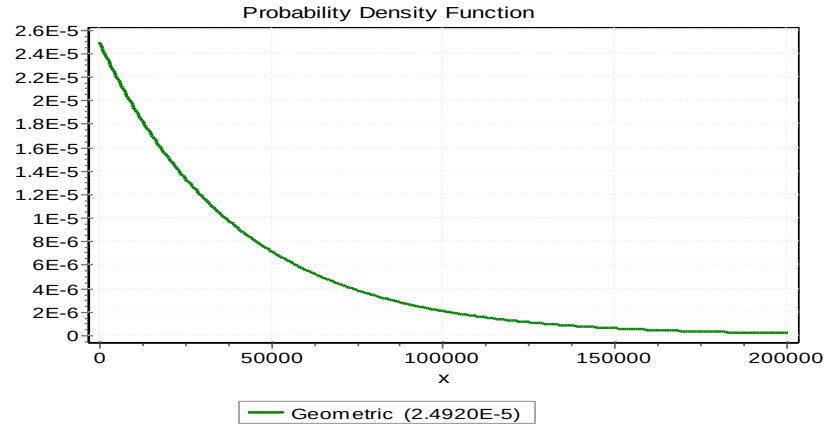
3-The applied side.

3-1 :Description and definition of the study sample:

The annual secondary student preparation data in the holy governorate of Karbala was relied on for the period of time ((1969-2019) for the geometric regression equation, and the dependent variable (Y) represented the preparation of secondary students during time and the independent variable(X) time (years).

:Appropriate statistical distribution:3-2

To find out the statistical distribution appropriate to the preparation of secondary students, a goodness of fit test was used for the data through the Easy Fit statistical program. The results showed that the data follows the geometric distribution with parameters($\theta = 2.4920E - 5$) ana the value (p-value=0.000).



Form (1) probability density function for the geometric distribution

3-3: Statistical analysis of data:

The data were analyzed statistically using the statistical program (Gretl 1.9.11).

First: Estimate the geometric regression equation using the kernel regression method and the Leo agency method:

1-The estimated formula for the geometric regression equation using the kernel regression method is:

$\ln y = 9.44278 + 0.0368146\ x$

2-The estimated formula for the geometric regression equation using the Leo method is:

$lny = 9.29892 + 0.0429313\ x$

Second: The test of the significance of the putative linear relationship 1-Linear relationship significance test for the estimated engineering regression equation using the kernel method. To find out the significance of the linear relationship, we test the following hypothesis:

$H_0: B_1 = 0$

$H_1: B_2 \neq 0$

Through the numbered analysis of variance table (2) we obtain the value of the test (F) that determines the nature of the relationship between the dependent variable and the independent variable

Table (1) analysis of variance

	Sum of squares	df	Mean square
Regression	14.1122	1	14.1122
Residual	0.27484	48	0.00572583
Total	14.387	49	0.293613

R^2 = 14.1122 / 14.387 = 0.980897
F(1, 48) = 14.1122 / 0.00572583 = 2464.65 [p-value 6.45e-043]

Looking at Table (1), we notice that the test value is ((F = 2464.65) and its probability value [p-value = 6.45e-043] It is less than the level of significance (0.05), we accept the alternative hypothesis which states that the time variable exerts its effect on the student numbers variable and the percentage (98%).

2- Test the significance of linear relationship of the estimated geometric regression equation using the Liu method.

To find out the significance of the linear relationship, we test the following hypothesis:

$H_0: B_1 = 0$

$H_1: B_2 \neq 0$

Through the numbered analysis of variance table (3) we obtain the value of the test (F) that determines the nature of the relationship between the dependent variable and the independent variable.

Table (2) analysis of variance

	Sum of squares	df	Mean square
Regression	19.1912	1	19.1912
Residual	0.835683	48	0.0174101
Total	20.0269	49	0.408712
R^2 = 19.1912 / 20.0269 = 0.958272			
F(1, 48) = 19.1912 / 0.0174101 = 1102.31 [p-value 9.08e-035]			

Looking at Table (2), we notice that the test value is ((F = 1102.31) and its probability value[p-value = 9.08e-035] It is less than the level of significance (0.05), we accept the alternative hypothesis which states that the time variable exerts its effect on the variable of student numbers and the percentage (95%).

3-4 Standards Comparison:

After the geometric regression models have been estimated and the linear relationship is significant, the differentiation criteria are used to choose the method that best achieves the agency model:

Table (3) Standards Comparison

	AIC	BIC	H-Q
Liu Method	-58.68260	-54.85855	-57.22638
Kernel Regresion Method	-114.2857	-110.4616	-112.8294

By looking at Table (3), we notice that the kernel regression method is preferable because it has the smallest differentiation criteria, compared to the Leo method.

3-5: Prediction:

The number of secondary students can be predicted for the holy city of Karbala for the future time period (2021-2030) using the estimated geometric regression model according to the Kernel method based on time series data, Table (1).

Table (4) Predictive Values for Preparing Secondary Stage Students for the Duration (2030-2021)

Years	2021	2022	2023	2024	2025
Predictive Values	82481	85574	88783	92112	95567
Years	2026	2027	2028	2029	2030
Predictive Values	99150	102863	106726	110729	114881

4. Result and recommendations:

1- The secondary student preparation data has appeared subject to the geometric distribution.
2- The significance of the estimated regression equation using the kernel regression method.
3- Significance of the estimated regression equation using the Liu method.
4- The preference of the kernel regression method is preferable to the Leo method, since the first method has the lowest Standards Comparison.
5-Depending on the values predicted by the geometric regression model, it was noted that there has been a decrease in the number of students from the last sex previous years.
6- Using other methods to estimate the geometric regression equation to arrive at the best prediction model.
7- Making use of the research findings and adopting them to prepare future plans from the relevant authorities.
8- Mtudying the decrease in the number of future students.

The KR-Elliptic Curve Public Key Cryptosystem

The KR –Elliptic Curve Public Key Cryptosystem

Karrar Taher R. Aljamaly and Ruma Kareem K. Ajeena

Mathematics Department, Education College for Pure Sciences, University of Babylon, Iraq

E-mail: ruma.usm@gmail.com

Abstract. The connection between some fundamental mathematical problems in number theory with cryptography has been done in this work. A new version of the elliptic curve public key cryptosystem (ECPKC) has been proposed by Karrar Taher and Ruma Ajeena. Their main idea is to design this cryptosystem focusses on generating the elliptic curve group, its order divides the Euler phi function that is computed securely based on two large primes. Faster and more secure computations to generate the keys, encryption and decryption processes, on the KR-ECPK algorithm are discussed. In comparing with other algorithms like RSA and ElGamal public key cryptosystem (EEPKC), the KR-ECPKC considers as an efficient algorithm. So, the KR-ECPKC is more appropriate for elliptic curve cryptographic applications.

1. Introduction

The elliptic curve cryptography (ECC) is more interested for many researchers, because it has employed in different applications such mobile devices, wireless sensor, network, image encryption and others [1,2,3]. The ECC has keys with small size that allows to be much efficient in comparing to other public key cryptosystems like RSA [4].

The RSA cryptosystem is proposed Rivest, R.L., et al, in 1978 through presenting a public key cryptosystem which was depended on the integer factorization problem, that factors a composite number into two large primes [4]. In 1985 Miller introduced proposed the Diffie-Hellman key exchange protocol based on elliptic curves [5]. In 1987, Koblitz proposed elliptic curve ElGamal public key cryptosystem [6]. In 2000, Neal Koblitz introduced the state of elliptic curve cryptography, he presented a survey about the elliptic curve cryptosystems [7].

In this work, we are looking for a small size key, faster and secure computation. So, our work focusses on the proposed new version of elliptic curve public key cryptosystem. That has faster computations of the encryption and decryption processes in comparing with other elliptic curve cryptosystems.

The outline of this work includes Section 2, which discussed the RSA cryptosystem in its first part. And in the second part, another public key cryptosystem which depended on elliptic curves is explained, this cryptosystem is called ElGamal elliptic public key cryptosystem (EEPKC). In section 3, a new version of the elliptic curve cryptosystem is proposed. Section 4, discusses a study case of the proposed EC-Cryptosystem. Some computational results of the proposed EC-cryptosystem are explained in Section 5. Section 6, presents the comparison on the proposed EC-cryptosystem, RSA and EEPKC. The security considerations of the proposed EC-cryptosystem are determined in Section 7. Finally, Section 8, displays the conclusions.

2. Mathematical Background

The RSA cryptosystem proposed in 1978 by R. L. Rivest, A. Shamir, and L. Adleman [4]. A public key on the RSA cryptosystem is a pair of integers (n,e), where n is a product of two secret primes p and q and e is an integer satisfying gcd(e, φ)=1, with $\varphi = (p-1)(q-1)$ is Euler phi function. Whereas, a private key d is an integer satisfying $ed \equiv 1 \pmod{\varphi}$. The ciphertext c of a plaintext m is computed by $c = m^e \pmod{n}$. The original message can be recovered through decryption process that is computed by $m = c^d \pmod{n}$.

On the other hand, the ElGamal elliptic curve public key cryptosystem (EECPKC) is proposed by ElGamal in 1987 [6]. The users, sender and receiver agree to choose a prime p, an elliptic curve equation $E : y^2 = x^3 + ax = +b \pmod{p}$ [8,9] and to determine a generator elliptic point P as the public parameters. The receiver chooses a random integer d as his/her secret key and computes his/her public key dP. The sender selects a message M as an elliptic point in $E(F_p)$ and encrypt it by a pair (C_1,C_2), where $C_1 = eP$ and $C_2 = M + e(dP)$. The receiver decrypts the ciphertext (C_1,C_2) through computing $C_2 - dC_1 = M + e(dP) - d(eP) = M$.

3. The KR-Elliptic Curve Cryptosystem

The encryption process is done as follows. A plaintext m selected and represented as elliptic point in $E(F_p)$ [10]. Then a message M is encrypted by $C = e'M$, where e' is computed by $e' \equiv e \pmod{N}$, with N is an order of M. The ciphertext C considers as a scalar multiplication, which can be computed by ISD method [11,12]. Algorithm (3.2.1) is employed to compute the ciphertext C.

3.1. The KR-Elliptic Curve Cryptosystem: Keys Generation Process

First, a set of the points on an elliptic curve group $(E(F_p),+_E)$ is computed. The order $\#E(F_p)$ of a group $(E(F_p),+_E)$ should divide a positive integer n, where $n = (q-1)(t-1)$ with q and t are two large primes that are selected secretly by a first user to compute his/her private key n. The public key e is selected as an integer from the range $[2, n-1]$ such that $\gcd(e,n) = 1$. So, the public and private keys are e and n respectively. Algorithm (3.1.1), is used to generate the keys of the KR-EC cryptosystem.

Algorithm 3.1.1. The KR-EC Cryptosystem: Keys Generation Process.

INPUT: The large prims (q,t).

OUTPUT: The set of elliptic curve points and public key e.

1. Select $a,b \in [1,n-1]$ are coefficients of E.
2. Compute $n = (q-1)(t-1)$.
3. Select randomly $e \in [2,n-1]$
4. If $\gcd(e,n) = 1$ then
5. Return e
6. Else
7. Stop and go to step (3).
8. End if
9. Compute the elliptic curve set $E(F_p)$.
10. Compute the order $\#E(F_p) = h$ of $E(F_p)$.
11. If $h \mid n$ then
12. Return the set $E(F_p)$

13. Else
14. Stop and go to step (1).
15. End if
16. Return $(n, e, E(F_p))$.

3.2. The KR-Elliptic Curve Cryptosystem: Encryption Process

The encryption process is done as follows. A plaintext *m* selected and represented as elliptic point in $E(F_p)$ [10]. Then a message *M* is encrypted by $C = e'M$, where e' is computed by $e' \equiv e \pmod{N}$, with *N* is an order of *M*. The ciphertext *C* considers as a scalar multiplication, which can be computed by ISD method [11,12]. Algorithm (3.2.1) is employed to compute the ciphertext *C*.

Algorithm 3.2.1. The KR-EC Cryptosystem: Encryption Process

INPUT: A set $E(F_p)$ of elliptic points, a public key *e* and plaintext *m*.

OUTPUT: The ciphertext *C*.

1. Convert a message *m* as an elliptic point $M \in E(F_p)$ [10].
2. Compute the order *N* of a point *M*.
3. Compute $e' \equiv e \pmod{N}$.
4. Compute $C = e'M$.
5. Return *C*.

3.3. The KR-Elliptic Curve Cryptosystem: Decryption Process

Upon receiving the ciphertext to the first user, he/she wants to decrypt the ciphertext and recover the original message. First, he/she computes the key *d* secretly, where $d \in [2, n-1]$ and $ed = 1 \pmod{n}$. Then d' is computed by $d' \equiv d \pmod{N}$ with *N* is an order of the *C* that is computed as an elliptic curve point. The original message is recovered by $d'C = M$. The decryption process is proved mathematically in following proposition.

Proposition 3.3.1. The decryption process of KR-EC cryptosystem takes the expression $M = d'C$.

Proof.

$d'C = d'(e'M)$, since $C = e'M$.

$= deM$

$= (rn + 1)M$ such that *r* is a positive integer, since $ed = 1 \pmod{n}$.

$= rnM + M$

$= r(sN)M + M$ such that *s* is a positive integer and *N* the order of *M* that is ($NM = O_E$), since every order of elliptic point divide *n*.

$= rs(NM) + M$

$= rs(O_E) + M$

$= M$. ■

For the computational results to recover a message *M*, one can use Algorithm (3.3.2).

Algorithm 3.3.2. The KR-EC Cryptosystem: Decryption Process.

INPUT: A set $E(F_p)$ of elliptic points, a public key *e*, a privet key *n* and the ciphertext *C*.

OUTPUT: A key *d* and a plaintext *m*.

1. Choose randomly $d \in [2, n-1]$

2. If $ed = 1(\mathrm{mod}\, n)$ then
3. Return *d*
4. Else
5. Stop and go to step (1).
6. End if
7. Compute the order *N* of a point *C* that is a ciphertext.
8. Compute $d' \equiv d\,(\mathrm{mod}\, N)$.
9. Compute $d'C = M$.
10. Convert *M* into *m* [10].
11. Return *m*.

4. The Study Case on the KR-EC Cryptosystem.

The keys, namely public and private are generated first. A prime $p = 8123$ is chosen and the elliptic points set $E(F_{8123})$ is determined by supposing the elliptic curve $E: y^2 = x^3 + 5x + 13$ as the public parameters. The set

$E(F_{8123}) = \{(1,1548),(1,6575),(3,3067),(3,5056),(4,6052),(4,2071),...,(8122,5994),(8122,2129),O_E\}$.

The $\#E(F_{8123}) = 8144$ such that $8144 \mid n$, where *n* is a private key for the first user. The private key is computed by $n = (q-1)(t-1) = 12123438 \cdot 31423268 = 3809574206353584$, where $q = 12123439$ and $t = 314232169$ are two large primes that are selected secretly. The public key *e* is selected randomly from the range [2,3809574206353583] and

$$\gcd(e, n) = \gcd(12326106299, 3809574206353584) = 1.$$

So, the public and private keys are $e = 12326106299$ and $n = 3809574206353584$ respectively. Now for encryption process, suppose second user chooses a message $M = (1000, 5149)$ which is an elliptic point in $E(F_{8123})$. The order of a point *M* is 4072, namely

$$4072M = 4072(1000, 5149) = O_E.$$

He/She computes $e' = 3491$ through computing $e' \equiv e \bmod(4072)$. The ciphertext *C* is computed as a scalar multiplication $C = e'M = 3491(1000, 5149) = (5375, 4448)$. The ciphertext $C = (5375, 4448)$ will be sent to the first user. After receiving the ciphertext *C* into the first user, he/she computes $d = 618131$ such that

$$\mathrm{ed(modn)} = 12326106299 \times 618131 \bmod(3809574206353584) = 7619148412707169 \bmod(3809574206353584) = 1.$$

The order of a ciphertext *C* which is considered as an elliptic curve point is computed to be $N = 4072$, since

$$4072C = 4072(5375, 4448) = O_E.$$

The parameter $d' = 3259$ is computed, where $d' \equiv d \bmod(4072)$. First user computes a scalar multiplication

$$d'C = 3259(5375, 4448) = (1000, 5149) = M.$$

5. The Computational Results on the KR-EC Cryptosystem.

Some simple computational results about the KR-EC cryptosystem have been done. The experimental samples with different values of a primes *q* and *t* are chosen The computational results to generate the keys, encryption and decryption processes are shown in Tables (1), (2) and (3) respectively.

Table 1. The experimental results of the KR-EC cryptosystem: key generation process.

6. Comparison on the KR-EC, RSA and EEPK Cryptosystems

By using the proposed KR-EC cryptosystem, there is no problem to choose the small primes q and t for computing $n=(q-1)(t-1)$, since n is a private key. In comparing with that, the RSA public key cryptosystem needs the choice of the large primes for increasing the security. The public key generation process in elliptic curve ElGamal public key cryptosystem (EC-EPKC) requires more computations to solve the discrete logarithm problem (DLP) comparing with the new version KR-EC cryptosystem that is proposed to choose a public key as a number in the range $[2,n-1]$ with $\gcd(e,n)=1$. Also, computing a public key on the EC-EPKC requires finding the generator point on elliptic curve group in comparing to the KR-EC cryptosystem which is not required that.

As well as, the proposed version KR-EC cryptosystem is considered faster public key algorithm in compare with EC-EPKC, since on the KR-EC cryptosystem, the encryption and decryption processes need computing only the scalar multiplication operation while on the EC-EPKC requires for these processes computing the scalar multiplication and addition operations, so the last cryptosystem needs extra computations.

7. The Security Considerations on Proposed Public Key Cryptosystems

The security of the proposed encryption scheme determines through some main points. The first one is about the difficulty of solving the Elliptic Curve Discrete Logarithm Problem (ECLP) [13]. The ECLP, means computing the value of k that lies in the range [1, z-1] and satisfies the relation $kP = Q$, for given P and Q which are elliptic curve points and z is a prime order of P. The second one is the hardest to find the private key d others, where e is a public key such that $ed=1(\mathrm{mod}\,n)$ because n is a secret key. The element d here represents the inverse element of e modulo n, and since n is computed securtly, so it is more difficult to compute the value of d modulo n.

8. Conclusion

This work presented a new version of the elliptic curve public key cryptosystem which is called the KR-EC public key cryptosystem. It depended on the hardness computation of the elliptic curve discrete logarithm problem (ECDLP) and some mathematical computation problems from the number theory. On the proposed KR-EC public key cryptosystem, faster computations to generate the keys, encryption and decryption processes are done. The security of the KR-EC public key cryptosystem is determined based on the difficulty of computing the ECDLP and selecting the primes to compute the Euler phi function secretly. So, the KR-EC public key cryptosystem considers as a brilliant insight for elliptic curve encryption schemes.

Tuning Parameters of ANFIS Model Using Chaotic Particle Swarm Optimization Algorithm

Tuning Parameters of ANFIS Model Using Chaotic Particle Swarm Optimization Algorithm

Fatima Hashim Najim and Omar Saber Qasim

Department of Mathematics, University of Mosul, Mosul, Iraq

E-mail: fatima.csp103@student.uomosul.edu.iq

Abstract: In recent years, researchers have worked to find multiple methods to overcome the classification problems they encountered. In this paper, both the Chaotic Particle Swarm Optimization (CPSO) algorithm are connected with the Adaptive Fuzzy Inference System (AFIS) model, through two stages, the first stage, CPSO algorithm is used to tune parameters of the fuzzy inference system model. In the second stage, the fuzzy inference system model is constructed according to the optimum parameters that are found by the CPSO algorithm. The proposed CPSO-AFIS algorithm demonstrated efficacy and efficiency compared to the standard algorithm Adaptive Neuro Fuzzy Inference System (ANFIS).

1. Introduction:

When we classify a set of data using modern methods, we expect to obtain better results according to the available classifiers, and the examiner may not be able to use the classification in which he is not an expert, for example training the accuracy of parameters, and to obtain more accurate parameters, this is limited to use the expertise of the expert. Thus, there can be no complete realization that it is the best possible [1, 2].

Both the fuzzy system and the artificial neural network are the focus of researchers' attention, so the researchers worked to combine these two systems together to get one system called the Adaptive Nervous System for Fuzzy Inference (ANFIS). They obtained a system with distinctive characteristics that help overcome many of the problems (flexibility, speed, adaptability) that existed in both systems, so, they got better performance than the expert fog systems and the artificial neural network [3].

The focus of the researchers in (ANFIS) was to find a model capable of obtaining more accurate results through parameter training [4]. In spite of this improvement, sometimes we find there is a weak ability to find the best efficiency. Therefore, the swarm algorithms were used to make the system more efficient and accurate [5, 6].

The remnant of this paper is organized as follows: The chaotic map is presented in Section 2. The PSO in Section 3. ANFIS is presented in Section 4. The Proposed CPSO-AFIS algorithm is explained in Section 5. Section 6 covers the Experimental Results. Finally, in section 7, the conclusions are mentioned.

2. Chaotic Map:

Chaos theory used the mathematical approaches to improve both exploration and exploitation during the search for the optimal solution. The chaos is closely related to the study of the chaotic dynamic systems that are highly sensitive to the initial conditions, meaning that any small change in the elementary society

can have a major impact on the final results. Chaotic have random behavior, but providing chaotic behavior does not necessarily need randomness، and deterministic systems can also exhibit chaotic behavior without the need for randomness [2, 7].

2.1 Sine Map

The mathematical formula of this map is described in the following [8]:

$$X_{n+1} = \frac{a}{4} \operatorname{Sin}(\pi X_n) \quad (1)$$

where $0 < a \leq 4$

3. Particle swarm optimization (PSO)

The PSO algorithm is a simulation of the behavior of groups of fish, insects and birds that fly in search of food through co-operation between group members, which was applied by Kennedy and Eberhardt 1995 [9]. The algorithm relies on a set of random values called particles. Each particle in the PSO is linked to the velocity and location of the object and can be modified. These particles move within the search space and the original algorithm of PSO is described as follows [10, 11]:

$$v_{id} = v_{id} + c1 \text{ rand } () (p_{id} - x_{id}) + c2 \text{ rand } ()(p_{gd} - x_{id}) \quad (2)$$

$$x_{id} = x_{id} + v_{id} \quad (3)$$

where c_1 and c_2 are positive constants in Eq.(2), and rand () and rand () are two random functions (random numbers) in the range $[0,1]$, $X_i = (x_{i1}, x_{i2}, \ldots, x_{iD})$ represents the ith particle , $P_i = (p_{i1}, p_{i2}, \ldots, p_{iD})$ represents the best previous position (the position giving the best fitness value) of the ith particle.

The symbol g in Eq.(2) represents the index of the best particle among all the particles in the population, $V_i = (v_{i1}, v_{i2}, \ldots, v_{iD})$ represents the rate of the position change (velocity) for particle i. The Eq. (2) explains how the velocity of the particles (birds, fish, insects, etc.) is updated dynamically and that Eq.(3) describes how the site is updated for particles [12, 13].

4. The Adaptive Neural Fuzzy Inference System (ANFIS)

Neural networks play an essential role when there is a sufficient number of inputs to conduct the training without prior knowledge of the nature of the entered data. As for fuzzy systems, there must be a full knowledge of the rules on which the problem is classified as it is represented by (IF-THEN) rules, which is the phrase for conditional statements expressed in the formula [14]:

IF X then Y, where both X and Y are fuzzy sets.

The idea of ANFIS aims to integrate a neural network system with an adaptive fuzzy logic system, that is, we get a mysterious nervous system that combines the features of the neural network and the mysterious inference of the Sugeno type, which was developed in the early 1990s by Jean in order to reap the benefits available in both systems at the same time [5].

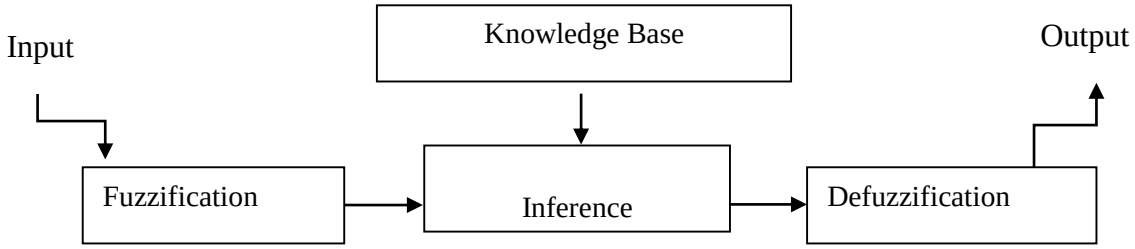

Figure 1. The adaptation ANFIS to conduct learning and training

If we conduct the fuzzing on the obvious input variables, then can apply the rules to them, and then remove the fuzzing with an inverse process to get real values [15].

The general structure of ANFIS for Sugeno model (first rank) can be defined as :

$$\text{IF } X_n \text{ is } A_i \text{ AND } Y_n \text{ is } B_i \text{ THEN } F = P_i X_1 + q_i X_n + r_i \quad (4)$$

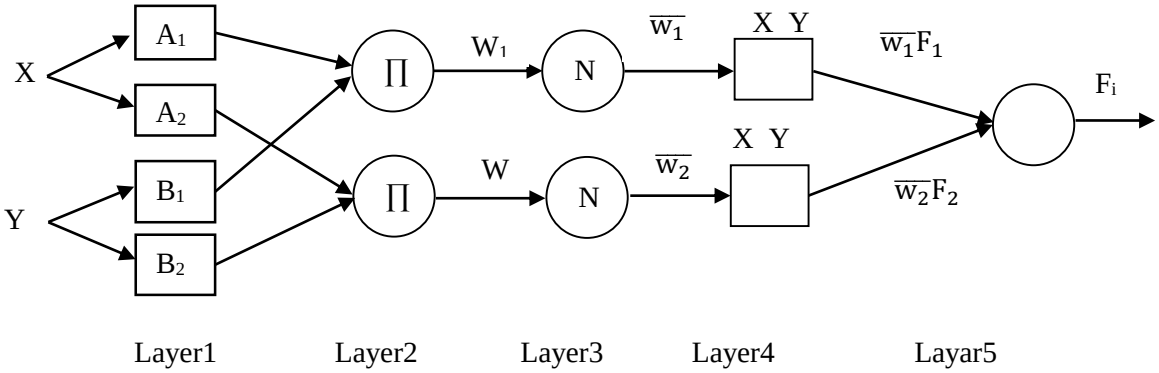

Figure 2. The general structure of ANFIS

The first layer represents the process of fuzzing and determining the degree of membership for each entry. Usually, the organic grades within the first cycle are not appropriate and the reason for this is the random representation of these membership functions until the adjustment process is carried out, where these degrees are represented as follows [16]:

$$Oi1 = \mu A_i(X), \mu B_i(Y) \quad (5)$$

The second layer is the nodes that are not adaptive as the rules are applied to them:

$$Oi٢ = \mu A_i(X_1) * \mu B_i(Y_n) \quad (6)$$

The third layer, the excitation force on neurons is calculated through the normalization process and is as follows [17]:

$$\overline{w_i} = \frac{w_i}{\sum w_i} \quad (7)$$

This represents the output for the third layer and is symbolized by O_i^3.

The fourth layer in this layer, the fuzzing process is reversed, meaning results are easy to read and understand Where this process takes place as follows [18]:

$$O_i^4 = Y_i = \overline{w_i} F_i = \overline{w_i}(p_i X_1 + q_i X_2 + r_i) \quad (8)$$

where pi, qi, and ri are the parameters of the model in a given order because they deal with the part that was then in the ambiguity area.

The fifth layer This layer represents the final output of the system (ANFIS) as it consists of one node and represents the sum of the outputs of the nodes in the previous layers. The calculation is as follows:

$$O_i^5 = \sum_i y_i = \sum_i \overline{w_i} F_i = \sum_i \overline{w_i}(p_i X_1 + q_i X_2 + r_i) \quad (9)$$

The learning algorithm in ANFIS uses a hybrid learning, as it combines the two methods of rapid regression and the method of estimating the least squares, and the training in each epoch goes through two phases: the forward direction phase and the back direction phase [18, 19].

5. The Proposed Algorithm CPSO-AFIS

The proposed CPSO-AFIS method consists of two basic stages. In the first stage, the Chaotic Particle Swarm Optimization Algorithm (CPSO) is used to determine the optimum parameters of the Fuzzy Inference System (FIS) in the Sugeno model. In the second stage, a FIS model is created according to the optimal parameters that were found by the CPSO algorithm, where these optimal parameters are entered into the inference system and the ideal model is formed according to the dataset used. The proposed CPSO-AFIS method has been tested on three different datasets and classified according to the Mean Squared Error (MSE) criteria.

Algorithm1: Steps of the proposed CPSO-AFIS algorithm.

Step1: Set the initial parameters of FIS and PSO algorithm.

Step2: Initialization a chaotic sine map with the initial point (x=0.7).

Step3: Create FIS of Sugeno model using optional parameters.

Step 4: Set the initial velocities and positions using, Eq. (2) and Eq. (3)

Step 5: Evaluate dataset by fitness function.

Step 6: Set iteration i from 1 to max of iteration.

Step 7: Update velocity and position according to Eq. (2) and Eq. (3).

Step 8: When i≤ Max_iteration stop satisfied and return get the best parameters of FS.

Step 9: Insertion of the optimal parameters of FIS into the Sugeno model.

Step 10: Calculate the MSE criterion for the proposed CPSO-AFIS method.

6. Experimental Results

The proposed algorithm CPSO-AFIS is evaluated, and its interest is compared with the ANFIS model. In order to verify the effectiveness of the CPSO-AFIS algorithm for classification problems, we selected 3 different classification datasets from the literature. These datasets were obtained from the UCI repository [20]. Table 1 shows the comprehensive description of data sets.

Table 1: Description of the used datasets**.**

Dataset	# Samples	# Features
Data1=Iris	150	4
Data2=Engine	1199	2
Data3=Thalassemia	150	10

The training and testing dataset for the CPSO-AFIS algorithm, achieved the best MSE, for instance, in Data1, the MSE of the testing dataset is 4.2444e-2 by the FMI-BPSO which is lower than 5.1314e-2 by ANFIS.

Table 2: The MSE of training and testing for datasets.

Datasets	Methods	MSE of Training	MSE of Testing
Data1	CPSO-AFIS	3.5362e-2	4.2444e-2
	ANFIS	4.5146e-2	5.1314e-2
Data2	CPSO-AFIS	3.9281e-4	3.7042e-4
	ANFIS	4.6159e-4	4.6821e-4
Data3	CPSO-AFIS	8.0337e-3	7.5253e-3
	ANFIS	8.4832e-3	7.547e-3

The execution comparison shows that, compared to the ANFIS model, the proposed algorithm, CPSO-AFIS, has an obvious advantage in terms of MSE of the classification and the ANFIS is worse than CPSO-AFIS through the three datasets.

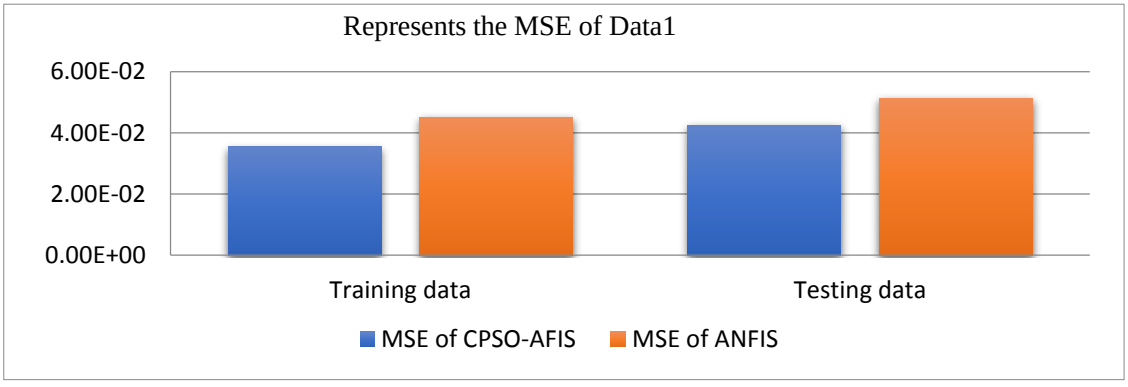

Figure 3. Represents the comparison of MSE between CPSO-AFIS & ANFIS in Data1.

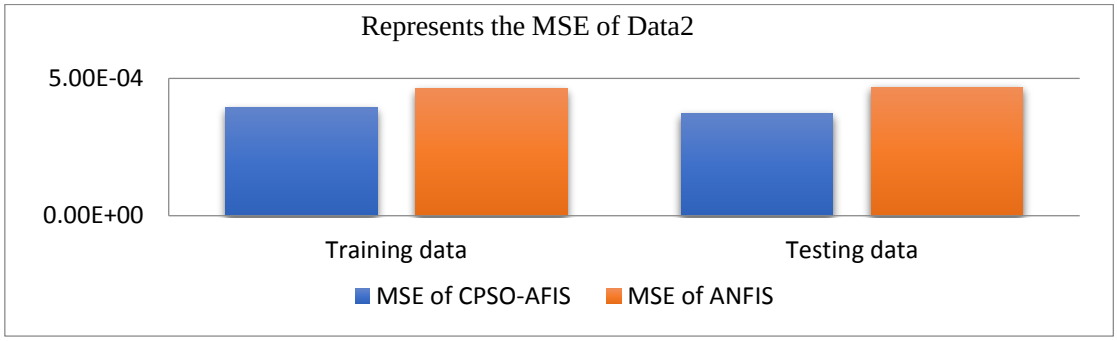

Figure 4. Represents the comparison of MSE between CPSO-AFIS & ANFIS in Data2.

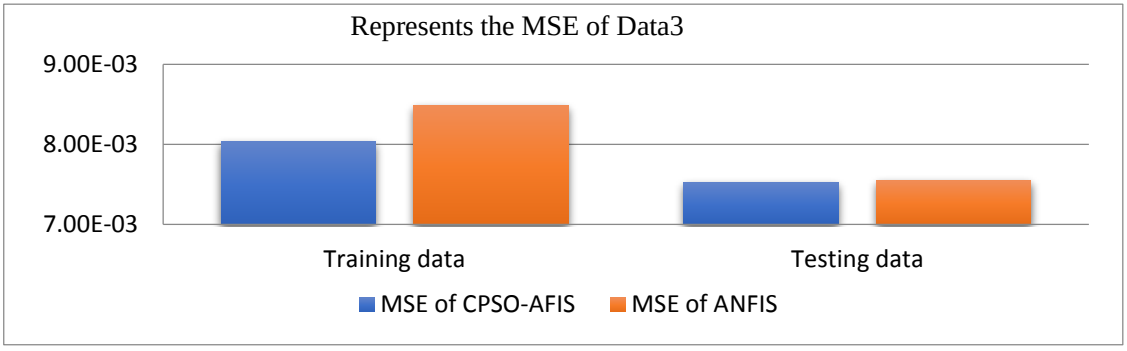

Figure 5. Represents the comparison of MSE between CPSO-AFIS & ANFIS in Data3.

7. Conclusion

In this paper, the CPSO-AFIS method was proposed between the chaotic Particle Swarm Optimization Algorithm (CPSO) of type Sine map and Fuzzy Inference System (FIS) of type Sugeno model to improve the classification performance of the datasets in Table 1. The results of the proposed CPSO-AFIS method were compared with the results of ANFIS through the Table2 and Figures (3-5) and the experimental results from the datasets in Table2 indicate that the proposed CPSO-AFIS method has a classification performance that is higher than the ANFIS through MSE criteria.

Solve differential equations via a hybrid method between homotopy analytical method and sine cosine optimization algorithm

Solve differential equations via a hybrid method between homotopy analytical method and sine cosine optimization algorithm

Mostafa raed najeeb , Omar Saber Qasim and Ahmed Entesar

Department of Mathematics, College of Computer Sciences and Mathematics, University of Mosul, Iraq

E-mail: mostafa.csp115@student.uomosul.edu.iq

Abstract. In this paper, ordinary differential equations (ODEs) of two types, linear and non-linear will be solved by using the homotopy analytical method (HAM), and the sine cosine algorithm (SCA) will be used to modify the parameter h and obtain a better approximate solution than what was in the previous method HAM. The suggested method, HAM-SCA, covers a solution that reveals the reliability and the efficiency correspondingly to the default method HAM by computing the maximum absolute errors (MAE) and mean square error (MSE).

1. Introduction

All-natural, physical, engineering, and other phenomena are expressed by DEs (linear and nonlinear), these equations differential in the method of solution, a few of them can be solved directly, so it was necessary to use approximate methods to address problems and arrive at the solution, as the HAM is one of these methods [1].

HAM is the method that the world Liao Shijun discovered in 1992 [2, 3], he relied on using the homotopic method to obtain a convergent series solution (convergent series) for various types of equations whether linear or non-linear equations, DEs, integral equations, and other types of equations, the HAM method describes a kind of deformation or disparity in mathematical, for example, a circle can be deformed continuously to a square or an ellipse, as well as a cup of coffee, can be deformed continuously into a football [1, 4], in general, the HAM connects objects different has the same properties, one of what distinguishes this method is that it is free of any)small or large(concrete parameter, as well as provides appropriate methods to guarantee convergence in the series of solutions even if the non-linear boundary is complex, and it gives us the privilege in choosing the type of equation for sub-problems, the initial guess, and the basic function.

SCA is one of the swarm algorithms invented by the scientist Sidali Mergalieli, used to solve optimization problems and obtain the best solution, based on the principle of exploration and exploitation as it creates and searches many random solutions depending on the properties of the sine and cosine and switches between them according to a specific condition. [5-7].

We can represent the algorithm in the following form

$$w_n^{v+1} = w_n^v + d_1 \sin(d_2)|d_3\, p_n^v - \, w_n^v| \quad (1)$$

$$w_n^{v+1} = w_n^v + d_1 \cos(d_2)|d_3\, p_n^v - \, w_n^v| \quad (2)$$

As w_n^v is the current subject of research, in $n-th$ dimension at $v-th$ iteration, and d_1, d_2, d_3, d_4 are random numbers, and p_n is the location of the destination point in the n-th dimension, and || is the absolute value [6]. We can combine the two previous equations as follows.

$$w_n^{v+1} = \begin{cases} w_n^v + d_1 \sin(d_2)|d_3\, p_n^v - w_n^v|, & d_4 < 0.5 \\ w_n^v + d_1 \cos(d_2)|d_3\, p_n^v - w_n^v|, & d_4 \geq 0.5 \end{cases} \quad (3)$$

Where d_4 is arbitrary within the closed interval [0,1].
The parameter d_1 specifies the next position (in which direction the move will be) by the following law:

$$d_1 = m - t\,\frac{m}{T} \quad (4)$$

Where t is the value of the current frequency, T is the ultimate number of iterations, and m is a mass constant, which can be either the distance between solutions, the destination or outwards and, the parameter $d2$ assigns how unlikely the movement must be pointed or outward, the $d3$ parameter specifies a random weight for a $(d3 > 1)$ random check, or $(d3 < 1)$ reduces the focus for the destination effect when specifying a distance.

SCA named after that name for its use of the sine and cosine functions completely in its general form, as it changes and modifies the range of the sine and cosine functions each time to determine a new search site, whether it is in the space or outside the space or if it is between it and another solution, then a value is chosen random $d2$ for a certain period, this mechanism clarifies the true meaning of the processes of exploration and exploitation, and this algorithm makes the correct selection and reconciliation between exploration and exploitation to reach the goal [8,9], which is through the convergence of solutions as shown in the Figure (1).

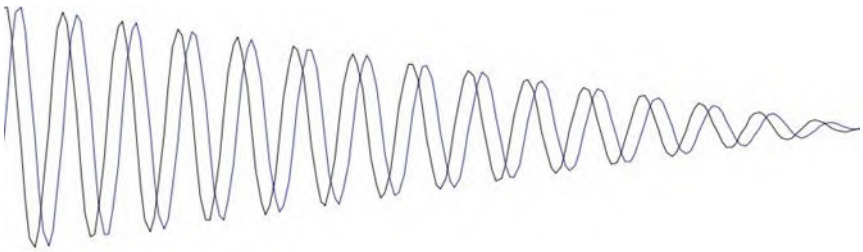

Figure 1: Demonstrates the convergence of solutions in SCA

2. General Concepts

In this part, will mention some important definitions in this paper

2.1 Definition

The maximum absolute errors MAE is determined by the following formula

$$\|z_{Exact}(y) - \propto_i (y)\|_\infty = \max_{a \leq x \leq b} \{|z_{Exact}(y) - \propto_i (y)|\} \quad (5)$$

Here $\propto_i (y), i = 1,2, \ldots$ are the successive estimates of the solution $z\,(y)$ [4].

2.2 Definition

Let's have the vector $\vec{x_i}$ where $i = 1,2, \ldots$, the MSE is a sum the square of the exact solution Exact (y_i) minus the approximate solution divided by the number of iterations k which is as follows [10]

$$MSE = \frac{1}{k}\sum_{i=1}^{k} (Exact\,(y_i) - \emptyset(y_i))^2 \quad (6)$$

2.3 Definition

The MAE is defined by the following formula

$\frac{1}{k}\sum_{i=1}^{k}|Exact\ (y_i) - \emptyset(y_i)|\ , i = 1,2, \ldots$ (7)

Which represents the absolute value of the sum of the product of subtracting the real value from the approximate value divided by the number of iterations [11].

2.4 Adomian Polynomials

Will use the Adomian method to solve the non-linear terms from the ordinary DEs [12]. When $f(u) = u^2$ [13, 14].

Can use the Adomian method to extend the nonlinear term to the $f(u) = u^2$ document using

$x_0 = u_0^2$
$x_1 = 2u_0u_1$
$x_2 = 2u_0u_2 + u_1^2$
$x_3 = 2u_0u_3 + 2u_1u_2$
$x_4 = 2u_0u_4 + 2u_1u_3 + u_2^2$
$x_5 = 2u_0u_5 + 2u_1u_4 + 2u_2u_3,$
$\vdots$
$x_n = \sum_{i=0}^{n} u_i\, u_{n-i}\ , \quad n \geq i, \quad n = 0, 1, 2, \cdots$

When $f(u) = uu'$ [13,14]

$x_0 = u_0\, u_0''$
$x_1 = u_1\, u_0'' + u_0\, u_1''$
$x_2 = u_2\, u_0'' + u_1\, u_1'' + u_0\, u_2''$
$x_3 = u_3\, u_0'' + u_2\, u_1'' + u_1\, u_2'' + u_0\, u_3''$
$x_4 = u_4\, u_0'' + u_3\, u_1'' + u_2\, u_2'' + u_1\, u_3'' + u_0\, u_4''$
$x_5 = u_5\, u_0'' + u_4\, u_1'' + u_3\, u_2'' + u_2\, u_3'' + u_1\, u_4'' + u_0\, u_5''$
$\vdots$
$x_n = \sum_{i=0}^{n} u_i\, u_{n-i}''\ , \quad n \geq i, \quad n = 0, 1, 2, \cdots$

3. The Basic Ideas of HAM [1,15,18]

Let us have the following linear Des [17].

$N[z(t)] = 0$ (8)

Where N is a non-linear operator, t represents the independent variable, and z is an undefined function, by driving the classic homotopy technique, we get the zero orders deformation equation, which is defined below [18].

$(1 - q)\ \mathcal{L}\ [\beta(t, q) - z_0(t)] = q\ h\ H(t)\ N[\beta(t, q)]$ (9)

Where $q \in [0,1]$ represents the embedding parameter [19], which is called the homotopic parameter, $\mathcal{L}$ represents the auxiliary linear limit that fulfills the following property $\mathcal{L}(\mathrm{z}) = 0$, $\beta(t, q)$ also refers to the initial estimation of the exact solution, and h is called the convergence control parameter where $h \neq 0$, and $H(t)$ is an auxiliary function where $H(t) \neq 0$, when have $q = 0$ get

$\beta(t, 0) = z_0(t)$ (10)

Which represents the exact solution, and if had $q = 0$ then get

$\beta(t, 0) = z(t)$ (11)

Which represents the real solution to Eq. 8, thus as the parameter of homotopy q increases how much zero to one, the solution changes continuously from the initial guess $z_0(t)$ to the exact solution $z(t)$. This continuous change in solution is called the deformation in homotopy, as it is using the Taylor series for the parameter q.

$$z_1(t) = \beta(t,q) = z_0(t) + \sum_{j=1}^{+\infty} z_0(t) q^j \quad (12)$$

Whereas the

$$z_j(t) = \frac{1}{j!} \frac{\partial^j \beta(t,q)}{\partial q^j} \quad (13)$$

If $\mathcal{L}, z_0(t)$, $H(t)$ was correctly selected then the Taylor series would look like this

$$z_1(t) = \beta(t,q) = z_0(t) + \sum_{j=1}^{+\infty} z_0(t) \quad (14)$$

By deriving the zero-order deformation equation j times for the parameter q, then substituting for $q = 0$ and dividing the equation by $j!$ get the deformation equation of order j which is as follows:

$$\mathcal{L}\left[z_j(t) - \chi_j\, z_{j-1}(t)\right] = h\, H(t)\, R_{j-1}\left(\vec{z_{j-1}}(t)\right), \qquad z_j(0) = 0 \quad (15)$$

Where the vector is known as

$$\vec{z_j}(t) = \left\{z_0(t), \quad z_1(t), \quad z_2(t), \ldots, \quad z_j(t)\right\} \quad (16)$$

From Eq. 15 get

$$R_{j-1}\left(\vec{z_{j-1}}(t)\right) = \frac{1}{(j-1)!} \frac{\partial^{j-1} N[\beta(t,q)]}{\partial q^{j-1}}\Big|_{q=0} \quad (17)$$

$$\chi_j = \begin{cases} 0, & j \geq 1 \\ 1, & j < 1 \end{cases} \quad (18)$$

4. The Proposed Method SCA-HAM

The proposed method is based on calculating the optimal value of the HAM parameter (h) to figure out linear and non-linear ODEs by combining the HAM method with the SCA method, where the initial calculation is with a formula HAM.

$$z_j(t) = \chi_{j-1}\, z_{j-1}(t) + h\, L^{-1} R_j\left(\vec{z_{j-1}}(t)\right) \quad (19)$$

Using SCA will optimize the parameter h value in the HAM method to get the best solution.

5. Some Applications of SCA-HAM

Will solve some examples of ordinary linear and nonlinear DEs using HAM and improve the results using SCA.

5.1 Example [16]

$y'''' + 5y'' + 4y = 0$

And the exact solution

$z(t) = \frac{4}{3}\cos(t) + \frac{1}{3}\sin(t) - \frac{1}{3}\cos(2t) - \frac{1}{6}\sin(2t)$

And pick out the initial estimation

$z_0(t) = 1 + \frac{1}{6}t^3$

Then the linear operator (which represents the general solution)

$L[\beta(t;q)] = \frac{\partial^4 \beta(t;q)}{\partial t^4}$

Then have $L[c_1 + c_2 s + c_3 s^2 + c_4 s^3]$

The linear operator will look like this

$N[\beta(t;q)] = \frac{\partial^4 \beta(t;q)}{t^4} + 5\,\frac{\partial^2 \beta(t;q)}{t^2} + 4\,\beta(t;q) = 0$

And the initial condition

$z(0) = 1, z'(0) = 0$, $z''(0) = 0$, and $z(0) = 1$

Where

$R_j\left(\vec{z_{j-1}}\right) = z''''_{j-1} + 5z''_{j-1} + 4z_{j-1}$

Will work on finding the terms of the series using the following HAM law

$$z_j(t) = \chi_{j-1}\, z_{j-1} + h\, L^{-1} R_j\left(\vec{z_{j-1}}\right)$$

$$z_1(t) = \frac{1}{6}ht^4 + \frac{1}{24}ht^5 + \frac{1}{1260}ht^7$$

$$z_2(t) = \frac{1}{6}ht^4 + \frac{1}{6}h^2t^4 + \frac{1}{24}ht^5 + \frac{1}{36}h^2t^6 + \frac{1}{1260}ht^7 + \frac{29}{5040}h^2t^7 + \frac{1}{2520}h^2t^8 + \frac{1}{9072}h^2t^9 + \frac{1}{2494800}ht^{11}$$

$$z_3(t) = \frac{1}{20432412000}h^3t^{15} + \frac{1}{25945920}h^3t^{13} + \frac{1}{7484400}h^3t^{12} + \frac{1}{1247400}h^2t^{11} + \frac{83}{9979200}h^3t^{11} + \frac{1}{22680}h^3t^{10} + \frac{41}{72576}h^3t^9 + \frac{1}{4536}h^2t^9 + \frac{1}{1260}h^2t^8 \frac{11}{3360}h^3t^8 + \frac{29}{2520}h^2t^7 + \frac{3}{280}h^3t^7 + \frac{1}{1260}ht^7 + \frac{1}{18}h^2t^6 + \frac{1}{18}h^3t^6 + \frac{1}{12}h^2t^5 + \frac{1}{24}ht^5 + \frac{1}{24}h^3t^5 + \frac{1}{3}h^2t^4 + \frac{1}{6}h^3t^4$$

$$z_4(t) = \frac{1}{475176173472000}h^4t^{19} + \frac{1}{277880803200}h^4t^{17} + \frac{1}{81729648000}h^4t^{16} + \frac{1}{6810804000}h^3t^{15} + \frac{1}{504504000}h^4t^{15} + \frac{1}{90810720}h^4t^{14} + \frac{1}{8648640}h^3t^{13} + \frac{17}{38918880}h^4t^{13} + \frac{1}{2492800}h^3t^{12} \frac{29}{9979200}h^4t^{12} + \frac{83}{3326400}h^3t^{11} + \frac{143}{3628800}h^4t^{11} + \frac{1}{831600}h^2t^{11} + \frac{1}{7560}h^3t^{10} + \frac{7}{25920}h^4t^{10} + \frac{41}{24192}h^3t^9 + \frac{1}{3024}h^2t^9 + \frac{11}{8064}h^4t^9 + \frac{29}{3360}h^4t^8 + \frac{11}{1120}h^3t^8 + \frac{1}{840}h^2t^8 + \frac{9}{280}h^3t^7 + \frac{29}{1680}h^2t^7 + \frac{1}{3260}ht^7 + \frac{79}{5040}h^4t^7 + 6h^3t^6 + \frac{1}{12}h^2t^6 + \frac{1}{12}h^4t^6 + \frac{1}{8}h^2t^5 + \frac{1}{24}h^4t^5 + \frac{1}{24}ht^5 + \frac{1}{8}h^3t^5 + \frac{1}{2}h^2t^4 + \frac{1}{2}h^3t^4 + \frac{1}{6}ht^4 + \frac{1}{6}h^3t^4$$

⋮

So, substitute in the value of $h = -1$ get

$$z_1(t) = -\frac{1}{6}t^4 - \frac{1}{24}t^5 - \frac{1}{1260}t^7$$

$$z_2(s) = \frac{1}{36}t^6 + \frac{1}{1008}t^7 + \frac{1}{2520}t^8 + \frac{1}{9072}t^9 + \frac{1}{7484400}t^{11}$$

$$z_3(t) = -\frac{1}{2043241200}t^{15} - \frac{1}{25945920}t^{13} - \frac{1}{7484400}t^{12} - \frac{1}{133056}t^{11} - \frac{1}{22680}t^{10} - \frac{25}{72576}t^9 - \frac{5}{2016}t^8$$

$$z_4(t) = \frac{1}{745176173472000}t^{19} + \frac{1}{277880803200}t^{17} + \frac{1}{81729648000}t^{16} + \frac{1}{544864320}t^{15} + \frac{1}{90810720}t^{14} + \frac{5}{15567552}t^{13} + \frac{1}{399168}t^{12} + \frac{25}{1596672}t^{11} + \frac{1}{36288}t^{10}$$

⋮

Hence, the solution of the above series is shown in the following form

$$z(t) = z_0(t) + z_1(t) + z_2(t) + z_3(t) + z_4(t) + \cdots$$

$$z(t) \cong 1 + \frac{1}{6}t^3 - \frac{1}{6}t^4 - \frac{1}{24}t^5 - \frac{1}{1260}t^7 + \frac{1}{36}t^6 + \frac{1}{1008}t^7 + \frac{1}{2520}t^8 + \frac{1}{9072}t^9 + \cdots$$

Now and after using the SCA method to improve the parameter h, got better results by substituting for the value of $h^{new} = -0.9776$, The series solution of HAM-SCA can be written as a form

$$z^{new}(t) \cong {z_0}^{new}(t) + {z_1}^{new}(t) + {z_2}^{new}(t) + {z_3}^{new}(t) + {z_4}^{new}(t) + \cdots$$

$$\begin{aligned} z^{new}(t) \cong\ & -0.4572607681\ 10^{-5}t^{15} - 0.3600928549\ 10^{-7}t^{13} - 0.1248321897\ 10^{-6}t^{12} \\ & - 0.6621571294\ 10^{-5}t^{11} - 0.00004119462260\, t^{10} - 0.0002117671603\, t^9 \\ & - 0.001920960538\, t^8 + 0.004159320415\, t^7 + 0.02773658885\, t^6 \\ & - 0.04166619835\, t^5 - 0.1666647933\, t^4 + 0.1666667t^3 + 1 + \cdots \end{aligned}$$

The comparison of results between HAM and HAM-SCA is shown in Table 1 and Figure 2.

Table 1: Comparison of MAE and MSE for HAM and HAM-SCA for Example 1.

Error Criteria	HAM	HAM-SCA
MSE	$2.334360\ E-9$	$9.033345\ E-12$
MAE	$2.035680\ E-5$	$1.555098\ E-6$

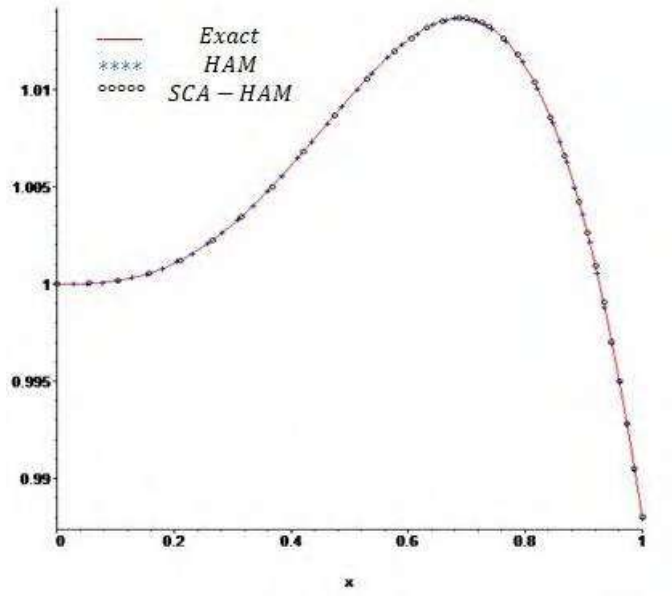

Figure 2: Illustrates the matching process between HAM, HAM-SCA, and exact solution.

5.2 Example [16]

$y'' + y'^2 = 0$

And the exact solution

$z(t) = 1 + \ln(1 + 2t)$

And pick out the initial estimation

$z_0(t) = 1 + 2s$

And the initial condition

$z(0) = 1, \quad z(0) = 2$

The linear operator (which represents the general solution)

$L[\beta(t;q)] = \frac{\partial^2 \beta(t;q)}{\partial t^2}$

Then have $L[c_1 + c_2 s] = 0$

Using Adomian polynomials expand the nonlinear y'^2 a term which will be in the following form

$\sum_{i=0}^{j-1} z_i'(t)\ z'_{j-1-i}(t)$

The linear operator will look like this

$N[\beta(t;q)] = \frac{\partial^2 \beta(t;q)}{s^2} + \frac{\partial \beta^2(t;q)}{s^2}$

And

$R_j(\vec{z_{j-1}}) = z''''_{j-1}(t) + \sum_{i=0}^{j-1} z_i'(t)\ z'_{j-1-i}(t)$

Will work on finding the terms of the series using the following (HAM) law

$z_j(t) = \chi_{j-1}\, z_{j-1} + h\, L^{-1} R_j(\vec{z_{j-1}})$

$z_1(t) = 2ht^2$

$z_2(t) = 2ht^2 + 2h^2t^2 + \frac{8}{3}h^2t^3$

$z_3(t) = 4h^3t^4 + \frac{16}{3}h^2t^3 + \frac{16}{3}h^3t^3 + 2ht^2 + 4h^2t^2 + 2h^3t^2$

$z_4(t) = \frac{32}{5}h^4t^5 + 12h^3t^4 + 12h^4t^4 + 8h^2t^3 + 8h^4t^3 + 16h^3t^3 + 2ht^2 + 6h^2t^2 + 2h^4t^2$

$\vdots$

So, substitute in the value of $h = -1$ get

$z_1(t) = -2t^2$

$z_2(t) = \frac{8}{3}t^3$
$z_3(t) = -4t^4$
$z_4(t) = \frac{32}{5}t^5$
⋮
Then the series solution of HAM with $h = -1$ can be written as a form
$z(t) = z_0(t) + z_1(t) + z_2(t) + z_3(t) + z_4(t) + \cdots$
$z(t) \cong 1 + 2t - 2t^2 + \frac{8}{3}t^3 - 4t^4 + \frac{32}{5}t^5 + \cdots$

Now and after using the SCA method to improve the parameter h, got better results by substituting for the value of $h^{new} = -0.4888$, The series solution of HAM-SCA can be written as a form
$z^{new}(t) \cong {z_0}^{new}(t) + {z_1}^{new}(t) + {z_2}^{new}(t) + {z_3}^{new}(t) + {z_4}^{new}(t) + \cdots$
$z^{new}(t) \cong 0.365346341626839\, t^5 - 1.18356369060168\, t^4 + 1.78803919216422\, t^3 - 1.86341802881761\, t^2 + 2s + 1 + \cdots$
The comparison of results between HAM and HAM-SCA is shown in Table 2 and Figure 3

Table 2: Comparison of MAE and MSE for HAM and HAM-SCA for Example 2.

Error Criteria	HAM	HAM-SCA
MSE	2.056038	$9.204092\ E-6$
MAE	0.758987	$2.33752\ E-3$

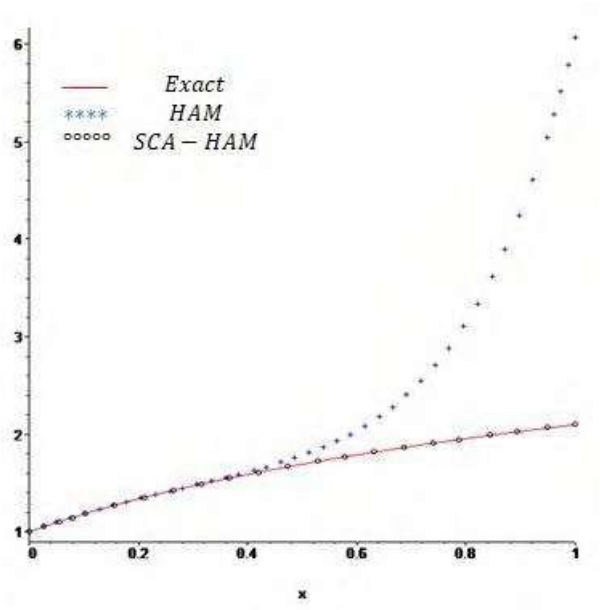

Figure 3: Illustrates the matching process between HAM, HAM-SCA, and exact solution.

5.3 Example [16]
$y'''' + yy'' - y'^2 = 0$
And the exact solution
$z(t) = e^t - 1$
And pick out the initial estimation
$z_0(t) = t + \frac{1}{2}t^2 + \frac{1}{6}t^3$
And the initial condition
$z(0) = 0 \quad , \quad z'(0) = 1 \quad , \quad z''(0) = 1 \quad , \quad z'''(0) = 1$

the linear operator (Which represents the general solution)

$L[\beta(t;q)] = \frac{\partial^4 \beta(t;q)}{\beta s^4}$

Then have $L[c_1 + c_2 s + c_3 s^2 + c_4 s^3]$

Using Adomian polynomials expand the nonlinear $yy'' - y'^2$ a term which will be in the following form

$\sum_{i=0}^{j-1} z_i(t)\, z'_{j-1-i}(t) - \sum_{i=0}^{j-1} z'_i(t)\, z'_{j-1-i}(t)$

The linear operator will look like this

$N[\beta(t;q)] = \frac{\partial^4 \beta(t;q)}{t^4} + \frac{\partial \beta^2(t;q)}{t^2}\, \beta(t;q) - \frac{\partial \beta^2(t;q)}{t^2}$

And

$R_j(\vec{z_{j-1}}) = z'''' _{j-1}(t) + \sum_{i=0}^{j-1} z_i(t)\, z'_{j-1-i}(t) - \sum_{i=0}^{j-1} z'_i(t)\, z'_{j-1-i}(t)$

Will work on finding the terms of the series using the following (HAM) law

$z_j(t) = \chi_{j-1}\, z_{j-1} + h\, L^{-1} R_j(\vec{z_{j-1}})$

$z_1(t) = -\frac{1}{24}ht^4 - \frac{1}{120}ht^5 - \frac{1}{270}ht^6 - \frac{1}{2520}ht^7 - \frac{1}{20160}ht^8$

$z_2(t) = h\left(-\frac{1}{24}ht^4 - \frac{1}{120}ht^5 - \frac{1}{270}ht^6 - \frac{1}{2520}ht^7 - \frac{1}{20160}ht^8\right) + h\left(\frac{1}{148262400}ht^{13} - \frac{1}{11404800}ht^{12} - \frac{1}{19958400}ht^{11} - \frac{1}{453600}ht^{10} + \frac{1}{362880}ht^9 - \frac{1}{13440}ht^8 - \frac{1}{1680}ht^7 - \frac{1}{720}ht^6 - \frac{1}{120}ht^5 - \frac{1}{24}ht^4\right)$

$z_3(s) = -\frac{1}{20160}ht^8 - \frac{1}{2520}ht^7 - \frac{1}{720}ht^6 - \frac{1}{120}ht^5 - \frac{1}{24}ht^4 - \frac{1}{74131200}h^2t^{13} - \frac{1}{5702400}h^2t^{12} - \frac{13}{9979200}h^2t^{11} - \frac{1}{226800}h^2t^{10} - \frac{1}{181440}h^2t^9 - \frac{1}{6720}h^2t^8 - \frac{1}{840}h^2t^7 - \frac{1}{360}h^2t^6 - \frac{1}{60}h^2t^5 - \frac{1}{12}h^2t^4 - \frac{53}{23691859200}h^3t^{15} - \frac{11}{1981324800}h^3t^{14} - \frac{7}{222393600}h^3t^{13} - \frac{127}{479001600}h^3t^{12} - \frac{79}{39916800}h^3t^{11} - \frac{29}{106748928000}h^3t^{16} - \frac{829}{29640619008000}h^3t^{17} - \frac{829}{533531142144000}h^3t^{18} - \frac{1}{145152}h^3t^{10} - \frac{1}{181440}h^3t^9 - \frac{1}{10080}h^3t^8 - \frac{1}{1260}h^3t^7 - \frac{1}{720}h^3t^6 - \frac{1}{120}h^3t^5 - \frac{1}{24}h^3t^4$

⋮

So, substitute in the value of $h = -1$ get

$z_1(t) = \frac{1}{24}t^4 + \frac{1}{120}t^5 + \frac{1}{270}t^6 + \frac{1}{2520}t^7 + \frac{1}{20160}t^8$

$z_2(t) = \frac{1}{148262400}t^{13} + \frac{1}{11404800}t^{12} + \frac{1}{19958400}t^{11} + \frac{1}{453600}t^{10} + \frac{1}{362880}t^9 + \frac{1}{40320}t^8 + \frac{1}{5040}t^7$

$z_3(t) = \frac{829}{533531142144000}t^{18} + \frac{829}{296406190080000}t^{17} + \frac{29}{106748928000}t^{16} + \frac{53}{32691859200}t^{15} + \frac{11}{1981324800}t^{14} + \frac{1}{55598400}t^{13} + \frac{43}{479001600}t^{12} + \frac{1}{1478400}t^{11} + \frac{1}{403200}t^{10}$

$z_4(s) = -\frac{101}{416860435031040000}t^{23} - \frac{101}{18124366740480000}t^{22} - \frac{14009}{202741834014720000}t^{21} - \frac{36121}{67580611338240000}t^{20} - \frac{9487}{3801409387776000}t^{19} - \frac{13547}{1600593426432000}t^{18} - \frac{3023}{88921857024000}t^{17} - \frac{677}{2615348736000}t^{16} - \frac{163}{100590336000}t^{15} - \frac{23}{4151347200}t^{14} - \frac{23}{2075673600}t^{13}$

⋮

Then the series solution can be written as a form

$z(t) = z_0(t) + z_1(t) + z_2(t) + z_3(t) + z_4(t) + \cdots$

$z(t) \cong \frac{1}{24}t^4 + \frac{1}{120}t^5 + \frac{1}{270}t^6 + \frac{1}{2520}t^7 + \frac{1}{20160}t^8 + \cdots$

When using SCA to improve the parameter h, the best result was $h = -1$, which is the same in HAM.

The comparison of results between HAM and HAM-SCA is shown in 3able 1 and Figure 4.

Table 3: Comparison of MAE and MSE for HAM and HAM-SCA for Example 3

Error Criteria	HAM	HAM-SCA
MSE	2.056038	$9.204092\ E-6$
MAE	0.758987	$2.33752\ E-3$

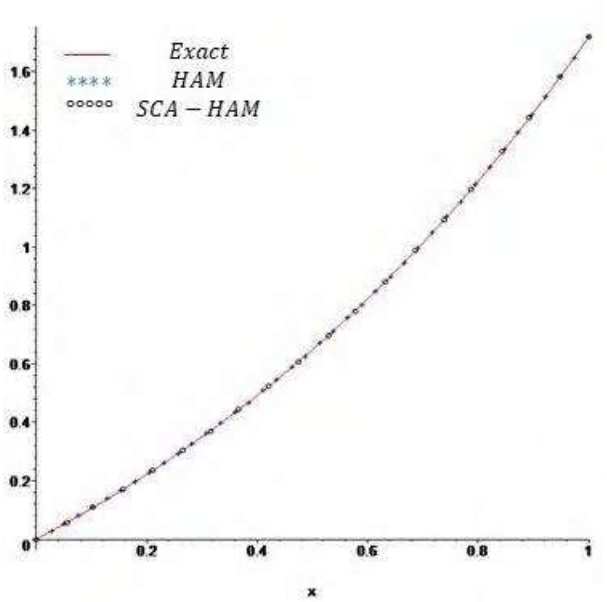

Figure 4: Illustrates the matching process between HAM, HAM-SCA, and exact solution.

Conclusion

In this work, a hybrid method SCA-HAM is implemented between the HAM and the SCA. A series of approximate solutions in the HAM has been applied as a fitness function in the SCA to find the optimal h parameter. The outcome of the SCA-HAM method (which contains the optimal parameter (h)) was compared with the HAM through three examples illustrated in Tables (1-3) and Figure (2-4), where the SCA-HAM shows a clear superiority over HAM in discovering approximate solutions through calculating the MSE and MAE.

Abstract. In this manuscript, the elastic electron scattering form factors and the nucleon momentum distributions (NMD) for stable ^{15}N and neutron halo ^{16}N at the ground state were reported. This was accomplished by utilizing the well-known Coherent Density Fluctuation Model (CDFM) via the employment of fluctuation function ($|F(q)|^2$) which is coupled with the density distributions nuclei. The long-tail performance in the NMD at high momentum region was further determined via experimental and theoretical fluctuation functions. The evaluated elastic electron scattering form factors were evaluated on the bases of the density distributions as well as the root mean square (RMS) radii for each measured nucleon. The proposed study provides a robust correlation between the theoretical formation factors and the practical results of ^{15}N and ^{16}N nuclei.

Keywords: CDFM, ^{15}N and ^{16}N, density distributions, RMS radii

1. Introduction

The elastic electron scattering, the density distributions, as well as RMS radii are considered as the most fundamental quantities, which provide insights about the inner structure of both neutron and proton. These together are known as nucleons [1-4]. Recently, several approaches have been proposed for the sole purpose to determine the aforementioned quantities. A typical example of this is the discovery of the halo phenomenon in the stable and exotic nuclei [4, 5]. In the case of stable nuclei, the elastic electron scattering is to be considered a dominant quantity for investigating the nuclear structure. This can be mainly attributed to the interaction of electron with nucleus which is attained via electromagnetic interaction [3]. Generally, a halo nucleus, since its discovery in 1985, possesses large neutron and proton excess whereby the bounds of few outer nucleons are considered weak [6]. The halo nature of a nucleus is principally caused by a specific effect which in turn can be attributed to a continuum close bound state. The essential requirements for the occurrence of a halo are short-range interaction, relatively low angular momentum and low binding energy [7]. A neutron halo is not limited to the unstable nuclei, however, it is usually observed in exotic nuclei on a large-scale as compared to the stable nuclei. The neutron halo could also be perceived off the β-stability line [8]. The previous studies reported that several ground state nuclei possess a halo structure, which is in a close position to the drip-line. These halos can be one-neutron halo (11Be and 19C), two-neutron halo (14Be, 11Li, and 6He), three-neutron halo (26F) and four-neutron-halo (8He) [9-15]. Moreover, the valence neutron can be channeled into the space near the nuclear core so that the neutron is extended with some distance. This distance is estimated to be of higher value as compared to the typical nuclear radius. Therefore, the angular momentum may have some influence on the halo formation which in turn leads to a probability of the s-state to be outside the core's potential range [6, 16, 17]. However, the pandd-states possess much lower probability to form a halo structure due to the relatively large centrifugal barrier[18].

As such, a number theoretical attempts were proposed to investigate the elastic electron scattering form factors as well as the NMD. Karataglidis and Amos [19] demonstrated the transverse and longitudinal form factors from isotopes such as He, Li, and 8Bi. Roca-Maza et al. reported a systematic investigation regarding the elastic electron scattering of both unstable 36Ca and stable 40Ca nuclei using the phase-shift analysis model [20]. Another research group supervised by Chu, Y. et al, also considered the elastic electron scattering of S and O isotopic chains in which they stated that the phase-shift analysis model is capable of reproducing the data obtained experimentally for both heavy and light nuclei [21]. Lately, Hamodi et al. revealed the calculation of the NMD and elastic electron scattering for odd and even p-shell nuclei using CDFM [22]. In this theory, which is an original effort of Antonov et al.[23], the NMD as well as nucleon density distributions (NDD) can only be linked and consequently expressed of the available weight function, $|f(x)|^2$, obtained experimentally. The same research group examined the NMD of some stable and unstable nuclei (4He, 16O, 12C, 40Ca, 39K, and 48Ca) expressed via weight function by means of NDD using the two-parameter fermi (2pF) model [24, 25]. The elastic electron scattering and NMD were observed for 1p-shell, sd-shell, as well as fp-shell nuclei through the CDFM framework [2, 26, 27]. Another study conducted by Ridha et al. reported the investigation of the NDD and elastic charge form factors of 11Be, 19C, 11Li, 8B, 17Ne, 4He, 12C and 16O nuclei using Woods Saxon single-particle radial wave function. The outcomes were compared with harmonic-oscillator potential [28-31]. They found that the utilized Wood Saxon single-particle wave function is in a good agreement with stable and exotic nuclei experimental data. In the same framework, the NDD was also examined alongside the elastic electron scattering for 48Ca and 40Ca nuclei[32]. In this attempt, the study is conducted to explore the elastic electron scattering form factors, density distributions, and RMS radius of stable 15Nandneutron halo 16N nuclei via neutron halo outside the core utilizing two approaches namely CDFM and 2pF.

2.Theory

A single body operator's NDD can be expressed as demonstrated in Equation (1).

$$\rho(r) = \frac{1}{4\pi}\sum_{nl} \xi_{nl}\, 4(2l+1)|R_{nl}|^2 \quad (1)$$

whereby the state $n\ell$ nucleon occupation probability is represented byξ_{nl}, (closed-shell nuclei: $\xi_{nl} = 0\ or\ 1$; and open-shell nuclei:$0 < \xi_{nl<1}$), while R_{nl} is the single-particle harmonic oscillator wave functionradial part.

The NDD of 15N and 16N nuclei represented at the 2s1d-shell end is derived based on a particular hypothesis by which an occupied shell core is existed (1s as well as 1p) and the nucleon occupation numbers in 2s and 1d shells are equal to (4-α), and (A-20+α1), respectively. Meanwhile, it is in a simple shell model (4) and (A-20). Using this assumption with Equation (1), the form of the analytical NDD is given as:

$$\rho(r) = \frac{exp(-R^2/b^2)}{\pi^{3/2}b^3}\left\{10 - \frac{3}{2}\alpha_1 + 2\alpha_1(\frac{r}{b})^2 + (\frac{4A}{15} - \frac{8}{3} - \frac{2\alpha_1}{5})(\frac{r}{b})^4\right\} \quad (2)$$

Herein, the mass number is represented by the letter A, while b is the size parameter, α1 describes the occupation numbers deviation of the nucleon from the shell model where α1=0 and α2 are presumed as an uncontrolled parameter which must be adjusted to have a covenant alongside the regarded NDD experimental measurements. Herein, the normalization condition of ρ(r) can be expressed as [31].

$$N = 4\pi\int_0^\infty \rho(r)r^2dr \quad (3)$$

The RMS radii of the nuclei is expressed as follow [31]:

$$< r^2 >^{1/2} = (\frac{4\pi}{N}\int_0^\infty \rho(r)r^4dr)^{1/2} \quad (4)$$

At central density$\rho(r) = 0$, the NDD at the nucleus center from Equation (2) is given as:

$$\rho(0) = \frac{1}{\pi^{3/2}b^3}\left(10 - \frac{3}{2}\alpha_1\right) \quad (5)$$

so α_1 becomes:

$$\alpha_1 = \frac{2}{3}\left(10 - \rho(0)\pi^{3/2}b^3\right) \quad (6)$$

By substituting Equation (2) into Equation (4) with some simplification:

$$\langle r^2\rangle = \frac{b^2}{A}\left(\frac{9A-120}{2} + \alpha_1\right) \quad (7)$$

herein, the central density $\rho(0)$ and $\langle r^2\rangle$ values are obtained using the experimental values whereas the parameter b is nominated to duplicate the RMS radii of a nucleus obtained experimentally.

The NMD, n(k), of the nuclei is considered via two different models. One of which is calculated using the shell model through single-particle harmonic oscillator wave functions in momentum demonstration, and it is assumed using Equation (8) [31]:

$$n(k) = \frac{b^3}{\pi^{3/2}} \exp(-b^2k^2)\left(10 + 8(bk)^4 + \frac{8(A-40)}{105}(bk)^6\right) \quad (8)$$

where the symbol k- represents the particle momentum.

In the meanwhile, the second model (NMD) is considered using the CDFM, whereby Equation (9) represents the mixed density [33, 34].

$$\rho(r,r') = \int_0^\infty |f(x)|^2 \rho_x(r,r')dr \quad (9)$$

herein a density matrix for A nucleon distributed equivalently at radius x of the sphere can be given by [11]:

$$\rho_x(r,r') = 3\rho_0(x)\frac{j_1\left(k_{F(x)}|r-r'|\right)}{k_F|r-r'|}\theta\left(x - \frac{1}{2}|r-r'|\right) \quad (10)$$

where the density is$\rho_0(x) = 3A/4\pi x^3$;kF is the Fermi momentum, given as [35]:

$$k_F(x) = \left(\frac{3\pi^2}{2}\rho_0(x)\right)^{1/3} = \left(\frac{9\pi A}{8}\right)^{1/3}\frac{1}{x} = \frac{\alpha}{x} \quad (11)$$

and θ is the step function ($\theta = 0\ or\ 1$). Equation (9) corresponds to an equation in a CDFM because the nuclear material fluctuates and tries to maintain the spherical shape of the nucleus and its symmetry.

The density of the single-particle based on the diagonal element of Equation (9) can be expressed as presented in Equation (12) [34]:

$$\rho(r) = \rho_x(r,r'=r)\int_0^\infty |f(x)|^2\rho_x(r)dx) \quad (12)$$

where $\rho_x(r) = \rho_0(r)\theta\ (x-r)$ and the weight function can be expressed as presented in Equation (13) [23, 34]:

$$|f(x)|^2 = \frac{-1}{\rho_0(x)}\frac{d\rho(r)}{dr} \quad (13)$$

The NDD is then calculated with respect to the normalization condition:$\int_0^\infty |f(x)|^2 = 1$.

According to Equation (12) the nucleon momentum distribution can be given as [33, 34]:

$$n(k) = \int_0^\infty |f(x)|^2 n_x(k)dx \quad (14)$$

where the Fermi -momentum distribution of all nucleons is given as,

$$n_x(k) = \frac{4}{3}\pi x^3\theta(k_F(x) - |k|) \quad (15)$$

and using weight function and Equations (13 and 14) the nucleon momentum in CDFM can be expressed as:

$$n_{CDFM}(k) = \left(\frac{4\pi}{3}\right)^2\frac{4}{A}\left[6\int_0^{\alpha/k}\rho(x)x^5dx - \left(\frac{\alpha}{k}\right)^6\rho\left(\frac{\alpha}{k}\right)\right] \quad (16)$$

With a normalized condition: $A = \int n_{CDFM}(k)\frac{d^3k}{(2\pi)^3}$.

For the target nucleus form factor F (q), the expression in coherent density fluctuation model can be given as [33, 34]:

$$F(q) = \frac{1}{A}\int |f(x)|^2 F(q,x)dx \quad (17)$$

Where the uniform charge density distribution is represented as F (q, x) that reflects the scattering event in CDFM with amplitude is a superposition of all charge distribution, which can be expressed as,

$$F(q,x) = \frac{3A}{(qx)^2}\left[\frac{\sin(qx)}{(qx)} - \cos(qx)\right] \quad (18)$$

Equation (18) must be multiplied by a correction of free nucleon finite-size form factor (same protons and neutrons) and center of mass form factor. This eliminates the false state appears from the indication of the mass center. These form corrections can be expressed as follow [31]:

$$F_{fs}(q) = \exp\left(\frac{-0.43q^2}{A}\right)\ and\ F_{cm}(q) = \exp\left(\frac{b^2q^2}{4A}\right) \quad (19)$$

The weight function ($|f(x)|^2$) is obtained using the estimatedNDDfrom2pF model by which the experimental elastic electron scattering was utilized as an input quantity. Consequently, the theoretical value of the mention elastic electron scattering was also used as a comparison point.

Wood-Saxon function for the density of 2pF is given by [27]

$$\rho_c(r) = \frac{\rho_0}{1+\exp(r-c/z)} \quad (20)$$

So, the weight function will be:

$$|f(x)|^2 = \frac{4\pi x^3 \rho_0}{3Az}(1 + \exp(x - c/z))\exp(x - c/z) \qquad (21)$$

If Equation (2) inserted into the equation of weight function (13), an analytical expression cab be acquired as,

$$|f(x)|^2_{2pF} = \frac{8\pi x^4 \rho(x)}{3Ab^2} - \frac{16x^4}{3A\pi^{1/2}b^5}\left\{\left[\alpha_1 + \frac{4A}{15} - \frac{8}{3} - \frac{2\alpha_1}{5}\right](\frac{x}{b})^2\right\} \qquad (22)$$

3. Results and discussion

Table 1: The parameters used in the determination of nuclear density.

Nucle i	c (fm)	z (fm)	b (fm)	$\rho(0)$ (fm^{-3})	α_1
^{15}N	2.638	0.520	1.710	0.2698	1.6586
^{16}N	2.692	0.523	1.72	0.2673	1.7050

3.1 Root *mean square* radii

The proton, neutron (R_p and R_n) and the matter RMS radii of the core and halo are generally evaluated using the harmonic oscillator radial wave function potential or radial wave function of Wood-Saxon potential, respectively. The R_p and R_n matter RMS radii obtain educing Equation (4) are summarized in Table (2). As presented in Table (2), the R_p, R_n matter RMS radii exhibited small differences in^{15}N and ^{16}N nuclei. It is noteworthy mentioning that the only input in the utilized densities calculation is the matter radii(R_m).Table (2) tabulates the calculated charge RMS radius for both ^{15}N and ^{16}N nuclei with the corresponding available experimental values using previously published data [36]. The obtained results of ^{15}N are in an upright agreement with the reported data, while the evaluated values of ^{16}N RMS radius are relatively smaller.

Table 2: RMS radius values of proton and neutron compared with experimental data.

Nuclei	RMS radius(fm)		RMS present work	
	Present work	Experimental	Proton	Neutron
^{15}N	2.426	2.42∓0.10 [36]	2.4084	2.431
^{16}N	2.479	2.50∓0.10 [36]	3.743	3.85

3.2 Density distributions

The density distributions analysis of both ^{15}N and ^{16}N nuclei are presented in this section using 2pF model, as expressed in Equation (20). The main reason for these nuclei to be selected is the unavailability of experimental density distributions data[24]. In the current study, the density distributions is calculated based on two parameters one of which is nucleus radius (c), while another is the skin thickness (z). The NDD is based primarily on the (c) value, particularly when the value of (c)is greater than the nuclei RMS radius. Herein, the (c) value rises as the mass number increases, particularly when the nuclear core and halo skin thicknesses are considered constant. This can be clearly observed from Table (1) and (2).

The ^{15}N nucleus density distributions were presumed through the consideration of the nucleus as a core and consequently evaluating its density distribution; assuming to be of similar shape to the Wood-Saxon alongside the 0.65 fm as the diffuseness parameter. The signal-neutron wave function can be estimated through solving Schrodinger formula which in turn can be solved using Wood-Saxon and/or Coulomb potentials; this can be advantageous in attaining a precise separation energies of the neutron, which corresponds to 1p, 2s as well as 1d orbitals. The total density distributions were obtained by adding the so-called nucleus as a core and the wave function parts. Similarly, 16N analysis was conducted assuming that a single neutron and 15N core are composed.

The distribution of the cores was noticed to be practically indistinguishable. The 15N and 16N density distributions are very alike, yet the single-neutron of 15N ranges was found to be considerably high-spaced because of the relatively small separation energy of the neutron (0.108 MeV). It should be mentioned that the corresponding energy separation of the neutron value for 16N being 0.248 MeV. Figure 1 (a and b) illustrates the NDD for both 15N and 16N nuclei as a function of the distance (r) in fm. The solid curves in Figure 1 are calculated theoretically using Equation (2), while the dotted curves are the experimental NDD data of the 2pF. The two curves showed the same behavior in falling as r increases in the region of the single-neutron.

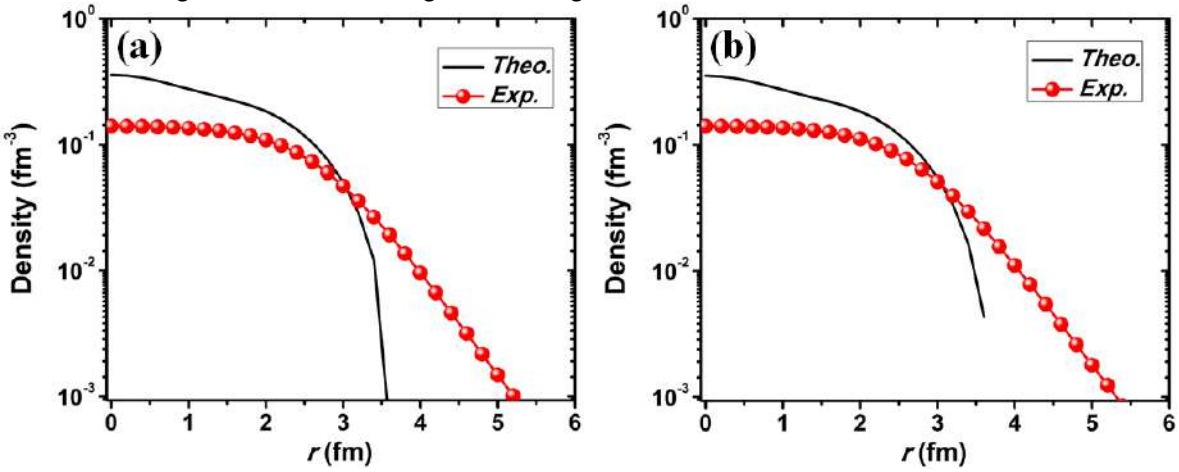

Figure 1: The evaluated nucleon density distributions for both ^{15}N (a) and ^{16}N (b) nuclei. The core ^{15}N is considered for ^{16}N, while the halo single-neutron is represented separately. The experimentally obtained nucleon density distributions are also presented using 2pF model.

3.3 Nucleon momentum distributions

To calculate the NMD, the CDFM model is used as expressed in Equation (16). In Figure 2 (a and b), the NMD is plotted as a function of the momentum $k(fm^{-1})$for ^{15}N and ^{16}N nuclei, respectively. The NMD dotted and solid curves are evaluated using theoretical and experimental weight function $|f(x)|^2$, respectively. It is worth mentioning that the general performance of the NMD at regions of high momentum ($k \geq 2$ fm^{-1}) for both ^{15}N and ^{16}N nuclei are similar; whereby the mentioned distributions possess the properties of a long-tail which are in a well agreement with other reported studies [27-30]. The long-tail in Figure (2), attained using CDFM, is correlated with that of high densities $\rho_x(r)$, Equation (12). This particular hypothesis concludes that ^{15}N and ^{16}N nuclei fluctuation function $|f(x)|^2$ is relatively minor, and these outcomes are in an upright agreement with other data obtained experimentally [25].

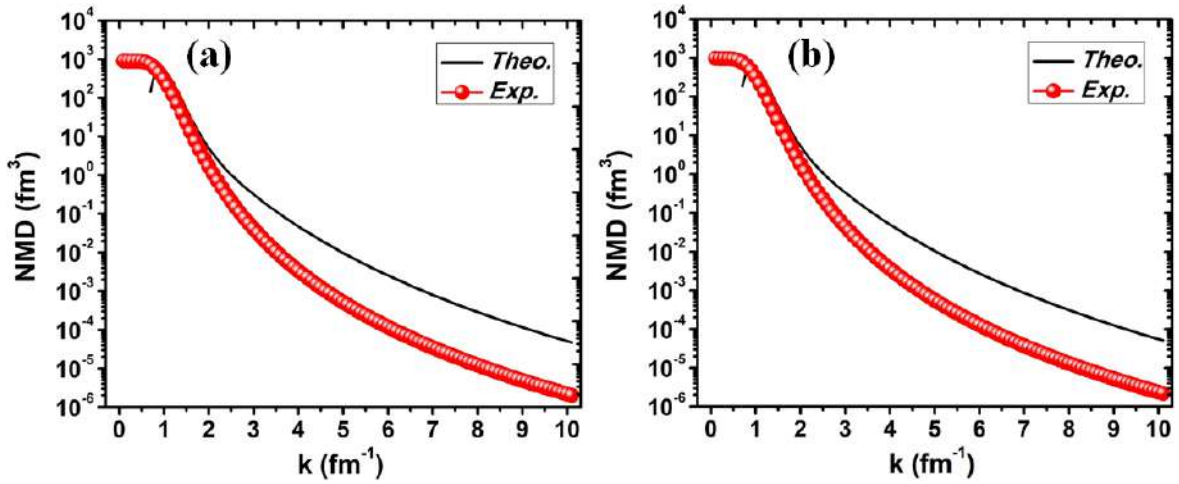

Figure 2: The NMD versus *k* for ^{15}N "(a) and ^{16}N (b) nuclei. The curve with red circles is the evaluated NMD which is expressed using CDFM, while the black solid curve is the evaluated NMD using Equation (8).

3.4 Elastic form factors

The nuclei electron scattering quantity provides good insights about the nucleus charge and size distributions. The presented results in Figure 3, calculated in the framework of CEDM according to Equation (18), are plotted as a function of momentum transfer q (fm^{-1}) for ^{15}N and ^{16}N nuclei. The solid as well as dotted curve in Figure 3 (a and b) are the evaluated results with the correction form included and excluded of the finite-size nucleon and mass center using Equation (19), respectively. Elastic form factors experimental data are plotted as solid circles for the considered nuclei. Figure 3 (a and b) elucidates the form factors obtained experimentally of ^{15}N and ^{16}N nuclei which are considered to be in good agreement with those obtained theoretically. The corrections of the form factor (red dotted curve) showed a slight reduction in comparison to the presented calculation prior to the corrections (solid black curve). The presented correction of the form factor is closer to the experimental values.

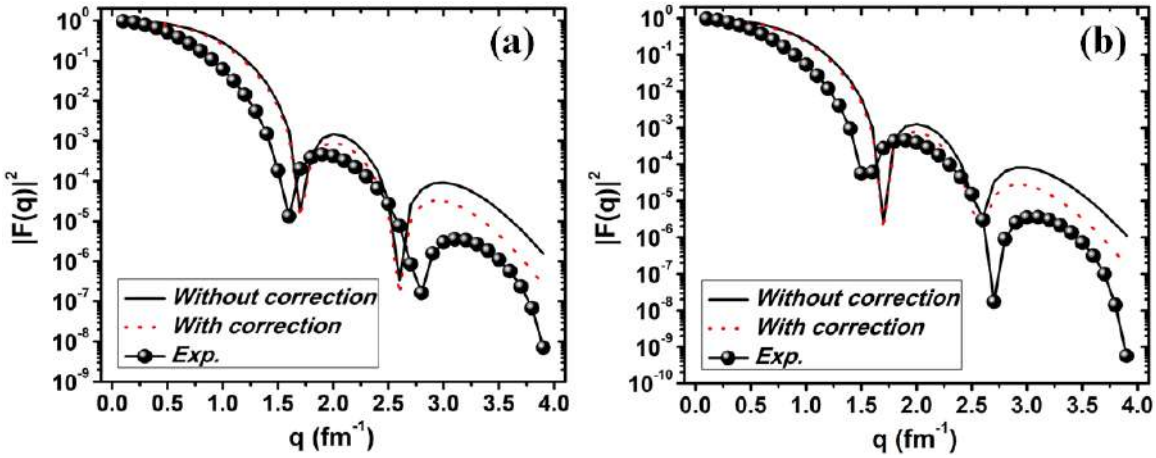

Figure 3: The charge form factors squared for elastic electron scattering for ^{15}N (a) and ^{16}N (b) nuclei as a function of the momentum transfer.

4.Conclusion

In the present study, the charge density distributions using 2pF model for ^{15}Nand ^{16}N were reported. Furthermore, using the obtained density distributions, the form factors were also evaluated which in turn suggested that the form factor depends on the density distributions and RMS radii. It was observed from the current investigation that the differences between neutron and proton RMS radii for each nuclei are small which agreed with experimental data. The ground state nucleon and matter densities of stable ^{15}N and exotic neutron halo nuclei ^{16}N were estimated using the CDFM. The long-tail feature performance at the high momentum region of the NMD was demonstrated utilizing both experimental and theoretical weight functions. The perceived nuclei electron scattering form factors in the current study are well-reproduced using the current evaluation throughout the momentum transfer value (q).

Risk Determination of Radionuclide Derived from Agriculture Fertilizers in Iraqi Markets by Gamma Spectrometry

Risk Determination of Radionuclide Derived from Agriculture Fertilizers in Iraqi Markets by Gamma Spectrometry

Akram Mohammed Ali

E-mail: dr.akram@uoanbar.edu.iq

Abstract. A fertilizer has increase production and becomes a necessary tool that uses in agriculture. Different amount of uranium and thorium are including in the fertilizers that mean natural nuclide will be concentrated in high values. In this work, seventeen samples of commonly used fertilizer in Iraqi markets were collected and determine the specific activities of radiation ^{238}U, ^{232}Th, and ^{40}K using a technique of gamma-ray spectroscopy NaI(Tl) detector. The concentration of these nuclides has average values (79.66±0.41Bq/kg, 30.52±0.31Bq/kg, and 181.27±2.91 Bq/kg) comparing with worldwide limitation (35Bq/kg, 35Bq/kg, and 350 Bq/kg), respectively. So the concentration of ^{238}U nuclei greater than its global limit. The radiological hazards of all samples as radium equivalent activity (Raeq), external (H_{ex}) and internal (H_{in}), alpha and gamma indices, and annual effective dose, due to the presence of these radionuclides, were calculated to assess it hazards and by the statistical study that using SPSS program one can mark the relations between all hazards indices.

Keywords: Radionuclide, Fertilizer, NaI(TI) detector, hazard indices, Cluster statistic.

1. Introduction.

Residents were exposed to naturally occurring radionuclides which are found in various sources, among them fertilizers that are used in agriculture. The use of fertilizers in agriculture gives good information to hand out the specific activities of ^{238}U, ^{232}Th, and ^{40}K in the environment. All corps need to grow up quickly, easily, and healthy. With some steroids as fertilizers in reasonably priced application depending on the soil type and its fertility where some crops do not require fertilizer as legumes, one can get what is desirable. Fertilizers are solid and liquid, the solid fertilizer is mostly inorganic as urea, di-ammonium, phosphate, and potassium chloride. The solid shape either granulate or powder that composed mainly of nitrogen (N), potassium (K), and phosphorus (P). However, the extensive use of fertilizers can increase environmental effects. The increasing consumption of it can affect soil, surface, and ground waters because of the dispersion of element using. Many studies have shown that agricultural fertilizers contain varying amounts of natural radioactive material [1-3]. The radioactive elements that imply fertilizers differ in amount depending on their concentration such as Uranium-238. As the concentration increase of the natural radionuclides in fertilizers, the risk of human health from this nuclide increases.

The use of natural fertilizers in wide-ranging Iraqi markets may lead to the distribution of radionuclide elements in the agricultural areas that will become a source of radioactivity decay. This phenomenon may lead to potential radiation hazards due to external exposure to gamma and alpha particles (external and internal) radiation by workers in factories where fertilizer produced, formers, or

residents of forms. In several markets, there are several types of fertilizers used in agriculture as di-ammonium phosphate and nitrogen urea, and so on. Their concentrations must be measured in fertilizer to specify the safe employment of fertilizers. The concentration of radium and uranium contentment in the soil is increasing the radiation dose and absorbed dose in the human body which leads to unwanted health prohibitions.

This evaluation aims to build a level for concentrations of radioactive nuclei in used samples and find a correlation between concentrations and radioactive parameters comparing with word limits. Besides, existing a relationship between activity concentration and hazard index using statistical methods(cluster, Pearsons, and descriptive).

2. Material and Methods:

*Sample collection***:** Seventeen samples of the most available types of fertilizers in local markets in Iraq were collected and prepared to measure the natural activity. The type samples are listed in Table 1 where each plastic bag is labeled by its name.

Table 1. The details of the fertilizer sample under test.

Samples name	Sample code	Type	Origin
Fertilizer 1	F1	O-DAP Micronutrients	Iraqi (Kufa)
Fertilizer 2	F2	K-Humate (N-13, P-22, K-18)	Iraqi (Kufa)
Fertilizer 3	F3	Nitrogen -Urea	Iraqi (Basra)
Fertilizer 4	F4	Nitrogen -Urea	Ukrainian
Fertilizer 5	F5	Nitrogen -Urea	Iranian
Fertilizer 6	F6	Phosphate daimonian	Jordanian
Fertilizer 7	F7	Phosphate daimonian	Jordanian
Fertilizer 8	F8	N-P component	Iraqi (Basra)
Fertilizer 9	F9	Compost	Iraqi (municipal)
Fertilizer 10	F10	Nitrogen -Urea (EFC)	Egyptian
Fertilizer 11	F11	Nitrogen -Urea	Egyptian
Fertilizer 12	F12	Potassium Nitrate (NP)	Jordanian
Fertilizer 13	F13	Potassium Nitrate (NP)	Chinese
Fertilizer 14	F14	Potassium Nitrate (NP)	Saudi Arabia
Fertilizer 15	F15	NPK	Germania
Fertilizer 16	F16	NPK	Tunisian
Fertilizer 17	F17	NPK	United States

2.1 Sample preparation

The collected sample underwent to milling process for 2 hours with a porcelain mill with different sizes of porcelain balls. The result powder sieving by 2mm meshes to get rid of the coarse suspended material with sample and obtain a homogenous sample free from impurities that may affect on measuring process. The samples dried in the controlled oven at 100 ^{o}C to remove the moisture and have a constant weight then cooled in desiccators. The sample was left in preservative bags (polyethylene plastic sealed bag) for about 28 days to reach the secular equilibrium condition between ^{238}U and ^{232}Th long-lived radionuclides and its parent daughters. To measure the background radiation of the environment, the homogeneous samples were transported to a new sealed bag and left for about 30 days.

2.2 Measurements

Measurements of natural radioactivity have been done using the gamma-ray spectrometer that includes a multichannel analyzer connected with NaI(Tl) detector. The led cylinder was used to protect the detector and reduced the background level by a factor of about 95%, while the energy calibration was made for the detector by two source ^{137}Cs (0.662 MeV) and ^{60}Co (1.333 MeV).

Spectroscopy analysis: The activity concentrations of radionuclide were determined in Bq/Kg. The activity of ^{40}k was determined from peak energy of gamma at 1460 KeV, while for ^{238}U and ^{232}Th determine from the secular equilibrium and their progenies (^{214}Pb and ^{214}Bi) at energies 295.2 KeV and 315.9 KeV, respectively. The counting time that converting count/s to activity unit (Bq/kg) is19000s.

3. Result and Discussion

3.1 Results

Activity Concentration: The amount of radioactivity in the sample can be determined by the activity concentration as a specific activity following the relation from [4]

$$A_i\left(Bq/kg\right)=\frac{C_i-B.G.}{\varepsilon M_s P_\gamma T} \qquad (1)$$

Where C_i is counting net area under the photo peaks, i represents the fertilizer sample, $(B.G.)$ is background count below, ε denotes absolute energy efficiency for the detector at a specific energy of gamma, $(P\gamma)$ is an absolute γ- transition or emission probability of the specific gamma-ray,(T) is the measurement time of counting inside the detector in(s) and (M_s) is dry of each sample weighted mass in the container in (kg). The specific activities of ^{238}U, ^{232}Th, and ^{40}K and their corresponding uncertainties for samples are represented in Table 2. ^{40}K concentration has value dominated for several samples. The variation in values of concentrations of the radionuclide may due to the chemical formula of fertilizers. The values and average values of each nuclide are shown in fig. (1). The Uranium concentration average value (79.66 Bq/kg) above the global limit, while for ^{232}Th and ^{40}K (30.52 and 181.27 Bq/kg) are less than the worldwide recommended limits reported by UNSCEAR (2008) [5] (35, 35, and 370 Bq/kg, respectively). The variation coefficient shows some data with relatively high and lower values. The high values represent a heterogeneous distribution for data while the lower relatively values indicated homogeneous distribution.

Table 2. Radionuclide specific activity in fertilizer samples.

Sample code	Specific Activity in (Bq/kg)		
	^{238}U	^{232}Th	^{40}K

^{40}K (181.27 Bq/kg) and lowest one for ^{232}Th (32.46 Bq/kg). To measure the degree of asymmetry tail distribution.

of the radionuclide, the skewness has positive values and near zero, while the kurtosis has negative values, i.e. the distribution follows the normal one.

Radiological Hazards Effects Evaluation**:** Different radiological indices were estimated to determine the hazard of natural radioactivity in samples. The calculated values were compared with the universal values that represent safety limits.

3.1.1 Radium Equivalent Activity Appreciation

Since the distribution of radionuclide is not uniform with real activity level in the samples, the radium equivalent (Ra_{eq}) is a single radiological hazard index need to determine because of its ability to give a good explaining of radiation protection for human comparing the limits of fertilizer that must be maximum less than 370 Bq/kg to keep the dose of gamma-ray below 1.5 mSv y^{-1} (UNSCEAR, 2000) [6]. The main formula to compute this parameter is [7]:

$$Ra_{eq} = A_U + (1.43A_{Th}) + (0.077A_K) \quad (2)$$

whereA_U, $A_{Th,}$ and A_K are uranium, thorium, and potassium concentrations, respectively. The above equation is based on the assumption that 370 Bq kg^{-1} of ^{226}Ra, 259 Bq/kg of ^{232}Th, and 4810 Bq kg^{-1} of ^{40}K produce the same gamma-ray dose rate. The radium equivalent is related to both the external γ-dose and the internal α-dose from radon and its progeny. Fig. (2) represented the frequency distribution where analysis has been done for all samples and showed a normal (bell-shaped) distribution.

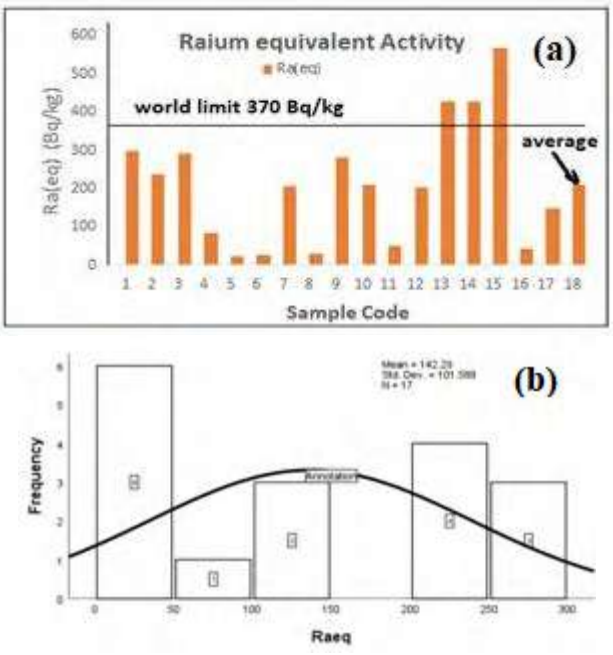

Fig. 2. (a) bar chart (b) normal distribution shapes of Ra(eq) for all samples.

3.1.2 Absorbed Dose and Effective Dose Appreciation

The use of fertilizers in agriculture is a possible source of exposure for the workers in sites and that may increase radionuclide exposure. By applying the following relation one can convert the measured activities of U, Th, and K into doses according to UNSCEAR, 2000 [7] using the same factors to give the absorbed gamma rate in the air at 1m above the ground level[9]:

$$D_{abs}(nGyh^{-1}) = (0.462A_U) + (0.621A_{Th}) + (0.042A_K) \quad (3)$$

The results were shown in Table 2 and figure (3). the limit recommended by UNSCEAR (2000) [7.]

The estimation of annual effective dose (AEDE) according to UNSCER(2008) [5]it must be taken into account by converting the coefficients from (D_{abs} in nGy.h^{-1})) in the air using conversion factor (0.7 Sv Gy^{-1}) to (AEDE in mSv.y^{-1}) with indoor occupancy factor (fraction of time spent indoor (0.8) and outdoor (0.2)). The AEDE from gamma radiation from ^{226}Ra, ^{232}Th, and ^{40}k in the fertilize samples was calculated from [5]:

$$AEDE(mSv) = D_{abs}(nGyh^{-1}) \times 8760h \times O \times C\,(\text{mSv/ nGy}) \quad (4)$$

Where *O* is the occupancy factor and C is the absorbed to the effective dose conversion factor for adults (0.7 x 10^{-6}Sv/Gy). AEDE in all samples for gamma radiation from natural nuclide is varied from

to with mean value of, as shown in table()all studied samples of fertilizers are less than the recommended limiting value of 480 μSv y^{-1} [5].

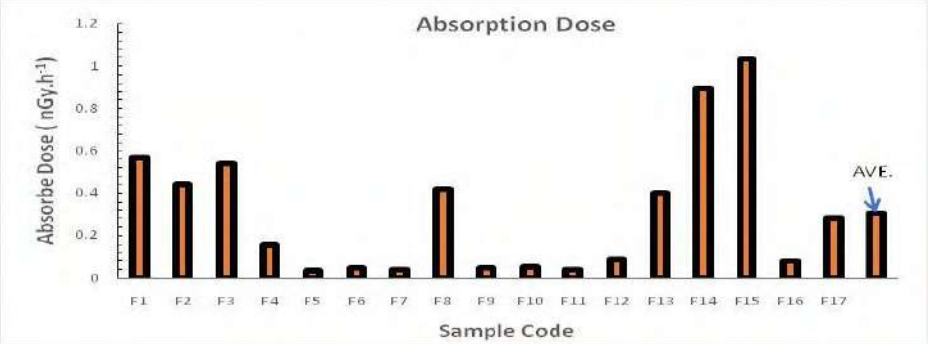

Fig. 3. Absorption Dose values with their average value.

3.1.3. Gamma-ray Index

This index is used to estimate the hazard level of gamma radiation from the fertilizer samples that may harmful by damaging the human body cells. This index limitation according to European Commission Guidelines [8] must be ($2 < I_\gamma < 6$) when increasing the annual effective dose to 1*mSvy*$^{-1}$[9] while $I_\gamma \leq 0.5$ corresponding to *0.3mSvy*$^{-1}$and $I_\gamma \geq 0.5$ corresponding to 1 *mSvy*$^{-1}$. It can be calculated from [10]:

$$I_\gamma = \frac{A_U}{300} + \frac{A_{Th}}{200} + \frac{A_K}{3000} \qquad (5)$$

The results and average value are represented in Table 2 and Fig. 4. Four samples from all the measured samples had a radioactivity level index of more than 1, which lead to avoid using because give an exposure effective dose of more than *1mSvy*$^{-1}$ for whom to deal with this production.

3.1.4. Internal Level Radiation Index (Alpha Radioactivity)

When radon gas is released from samples there is an alpha particle were emitted causes alpha radiation. The index I_α can be calculated from [11]:

$$I_\alpha = \frac{A_U}{200} \qquad (6)$$

It should be less than the maximum permissible value of I_γ for radium concentration 200 Bq/kg. This index must be less than unity and the results of fertilizes samples show varied values from 0.0345 to 1.043 with a mean value less than 1. The higher sample value is F10 (Nitrogen -Urea (EFC).

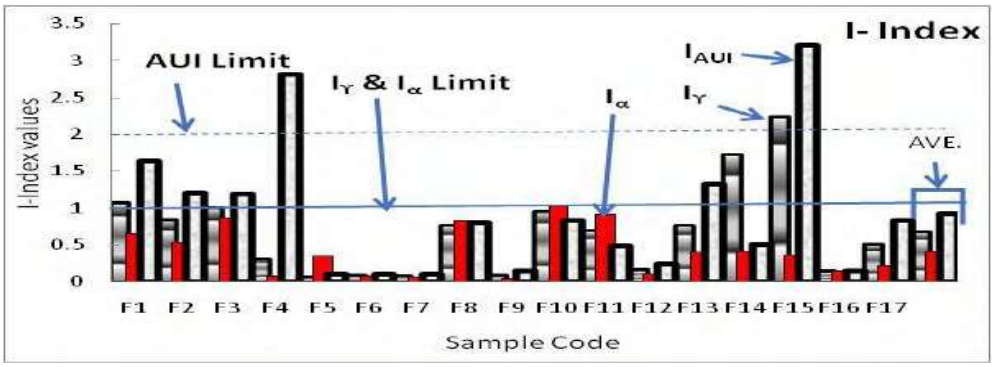

Fig. 4. Radiation hazard indices with limitations and average values.

3.2 Radio hazard indices

Analysis of various known radiological health hazard indicators in radiological studies were used to find a safer conclusion. To assess the radiation risk associated with tested samples, the following indicators were identified.

3.2.1 External and internal hazard indices

To provide information about safe levels of internal exposure to radon and its daughter that have a short-life, the internal index (H_{in}) must be in the value less than one to keep the radiation hazards low. The index can calculate from [12]

$$H_{in} = \left(\frac{A_u}{185}\right) + \left(\frac{A_{Th}}{259}\right) + \frac{A_K}{4810} \qquad (7)$$

The external index (H_{ex}) is an assessment of the natural risks of gamma and is used to evaluate the radioactivity of a substance. H_{ex} represents exposure to external radiation associated with gamma from radionuclide. This index evaluated as following and should also less than one UNSCEAR (2000) [7]:

$$H_{ex} = \left(\frac{A_u}{370}\right) + \left(\frac{A_{Th}}{259}\right) + \frac{A_k}{4810} \qquad (8)$$

3.2.2. Excess Lifetime Cancer Risk (ELCR)

The probability of cancer developing over a lifetime human at a certain exposure level. This indicator gives a value of expected numbers of cancers in limiting people's numbers when exposed to specific carcinogenic at a specific dose. An increase in ELCR led to increase in developing leukemia, breast, and prostate cancer. The ELCR can be evaluated using the equation [13]:

$$ELCR = D_{eff}(AEDE) \times DL \times R \qquad (9)$$

Where DL is the duration of life (approximately 66 years) and RF is a fatal cancer risk factor in (Sv^{-1}) with a value of 0.05 as in ICRP-60 [15].

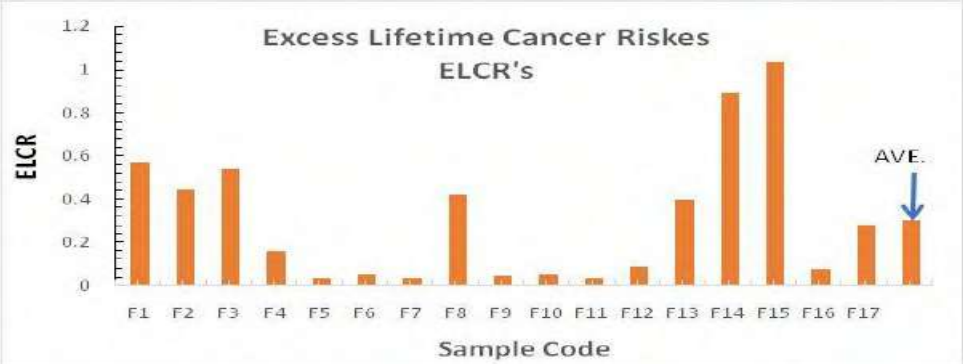

Fig. 5. Excess Lifetime Cancer Risks with the average value.

3.2.3. Activity utilization index (AUI)

The calculation of absorbed dose in the air can be active by using a transfer factor. For this purpose, the activity utilization index building up and calculated using the relation [14]:

$$A_U\,50(Bq/kg)f_U + A_{Th}\,50(Bq/kg)\,f_{Th} + A_K\,500(Bq/kg)f_K \qquad (10)$$

Where f_U, f_{Th}, and f_K are the fraction contributions to the total dose rate in the air because of gamma radiation from the studied natural radionuclide f_U = 8.09%, f_{Th} = 47.98%, and f_K = 43.92%. The main limitation of this index is less than 2 for the annual effective dose(AEDE) (<0.3 mSy/y) [15]. The sample F15 recorded the highest value for this index (3.207) while the average value within the limit.

3.2.4. Clark value $^{232}Th/^{238}U$ concentration ratio

This ratio will give an indicator for the samples collected from a markets regions have either higher or lower uranium concentration to be economic for uranium mining and extraction UNSCEAR(2000).

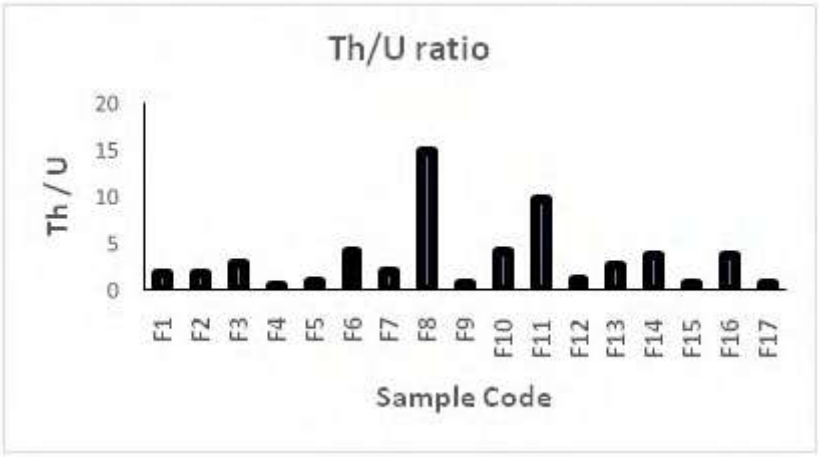

Fig. 6. Th /U ratio.

3.3 Statistical Analysis

To understand the multivariate correlations between radionuclide concentrations and other parameters, Pearsons, descriptive and cluster technique analysis had been carried out through the " Statistical Program of the Social Science (SPSS/PC-IBM) [16].

3.3.1 Pearson's Coefficient Matrix

This method measure the linear relationship between any two continuous parameters. From Table 5, significant correlation is in the bold (") represent the good correlations lies among (0.5) and (1) between any two-parameter and the table show high positive correlations with perfect monotonic relation coefficient (1)**.** The high values correlation of AEDE (in, out) with other parameters was represented while^{238}U has a weak correlation with ^{40}K and AUI. The negative sign in the matrix appears just for Th/U parameter that means the three parameters (Th, ELCR, and AUI) are in the opposite direction**.**

Table 5. Pearson's correlation coefficient matrix for radionuclide and the determined hazard indices of measured parameters.

code	^{238}U	^{232}Th	^{40}K	Ra_{eq}	D	AEDE in	AEDE out	I_γ	I_α	H_{in}	H_{ex}	ELCR	AUI	Th / U

3.3.2. Cluster analysis

Hierarchical cluster analysis is the method used by grouping similar radiometric characters [17] that fall into the same class to have a clear up for the relationships between all parameters and find optimal grouping within each group, and calculate the Euclidean distance for each parameter. The cluster statistics performed based on Pearson's correlation coefficient by the dendrogram shown in Fig. 7 according to Uranium concentration were parameters grouped in the cluster as it present in a population that can be divided into clusters to get the whole population information. It is clear in Fig. 7 there are three clusters, the first represented by samples (1,2,3,4,5 and 6), the second for (7,8,9, and 10), and the third cluster for equal clusters (11,12,13,14,15 and 16). These groups have different areas.

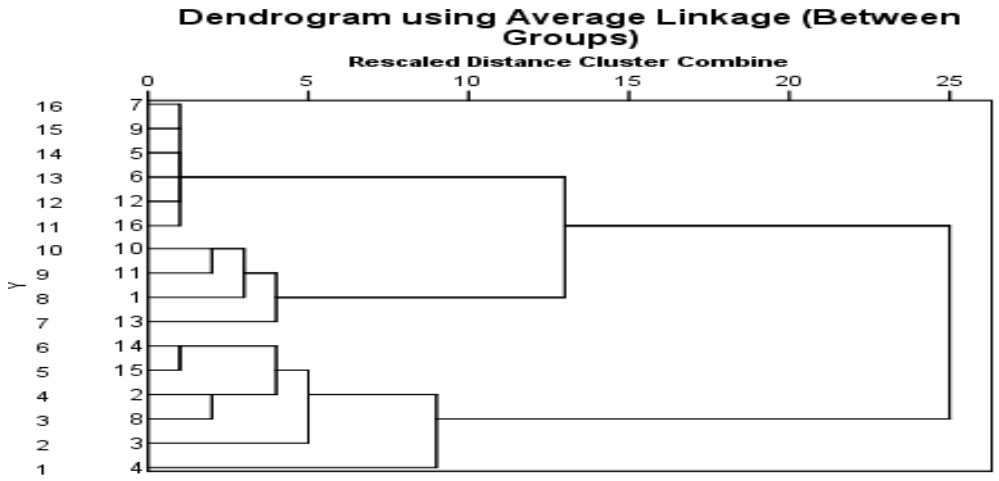

Fig. 7. Dendrogram using Centroid Linkage for classifying parameters with uranium concentration in the fertilizer samples.

3.3.3. Descriptive statistics analysis

From Table 6 the ^{40}K concentration present high average value (496 Bq/kg) than other parameters and twice the uranium average value (209 Bq/kg) with variation coefficient (33.01%), less variation for ^{232}Th (6.16%). This variation coefficient represents the dispersion of the data compared with other parameters variation uranium reach 48.57%.

Table 6. Descriptive statics of the parameters.

4. Conclusion

Natural radioactivity of ^{238}U, ^{232}Th, and ^{40}K in different types of fertilizers was measured. The average specific activities in samples are in the global limits unless the^{238}U is higher than the recommended limit of UNSCEAR 2008. (35Bq/kg). The radiological hazard indices measurement includes radium equivalent activities, external and internal indexes, gamma index, absorbed radiation,

and annual effective doses of the fertilizers. From all of these results, we deduce that the number of fertilizers that showed high radioactivity should be decreased and used with precautions.

Abstract. In the present work, the specific activity of different types of milk powder samples from various foreign origins in the local markets was studied. For this purpose, (HPGe) detector was used. The results showed that Miedo sample (Jordanian origin) had the highest quantities of A_U, A_{Th} and A_k equal to respectively (18.690, 25.070 and 183.500) Bq/kg respectively. All the specific activity and parameters are less than their corresponding allowed limits, and hence no health risk they possess.

Keywords: milk powder samples**,** specific activities**,** (HPGe) detector.

1. Introduction

Radionuclides in air or water may also input food chain. For instance, plants are capable of absorbing radionuclides from water in the same way of absorbing different minerals. When humans and animals drink water, some of the radionuclides in the water will remain in their bodies. Radionuclides from air may settle on the surface of plants. When animals consume the plants, they ingest the radionuclides that have settled from air or have been absorbed from the water. Animals and plants that will eventually be food for humans thus provide a pathway for radionuclides to move via the environment to humans [1]. Milk products and milk are important components of diet in many countries. Milk is one of the few foods produced over large areas and collected on a daily basis. Its composition is almost identical all over the world, and it is easy to collect a representative specimen that can be analyzed in dried or liquid forms [2]. Milk is likely to be contaminated by radioactive. Contamination of milk can be greatest when cows are grazing, but even if cows are kept indoors, contamination of milk may also occur by means of inhalation of radionuclides [3].

2. Experimental part

2.1. High purity germanium system (HPGe)

In the present study, (HPGe) detector with energy resolution of (2.6 keV) at energy (1332.6 keV) for ^{60}Co and efficiency of 40% was used. The high purity N-type semiconductor detector with (3×3) inch was used to study the characteristics of geometry closed end coaxial. (HPGe) detector is kept cold by immersing it in a liquid-nitrogen vessel at (-196˚C) to reduce the leakage current to the acceptable levels.

The detector is surrounded by lead shield of about 10 cm thickness in order to reduce the background radiation.

Figure 1. (HPGe) system

2.2. Radiation Hazard indices Calculation

activity concentrations[5]:

$$A = \frac{NET}{\varepsilon * I_\gamma * m * t}$$

NET: net peak area under the specific peak corrected for the background
A: activity concentrations of the sample with unit Bq/kg, ε : Energy efficiency,
m: mass of sample (kg), t: measurement time (7200 sec.).
Radium Equivalent (Ra_{eq})[5]:
Ra_{eq} (Bq/kg) = (1.43A_{Th}) + (0.077A_K) + (A_U)
Where:
A_U, A_{Th} and A_K are the specific activity concentrations of U-238, Th-232 and K-40 respectively.
2.2.3 Absorbed Dose Rate (D_γ) [6]:
D_γ (nGy/h) = 0.604A_{Th} + 0.462A_U + 0.0417A_K

Annual Effective Dose Equivalent [7]:
$(AED)_{in}$ (mSv/y)= D_γ (nGy/h)×10^{-6}×8760 h/y×0.80×0.7Sv/Gy
$(AED)_{out}$ (mSv/y)= D_γ (nGy/h)×10^{-6}×8760 h/y×0.20×0.7Sv/Gy
External (H_{ex}) and Internal (H_{in}) Hazard Indices [8]:

$$H_{in} = \frac{A_U}{185} + \frac{A_{Th}}{259} + \frac{A_K}{4810} \leq 1$$

$$H_{ex} = \frac{A_U}{370} + \frac{A_{Th}}{259} + \frac{A_K}{4810} \leq 1$$

Activity gamma Index (I_γ) [9]:

$$I_\gamma = \frac{A_U}{300} + \frac{A_{Th}}{200} + \frac{A_K}{3000}$$

3. Results and Conclusions

The aftereffects of the present work were outlined in Table 1. The most elevated estimation of A_U, A_{Th} and A_k was found in Nido sample (Jordanian origin) to be (18.690, 25.070 and 183.500) Bq/kg respectively. While, the lowest estimation of A_U, A_{Th} and A_k was found in Ancor sample (New Zealand origin) to be (9.420, 10.190 and 76.260) Bq/kg respectively. Figure (2) shows the average estimation of (20.785±3.6 Bq/kg and 24.695±3.3 Bq/kg), respectively. The present outcomes have demonstrated that the estimations of A_U, A_{Th} and A_k in fertilizer samples were less than the recommended values of (35, 30 and 400) Bq/kg respectively [10].

The most elevated estimation of the parameters [Ra_{eq}, D_γ, $(AED)_{in}$, $(AED)_{out}$, H_{in}, H_{ex} and I_γ] was found in Ancor sample to be (29.864 Bq/kg, 13.687 nGy/h, 0.067 mSv/y, 0.017 mSv/y, 0.106, 0.081 and 0.108) respectively. While the lowest estimation of the parameters [Ra_{eq}, D_γ, $(AED)_{in}$, $(AED)_{out}$, H_{in} and I_γ] was found in Nido sample to be (68.670 Bq/kg, 31.429 nGy/h, 0.154 mSv/y, 0.039 mSv/y, 0.236, 0.185 and 0.249) respectively, and with an average estimation of (49.025 Bq/kg, 22.411 nGy/h, 0.11 mSv/y, 0.027 mSv/y, 0.167, 0.132 and 0.178) respectively. All the values of the specific activity and parameters were less than their corresponding allowed limits, and hence no health risk is considered.

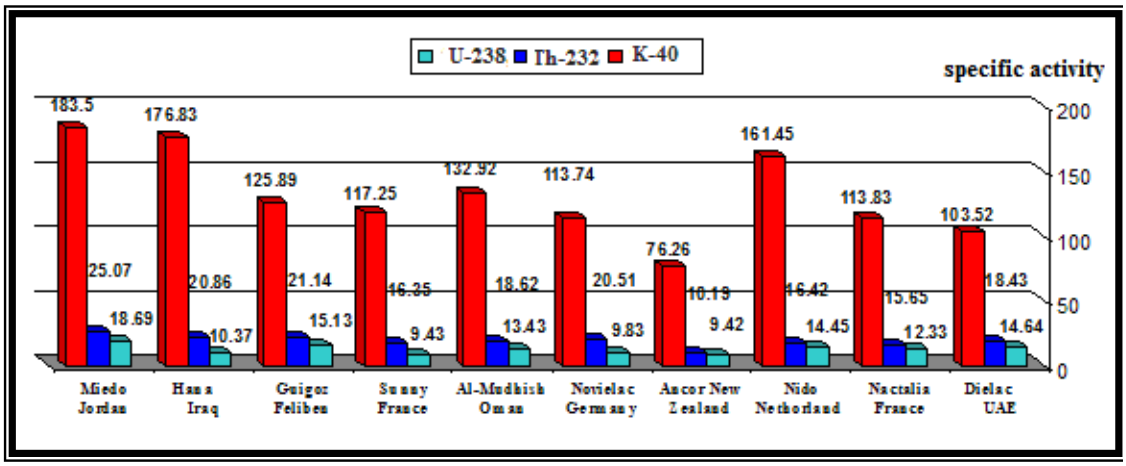

Figure 2. Specific activity of (^{238}U, ^{232}Th and ^{40}K) for all studied milk powder samples

Table 1. Specific activities of ^{238}U, ^{232}Th and ^{40}K with some other parameters [Ra_{eq}, D_γ, $(AED)_{in}$, $(AED)_{out}$, H_{in}, H_{ex} and I_γ] in all milk powder samples

Worldwide average [10]		35	30	400	370	55	1	1	1	1	1

4. Conclusions

The results of the present work were concerning the values of the specific activity for (^{238}U, ^{232}Th and ^{40}K) and determining the parameters [Ra_{eq}, D_γ, $(AED)_{in}$, $(AED)_{out}$, EAD, I_γ, H_{in} and H_{ex}]. All the above values were found to be lower than their corresponding allowed limits.

Abstract. In the present work, three radioactive elements of radium were used to produce radon gas and ^{222}Rn was measured by three different techniques (Rad-7 detector, Scout detector and CR-39 detector). It was found that the ^{222}Rn gas measured by Rad-7 detector is closer to the real readings than other detectors.

Keywords: ^{222}Rn, Scout detector, (CR-39) detector, Rad-7 detector.

1. Introduction

Exposure to ^{222}Rn and its radioactive progeny present in the environment results in a large contribution to an average effective dose received by human beings [1,2]. Natural ^{222}Rn and its airborne progeny can cause a significant internal health hazard, especially when they build up in enclosed areas such as houses, mines and caves. Workplaces may differ from houses in terms of building structure, microclimatic conditions and occupancy factors. Some of the peculiarities of workplaces are: (a) widespread use of ground floor or basements, (b) high probability of finding elevated temperatures and high levels of humidity (c) multi-stored buildings with big entrance hall and (d) presence of air conditioning or forced ventilation aerosols and dust. Such workplace characteristics might result in large aerosols. Such workplace characteristics might result in large spatial and time variations of ^{222}Rn, thus requiring an appropriate monitoring strategy [3,4].

2. Materials and Method

Three radiating elements of radium were used as (107.85Bq, 1734.01Bq and 1734.01Bq). It was placed in a plastic box (see figure 1). After that, Rad-7 detector, Scout detector, in addition to 10 pieces of CR-39 detectors with an area of (1 cm×1 cm) were distributed within the plastic box. The measurement of ^{222}Rn concentration was made every 12 hours using a detector that placed inside a plastic box with (90 cm×90 cm×80 cm) dimensions, and the plastic box was sealed tightly to ensure that the radioactive ^{222}Rn is not escaping outside the plastic box.^{222}Rn emitted from radium element was calculated using equation (1) [5].:

$$E_s\left(Bq * \frac{day}{m^3}\right) = \left[A_{Radium}\left(\frac{B_{q)}}{Vm^3}\right)\right] * T(day) \quad (1)$$

where: $E_{s:}$ the ^{222}Rn gas exposure in radium source.
A_{Radium}: the radioactivity of ^{226}Ra.
V: the container volume (plastic box) in m^3.

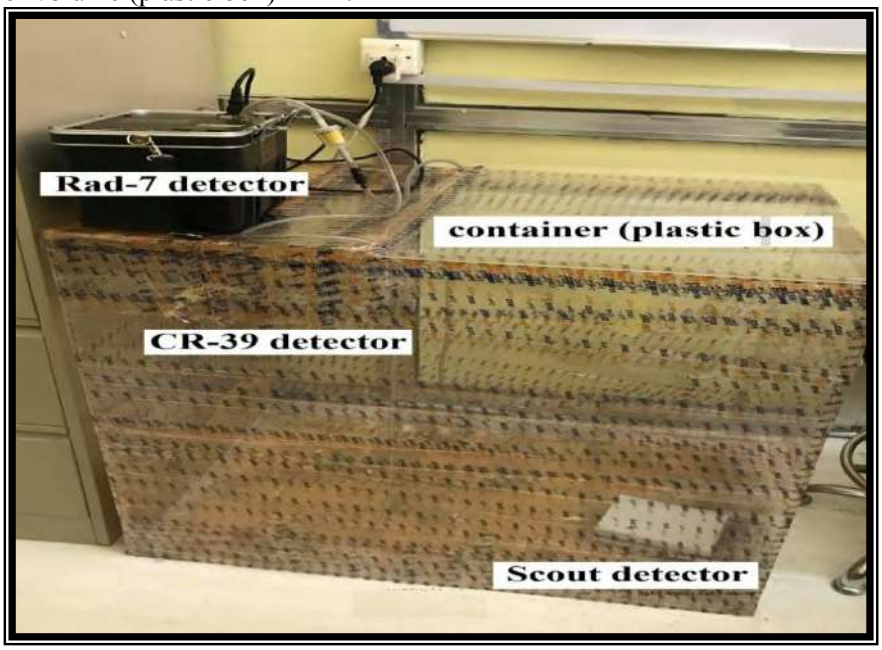

Figure 1. The container (plastic box), Rad-7 detector, Scout detector and CR-39 detector**.**

3. Results and-Discussions

In the present work, ^{222}Rn gas concentration was measured using the detectors (Rad-7, Scout and CR-39) as seen in figure 2 , and a comparison between the results is shown in Table (1). it is noticed that the radon concentration measured using the CR-39 detector increases with increasing the period of exposure to radioactive sources. In addition, we noticed that the values of the Rad-7 detector are closer to the real values of the ^{222}Rn emitted from the radioactive radium followed by the values of the Scout detector and then the CR-39 detector (see figure 3). Rad-7 detector was better than other detectors due to the different measurement technology as it relies on the contrast of the gas flap.

4. Conclusion

The present work has demonstrated that theRad-7 detector is closer to the real values of the ^{222}Rn emitted from the radioactive radium followed by the values of the Scout detector and then the CR-39.

Figure 2. shows all detectors using in the present work

Abstract. This study aims to investigate the characteristics of optical fiber sensors under X-rays radiation. The Radiation-Induced Absorption (RIA) and Radiation-Induced Refractive-Index Change (RIRIC) in the UV-VIS domain were investigated. Single and multi-mode optical fibers (SMFs & MMFs) have been used for this purpose. The outer diameters of these fibers were reduced from (125 to 50 and 55µm for SMF and MMF respectively) via chemical etching process then dipped into (3 wt % concentration) of germanium (Ge) solution to produce the sensing part of the fibers. Due to the applied X-rays radiation, an attenuation of the spectrum and a redshift in peak wavelength were achieved. Both sensors show good responsivity to the applied radiation and the MMFs sensors showed higher wavelength shifting as compared to SMFs sensors.

Keywords: X- rays, optical fiber radiation sensors, Radiation-induced Absorption; Radiation-Induced Refractive-Index Change; Germanium doped optical fibers.

1. Introduction

Most types of radiation are dangerous for living beings when exposed to them. For this reason, real-time remote dose measurements have great necessity. Radiation dosimeters have been applied in wide fields such as nuclear facilities, industrial process controls (X‑ or e‑ beam polymerization), nuclear medicine, and radiotherapy. The usage of traditional electronic dosimeters has some problems like using high power energy, uncertain measurement under radiation due to degradation and changing of measured sensitivity. Furthermore, it is difficult access to very hazardous areas, such as hot cells, high active source storage areas [1]. On the other hand, optical fibers sensors (OFS) present the key feature to be used as radiation detection dosimeters in different fields including space military, industry etc. This is because they have a number of advantages regarding the traditional forms of the data link [2]. The high spatial resolution (parts of millimetres), accuracy, large dynamic range, the cost-effectiveness, sufficient sensitivity, acceptable fading, response linearity, reproducibility, dose rate independence, and immune to electromagnetic radiation. All these characteristics made OFS very suitable choice for radiation detection applications [3]. Two types of OFS's structures can be used as radiation sensors; the first one is the intrinsic sensor which is used as a radiation‑ sensitive material, and a guide for an optical signal passing through it to the detector [4]. This type is frequently used for monitoring the radiation dose of the radioactive waste container[5]. The second type is the extrinsic senor that only acts as a waveguide to deliver the optical signal from transmitter to receiver and the sensing part is spliced or coupled to the waveguide [6]. These types of sensors mostly used in‑ vivo monitoring during radiotherapy [7]. The interaction between fiber material and the applied radiation causes the existence of point defects in fiber core and cladding. Also, this interaction leads to three

macroscopic effects; Radiation-Induced Attenuation (RIA) which increases the attenuation of the signal, Radiation-Induced Emission (RIE) which is responsible for the emission of light and originates from the luminescence of point defects or Cerenkov emission, and finally, Radiation-Induced Refractive Index Change (RIRIC) which is caused by changing the density in the glass or by the RIA via the Kramers-Kronig relations [8][9]. The sensitivity of multimode or single-mode optical fibers exposed to different types of radiations was described in many research. Gerard et al. [2] studied the sensitivity of SMFs under gamma and pulsed x-rays radiation in the IR wavelength range. The tested samples were doped with P (Phosphor), N (Nitrogen), and Ge (Germanium) dopants. A demonstration of the actual ability of a silica -based optical fiber doped with Ge to be used as a thermally stimulated luminescence-mode dosimeter and to confirm its applicability. These fibers have been irradiated with different types of radiation photons, x and gamma rays within a dose range higher than 10 krad, with different dose rates[10].The Thermo-luminescence response of Ge-doped silica-based optical fiber to electron, x-rays and gamma rays had been presented by Entezam et al. [11] they found that the Ge-doped optical fiber with higher core size has a higher sensitivity. Ladaci et al [12] investigated the Ytterbium and Erbium energy level lifetimes versus doses of various radiation types (40 KeV X-rays, 480 MeV protons, 1.2 MeV γ-rays and 6 MeV electrons).Also, they added Cerium ions Erbium-doped fiber to improve its tolerance on RIA effects.The RIA of different doped optical fibers under X-rays at three different temperatures had been studied by Vecchi et al. [8]. They found that the irradiation of both gamma rays and x-rays leads to the same levels of RIA. This result confirmed that these types of optical fiber sensors could be used in dosimetry fields.

In this work, the behaviour and performance of SMFs and MMFs optical fiber sensors with modified cladding under x-ray radiation at different exposure times will be observed and studied.

2. Materials and Methods

Commercially available SMFs and MMFs were utilized as radiation sensors in the measurements technique. The core diameter of the SMF sensor was 10 μm and the cladding diameter was 125 μm, while the MMF has a core diameter of 50 μm and a cladding diameter of 125 μm. The fabrication process of the radiation sensors took place as follows; first, the middle region of these fibers were stripped and cleaned very well with the suitable solution (the length of the stripped region is about 3 cm). After that, the fibers' diameters were reduced via the chemical etching process by immersing them into hydrofluoric acid (HF) diluted with distilled water. The concentration of HF acid was 42 %, this concentration had been diluted by adding distilled water with percentage (1(HF):2 (water)) ml for 45 and 30 min for SMF and MMF respectively. Then the fibers removed from HF solution and dipped into water for three stages to remove any remaining HF solution from the fiber surface. Fibers have been removed from the water and measure the diameter of the fibers after etching. For accurate measurement, the etching procedure is done at room temperature (around 25 ˚C). The obtained diameters were (50 and 55) μm for SMF and MMF respectively. Finally, the etched region of the fibers was dipped in (3wt. %) of Ge solution to generate the sensing part of the sensor.The germanium is a colloidal solution; it was prepared by dissolving Ge powder in toluene liquid. Due to etching process the cladding surface of silica optical fiber becomes rough and contains pores and what is called dangling bonds; these bonds capture Ge nanoparticles and make them settle down inside the pores. Since the stripped part of the fiber is immersed in the solution with caution then the etching process will be equal all over cladding surface, therefore, Ge nanoparticles will adhere equally on the cladding surface According to these steps, the modified cladding fiber sensors were manufactured and submitted as clarified in Figure 1.

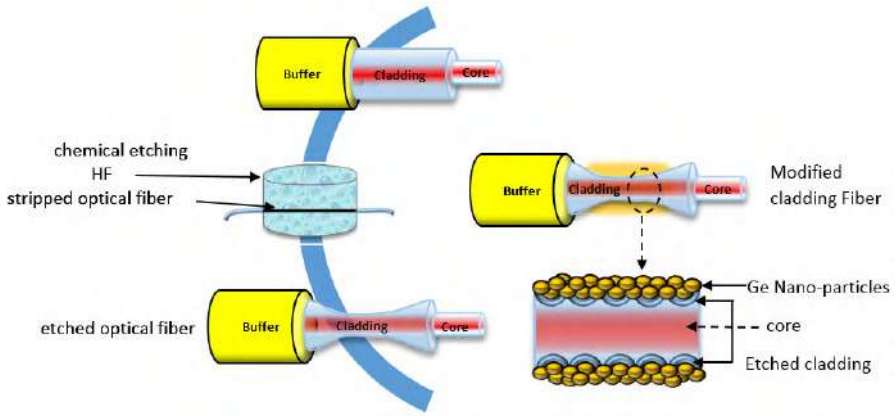

Figure 1. The manufacturing steps of the modified cladding optical fiber sensor.

Figure 2 illustrates the schematic diagram of the experiment to investigate the x-rays irradiation effect on the properties of the transmitted signal. It is worthy to mention that the transmitted signal in the UV-VIS range changes due to the absorption process of the x-rays radiation.

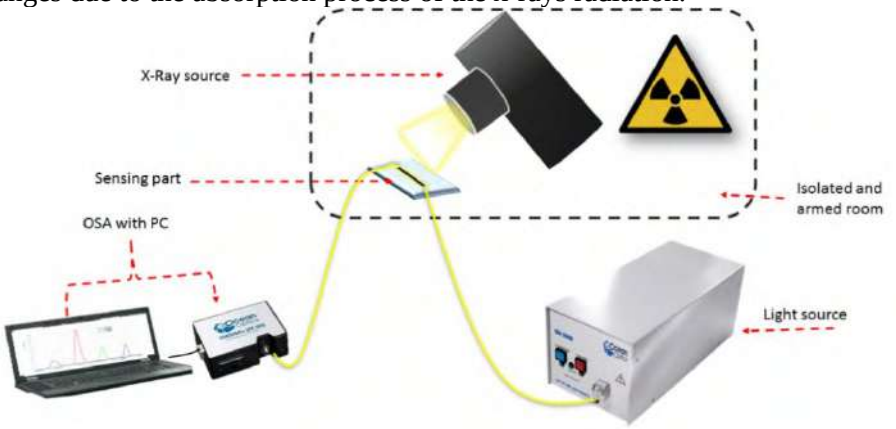

Figure 2. Schematic diagram of the measurement set-up.

The sensing parts of SMFs and MMFs samples placed on a glass slide then inserted inside an isolated armed chamber of the X- ray radiation source (XRD-6000 SHIMADZU) device. This device is located at the material research directorate, ministry of science and technology, Iraq. The exposure angle was (90^{o}) to ensure that all the sensing area exposed to radiation. The distance between the fiber sensor and the radiation source head was (10 cm). The other parts of optical fibers were located outside the chamber and the two ends of each fiber considered as the sensor terminals. The first terminal was connected to the UV-VIS light source (DH-2000 Ocean optics) with range (200-1100) nm as a transmitting signal passing through the sensors. While the other terminal was connected to the spectrometer (Ocean Optics USB- 2000) to record the spectrum online during the irradiation process (real-time measurement). The X-rays were emitted from a Cu tube with the following specifications; (X-rays tube target Cu with Broad Focus (BF 2.7 KW type), the maximum voltage of 60KV, maximum current of 80 mA, and average maximum power of 3 KW). The resulted spectrum of each sample was recorded as (3) measurements within (3) minutes (one measurement each minute) to test the responsivity of designed sensors to low radiation doses.

3. Results and Discussions

As mentioned, earlier the transmitted spectra of both investigated optical fibers sensors were measured and recorded at different x- rays dose rates. The following figures illustrate the output data revealed from this work. Figure (3a, and b) shows the spectral dependence of the measured spectra for the SMF and MMF sensors respectively due to x-rays irradiation.

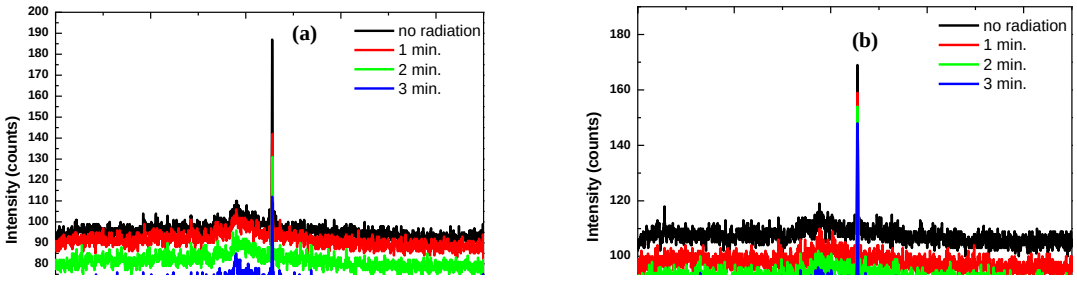

Figure 3. The spectral shape of (a) SMF sensor, (b) MMF sensor.

The above figures show that RIA in both investigated fibers has similar spectral character. For SMF's sensors we can notice that in the VIS spectral region, there is a local sensitivity maximum at around 655 nm from which the induced RIA drops rapidly towards IR wavelengths. Besides, there is another peak with a local minimum around 570 nm as is clear in Figure 3 (a). The same behaviour founds when using MMF's sensors except a new peak found in the range of 255 nm as it shown in Figure 3 (b). The transmitted intensity for all samples decreases due to radiation application attenuation in transmitted intensity increases with the dose rate which is 3 minutes.

Figure (4a, and b) shows the intensity values (intensity attenuation)as a function of radiation exposure time for both SMF and MMF sensors. The RIA sensitivity for SMF sensor was measured through the linear fitting relation between the intensity and exposure time for each peak. The values were (-) 23.1 count/ min and (-)11 count /min for the peaks 650nm and 570 nm respectively with good reliability of 0.93 and 0.99 respectively. While for the MMF sensor the sensitivity values were (-) 6.8 count /min, (-) 8.3 count /min, and (-) 8.7 count /min with reliability values of 0.98, 0.99, and 0.95 for the peaks 650 nm, 570 nm, and 255 nm respectively. The transmitted intensity for all samples decreases due to the attenuation phenomenon that appears in optical fibers due to X-rays irradiation.

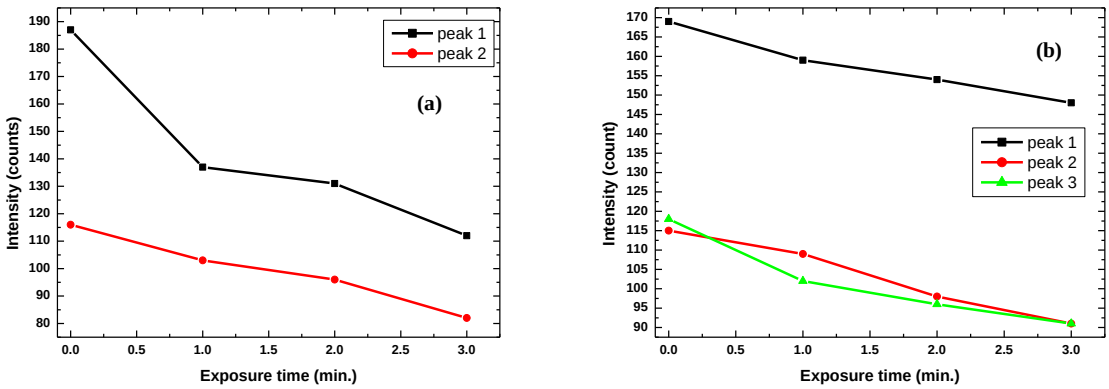

Figure 4. Transmitted intensity as a function of exposure time for (a) SMF sensor, (b) MMF sensor.

One of the most important and effective parameters for any radiation sensor is its wavelength sensitivity. The wavelength sensitivity was measured through the linear fitting relationship. In this work, sensitivity was measured for both modified cladding SMF and MMF sensors. SMF sensor shows a wavelength sensitivity of 8.1 pm/min and 25 pm/ min with good reliability 0.96 and 0.95 for the peaks 650 nm and 570 nm respectively. On the other hand, MMF sensor showed a very high sensitivity of 112 pm/ min and 50 pm/ min with good reliability 0.95 and 0.96 for the peaks 650nm and 570 nm respectively. The third peak that appeared in the output spectra of the MMF sensor at 255 nm suffered from a blue shift due to radiation application, and the sensitivity for this peak was (-) 10060 pm/ min with a reliability of 0.95.

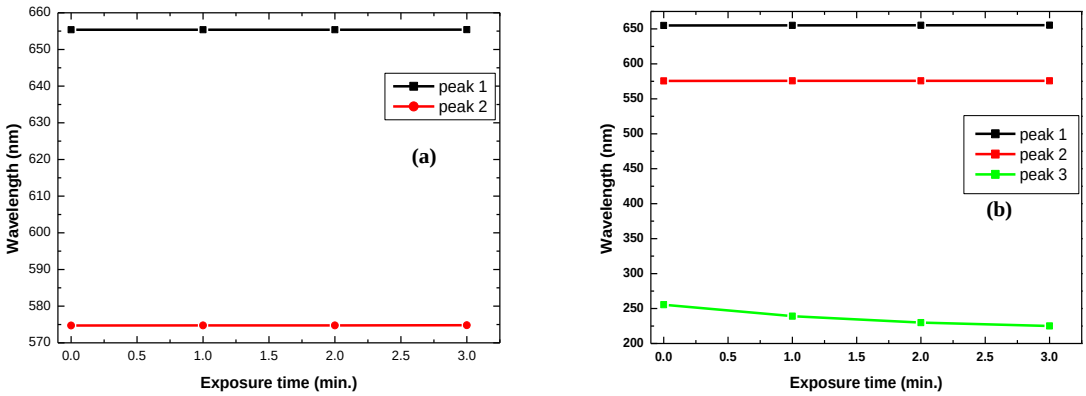

Figure 5. Peak wavelength as a function of exposure time for (a) SMF sensor, (b) MMF sensor.

According to these results, SMF sensors have higher intensity sensitivity than MMF sensors. This could be explained as follows; for MMF sensors with their large core, the effects of the light-guiding on changing signal intensity are small, while the changing in wavelength due to radiation application was higher for them as compared to SMF sensors. Investigating the behaviour and performance of SMF and MMF sensors with smaller diameters decreased by the chemical etching process was achieved. However, this procedure resulted in leaking some of the transmitted light signals outside the cladding known as an evanescent wave. These leaked waveforms act as a field around the cladding material and interacts with the dipping material (germanium) lead to generation of point defects that change fiber structure, and thus change its refractive index. Ge nanoparticles plays very important role in sensing

process since Ge and Si are isoelectronic elements having therefore the same number of electrons. Therefore, Ge-related point defects have a similar structure as those related to Si, but replacing Si with Ge atoms. In Ge-doped fibers, Ge-related defects are dominant over Si-related defects because they are generated in a more efficient way. In Ge-doped fibers, the RIA has been found to monotonously increase with dose (D) before reaching a saturation level. It is worthy to mention that the submitted optical fibers sensors have different layers and compositions (silica and germanium) and therefore they are subjected to different stresses. Hence, due to what mentioned earlier, the structural modification, defects generation, and layers stress, all these factors can have spatial distribution and in return modify the guiding properties of the optical fibers. The changing in wavelength due to radiation application was higher for MMF sensors. This is because the interaction between the incident radiation and fiber materials lead to inelastic scattering. The origin of scattering is due to the interaction of light with the excitation of the medium. According to quantum theory approach, the interaction is between the quanta of light (photons) and quanta of medium excitation which are phonons. This is true for the low light intensity levels, but for the strong excitation of the medium due to the high intensity of light, the semi-classical wave theory turns to be more appropriate to describe the scattering process. For an inhomogeneous medium, the scattering process removes some photons of the incident light and produces scattered photons that might be shifted in direction, phase and frequency in this work the shifting was in frequency (wavelength). The incident photons give or receive energy to or from the medium, leading to scattered photons shifted in frequency by definition, the components of the scattered light which are shifted to lower frequencies are known as Stokes components while those components which are shifted to higher frequencies are known as anti-Stokes components. This scattering leads to produce new photons with new phase and frequency. This could be the reason behind we get two different shifting red and blue in MMF sensors.

4. Conclusions

This work is aim to perform an initial assessment of the possibility to utilize optical fibers as radiation sensors; modified cladding SMFs and MMFs had been used for this purpose. X-rays source with an exposure time of 3minutes source was employed as the radiation source. Both fibers exhibited a similar spectral character of decreasing the transmitted light and shifting in peak wavelength due to radiation. In spite of small exposure radiation time (due to Lab protocols) but both sensors exhibited good response. The SMF sensors showed a higher intensity sensitivity, while the MMF sensors showed a higher wavelength sensitivity. The presented sensors could be very useful in medical applications like monitor low doses of ionising radiation, radiation dose real-time measurements, and radiotherapy applications.

E-mail: malakmuhsin0@gmail.com

Abstract. The focusing of charged particles beam passing through the transport system is affected by many parameters and depends on the elements that used in the transport beam systems. In this study, a permanent bending C-shape magnet is used to investigate the effect of the geometrical configuration parameters of bending magnet on the focusing of the passing charged particles beam. This investigation is implemented via the method of the matrix's representation. The results showed that the edges of the bending magnet have opposite focus in the horizontal and vertical planes of beam motion. The deflecting angle effect appeared as a rotation of the phase space ellipse of the charged particle beam without focusing of this beam. The results also, showed that the focus of the charged particles beam is unlike in both horizontal and vertical planes of beam motion.

Keywords: beam transport systems, bending magnet, phase space ellipse.

1. Introduction

Beam transport system usually contains of focusing, deflection, acceleration and sometimes additional energy or momentum selection elements. Often these devices are magnetic elements, although at low energy beam, electrostatic elements are used. Quadrupoles and bending magnets with free drift spaces are the main elements of any beam transport system. The dipole magnet produce bending and dispersion effect, while quadrupoles produce focusing effects, the drift spaces is regions where there is no force acting on the particle motion. The performance of beams can be studied in two aspects either by tracing a large number of individual particles (single particle dynamics) or by studying the transfer properties of bundle (the collective effects caused by the electric and magnetic fields generated by the beam itself), in the present study the charged-particles treated as a bundle of particles, linear phase space [1].

Importance of studying the beam transport systems lies in determining the role of each element of the system in the focusing, accelerating and transporting beam particles from the source to the target with more control on particles beam properties.

Any charged particles beam can be represented in six-dimensional phase space (ellipsoid) that enclose all the particle in the beam, these particles expected to occupy the volume enclosed by the ellipsoid, and each point representing a possible ray. The total sum of all phase points, or the phase space volume, is generally referred to as the phase space occupied by the beam [2].

The projection of the ellipsoid in two dimensions is named phase ellipse, this phase space ellipse shape and orientation change as the beam moves along the beam line.

2. Bending Magnet

The main function of bending magnet, mostly named as mass analyzer, is bend the path of the particle on a curve with radius (R) which leads to clearing the natural particles from charged particles beam, then, focusing these particles into the central orbit of the magnet. In such this analyzer the ions are accelerated as focused beam with same kinetic energy. And then the ions are deflected according to their masses, the magnetic field bend the lighter ions more than the heavier ones which leads to separate different ions. In this study a C- shape magnet was used to transport ions generated by plasma source. Figure 1 illustrates the longitudinal section for the design of the magnet used in present study.

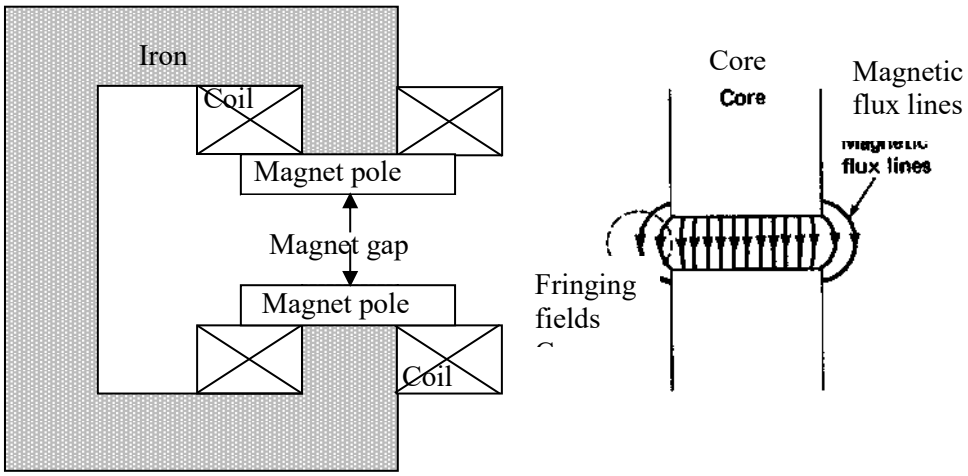

Figure 1. Longitudinal section of bending magnet.

The bending magnet consist basically of two regions, the good field region in which the magnetic field stay particularly constant and the other region is the fringing field which the magnetic field decreases to approach zero in a transition region far from the edges of the magnet, extending from each side of the terminal cross section for a distance depends on the order of the width of the gap between the poles [3].

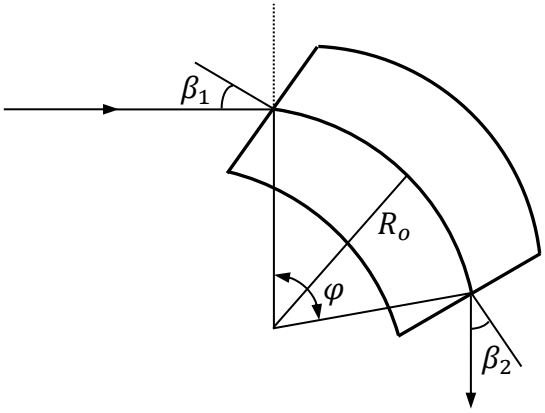

Figure 2. Main parameters of bending magnet.

From configuration of bending magnet there are three angles play important role in the focusing of the charged particles beam passing through the magnet. Deflecting angle (φ), as indicates in Figure 2,

which is defined as the angle between the line connecting the center of particle orbit and points of entrance and exit of central trajectory [4] this angle cause a rotation of the beam, this angle in some magnets with range of (45°-90°) [5, 6], while in others (135°) or (270°) [4,7].

The entrance angle (β_1), as shows in Figure 2, is defined as the angle between the normal to magnet pole boundary and the beam center line in entrance space, and the exit angle (β_2) is the angle between the normal and the beam line on the exit side.

The edge of deflecting magnet poles acts as focusing regions that are resulted by a non-homogenous magnetic field. These regions are called a fringing field. So at the entrance and exit angle are very important parameters for the focusing beam passing through the deflecting magnet.

The motion of beam through each region in beam transport line can be describe in term of R-matrix, the total R-matrix of the magnet region is:

$R_{x,y}\ (\text{total}) = R_{x,y}(\text{exit edge}).R_{x,y}(\text{inside the magnet}).R_{x,y}(\text{entrance edge})$

In other form [8,9]

$$R_{x,y} = \begin{bmatrix} 1 & 0 \\ \pm\frac{\tan(\beta_1-\psi)}{R_o} & 1 \end{bmatrix} \begin{bmatrix} \cos k_{x,y}l & \frac{1}{k_{x,y}}\sin k_{x,y}l \\ -k_{x,y}\sin k_{x,y}l & \cos k_{x,y}l \end{bmatrix} \begin{bmatrix} 1 & 0 \\ \mp\frac{\tan(\beta_2-\psi)}{R_o} & 1 \end{bmatrix} \quad (1)$$

where ψ is angle of fringing field related to nature of bending magnet manufacturing, $k_{x,y}$ is the wavenumber for the horizontal and vertical oscillations respectively, related to field index (n) which take value $0 < n < 1$ and l is the path length inside the bending magnet.

$$k_x = \frac{(1-n)^{1/2}}{R_o}, k_y = \frac{(n)^{1/2}}{R_o} \quad (2)$$

$0 < n < 1$

$$l = \varphi R_o \quad (3)$$

The sign $(+)$ for horizontal plane and $(-)$ for vertical plane

The linear phase space matrix (σ) is

$$\sigma = \begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{12} & \sigma_{22} \end{bmatrix} \quad (4)$$

The relation between σ-matrices in two positions of the beam line (between $\sigma_{x,y}(\text{in})$ and $\sigma_{x,y}(\text{out})$), is giving by the following inverting equation

$$\sigma_{x,y}(\text{out}) = R_{x,y}\sigma_{x,y}(\text{in})R^T_{x,y} \quad (5)$$

For phase space ellipse:

$x_{max} = \sqrt{\sigma_{11}}$ the maximum spatial extent of ellipse which is called by beam envelope.

$x'_{max} = \sqrt{\sigma_{22}}$ the maximum angular divergence of the beam within the phase ellipse.

3. Results and Discussion

Present design of beam transport system was include the regions; extraction region (plasma source), first drift space region, bending magnet, and then second drift space region. The angles of bending magnet were changed as, the deflecting angle (φ) values in the range (30°-90°) while the entrance and exit angles (β_1) was take values in the range (5°-20°).

The effect of deflection angle (φ) on the phase space ellipse of charged particles beam, at constant values of entrance and exit angles of bending magnet , shows in figures (3 and 4), which indicates that the increasing of (φ) leads to more rotation for the charged particles beam in both horizontal and vertical planes. Also, the slope of phase space ellipse became negative beyond ($\varphi = 60^o$), which means converge (focusing) of charged particles beam. One could be note that the area of the phase space ellipse remained constant for all values of (φ).

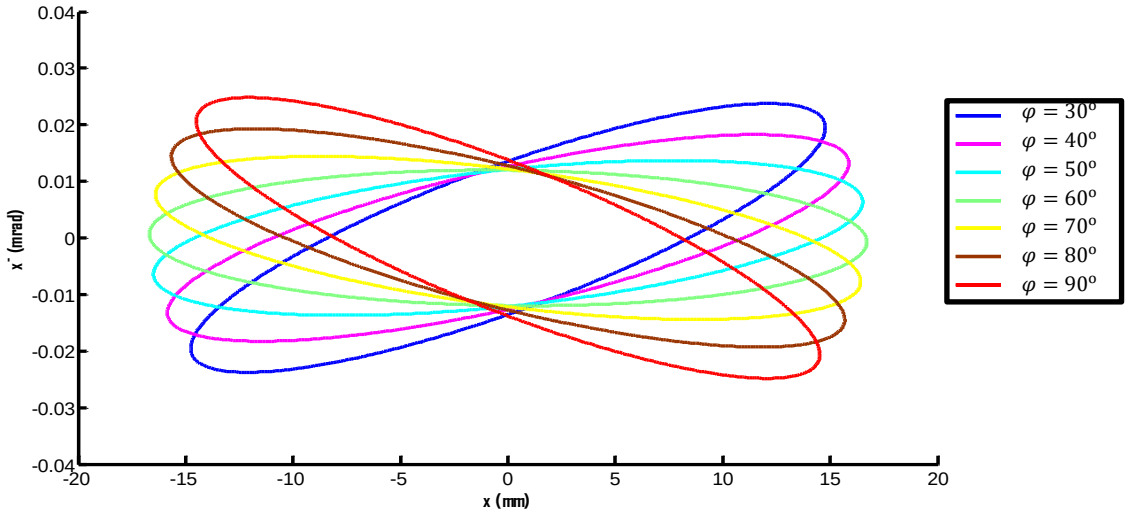

Figure 3. Phase space ellipse of horizontal plane for different deflecting angles.

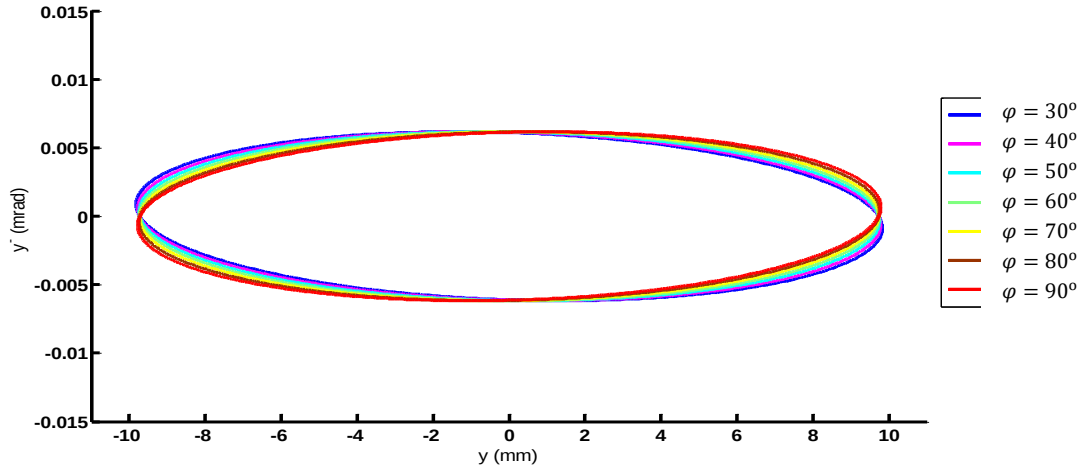

Figure 4. Phase space ellipse of vertical plane for different deflecting angles.

The effect of entrance edge angle (β_1) on the phase space ellipse of charged particles beam for horizontal and vertical planes shows in Figures 5 and 6, at constant values of deflection and exit angles of bending magnet, which indicates that the entrance edge angle (β_1) of the bending magnet acted as a thin lens, as the distance does not increase through it, but changes the focus of the charged particles beam and that increasing the entrance edge angle increases the focus of the charged particle beam. The entrance edge angle (β_1) acts as adiverge thin lens in the horizontal plane, while in the vertical plane acts as a converging thin lens. Also, the area of the phase space ellipse remained constant for all values of (β_1).

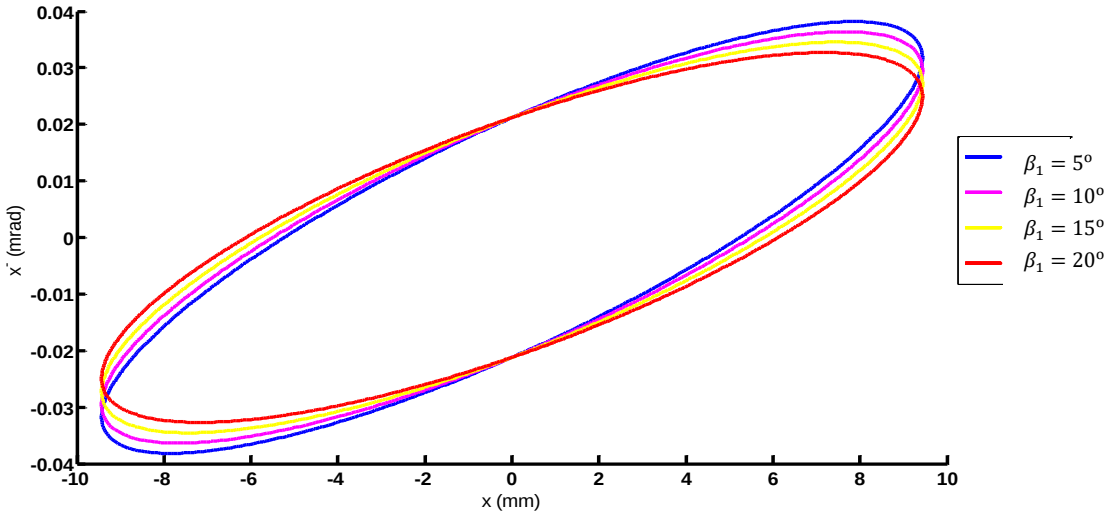

Figure 5. Phase space ellipse of horizontal plane for different entrance angles.

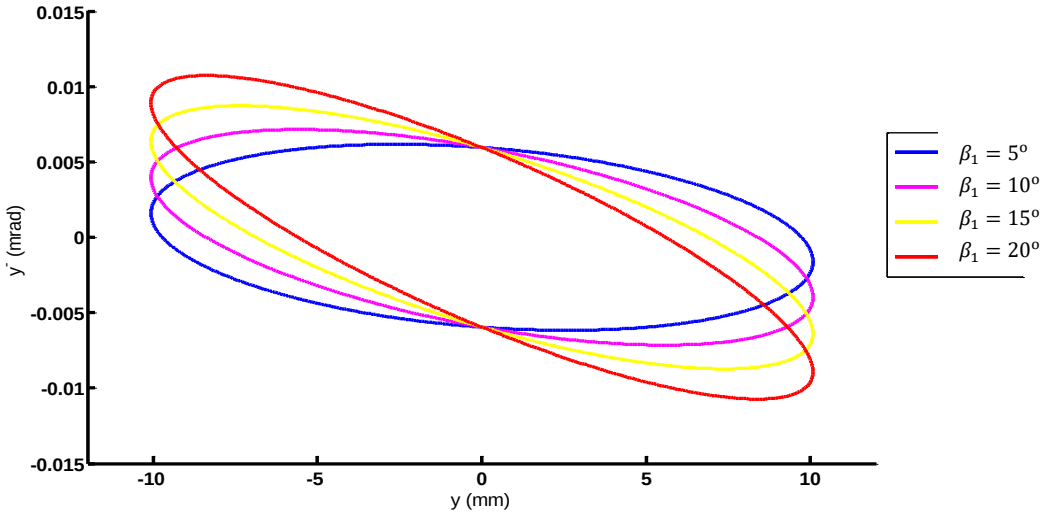

Figure 6. Phase space ellipse of vertical plane for different entrance angles.

As entrance angle, the effect of exit edge angle (β_2) on the phase space ellipse of charged particles beam for horizontal and vertical planes shows in Figures 7 and 8, at constant values of entrance and deflection angles of the bending magnet, indicates that the entrance edge angle (β_2) of the bending magnet acts as a converging thin lens in both horizontal and vertical planes. The increasing of (β_2) cause an increase in the converging of charged particle beam

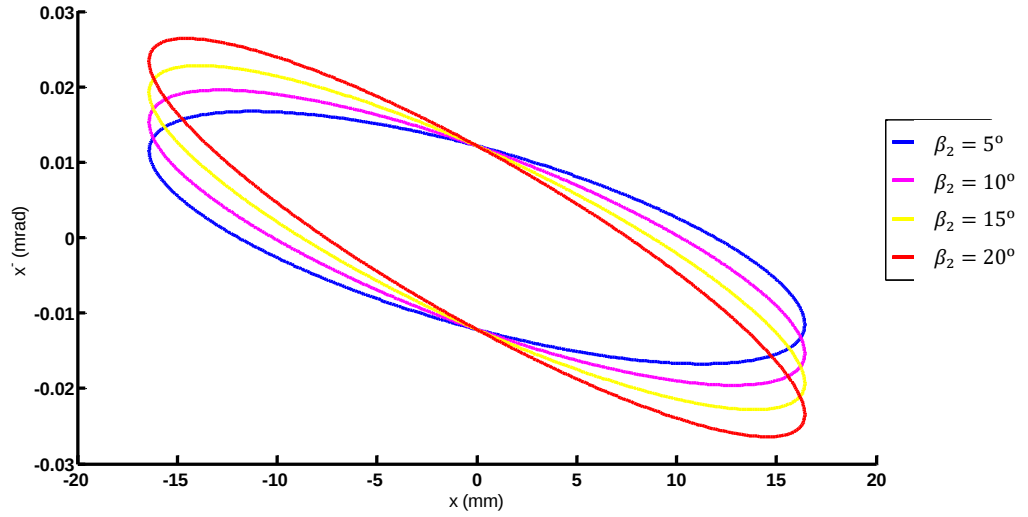

Figure 7. Phase space ellipse of horizontal plane for different exit angles.

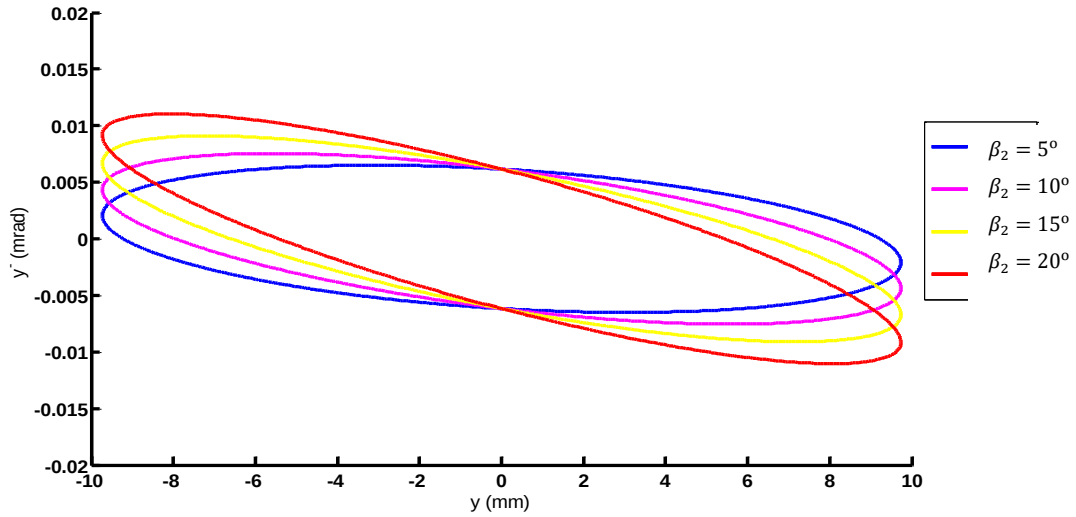

Figure 8. Phase space ellipse of vertical plane for different exit angles.

It is useful to study the envelope of charged particles beam passing through the transport system by plotting the maximum displacement of particles at every region along transport system. Beam envelop is indicate the focusing regions along the beam path.

From the results of phase space ellipse for horizontal and vertical planes, for different configurations for transport system, shown in Figures (3-8), the best configuration of bending magnet that gives best focusing for beam transport passing through it, found to be $\beta_1 = \beta_2 = 20^o$ and $\varphi = 90^o$.

Figures 9 and 10 show the beam envelope along beam transport system best configuration that obtained in present work for horizontal and vertical planes. These figure show that the best values of

β_1, β_2 and φ gives minimum values of distance (focusing) in both horizontal and vertical planes at same time.

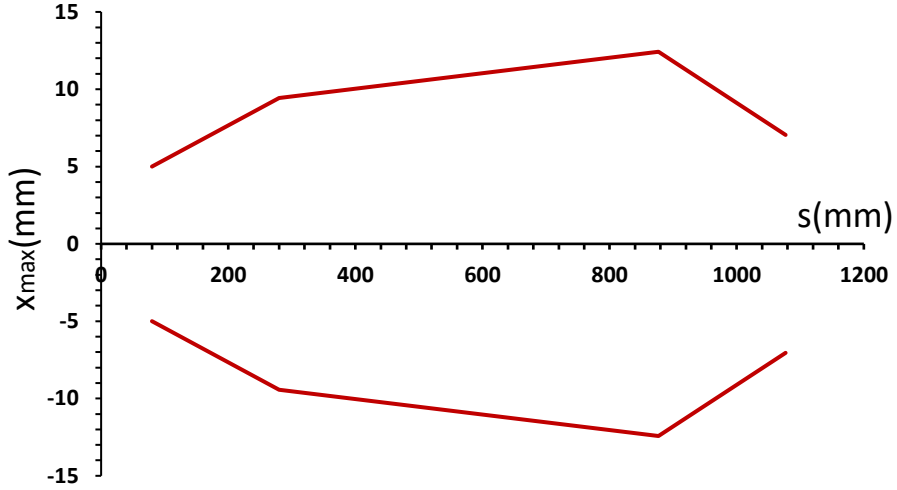

Figure 9. Beam profile in horizontal plane at $\beta_1 = \beta_2 = 20^o$ and $\varphi = 90^o$

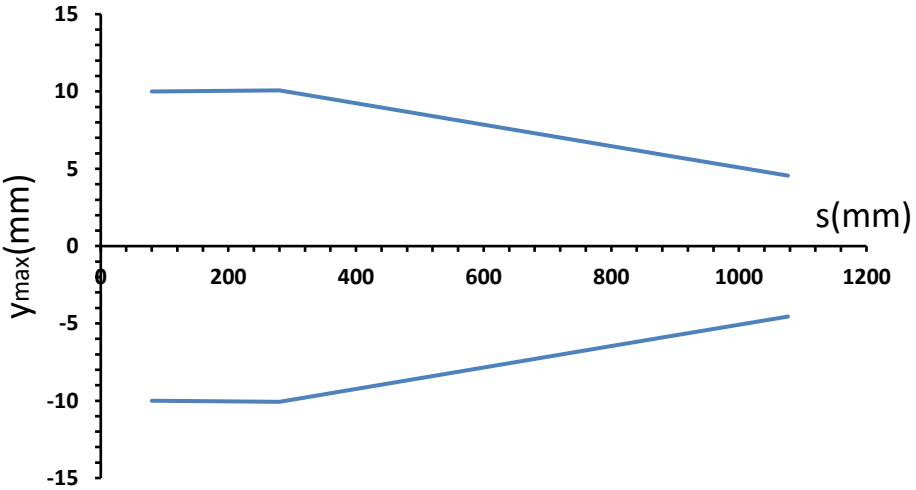

Figure 10. Beam profile in vertical plane $\beta_1 = \beta_2 = 20^o$ and $\varphi = 90^o$.

4. Conclusions

Focusing of the charged particles beam vary with bending magnet geometrical parameters. The edges of bending magnet act as thin lens with opposite focusing in horizontal and vertical planes of beam motion. The deflecting angle of the bending magnet leads to clear rotation for charged particles beam without focusing of charged particles beam. The focusing of the charged particles beam is unlike in both horizontal and vertical planes of beam motion. Best focusing of beam obtained at $\beta_1 = \beta_2 = 20^o$ and $\varphi = 90^o$.

Abstract. In this work, Graphene oxide (GO) was synthesized by Hummer's method using graphite rod. Used organic chemical materials to active (GO – COOH) for esterification reaction between the graphene oxide carboxylic acid group and the Polyethylene glycol (PEG) hydroxyl group. Graphene oxide (GO) was conjugated to PEG4000 (medical polymer).The composite (GO – PEG) characterization by XRD, FTIR, UV- Vis and AFM. In UV- Vis GO showed a sharp peak at 275 nm whiles the peak of (GO – PEG) appear at 284 nm. A strong OH bond appear in Fourier transforms infrared spectroscopy (FTIR) spectra, C –H bond of (GO – PEG) also showed. In XRD pattern GO have a sharp peak appear at $2\theta = 11.83^{\circ}$ that related to 001 with d-spacing of 7.76 Å while functionalization of GO – PEG 4000 conform by broad peak at $2\theta = 23.38^{\circ}$ with d-spacing of 3.8 Å. Atomic force microscopy (AFM) images, GO image shows Graphene oxide sheet with main grain size is 24.41 nm, In GO – PEG4000 shows aggregation of Graphene oxides with PEG4000 the main grain size increase with functionalize to 287.04 nm.

Keyword. PEGyltion, Graphene oxide, Hummer's method, PEG 4000.

1. Introduction

The Graphene oxide (GO) layer has been considered one of the most promising carbon derivatives in material science over the past few years and has demonstrated excellent physical properties, biocompatibility and chemical stability [1]. Since Graphene, a two-dimensional (2D) mono- atomically thick planar layer, was first reported in 2004 [2]. In recent years, a variety of research groups have documented biomedical and physical applications of Graphene, such as drug loading and delivery [3].This drugs used instead chemotherapy as anti-cancer drugs [4]. GO comprises a number of hydrophilic oxygen-containing functions, such as epoxy, hydroxyl and carboxyl groups, which have improved dispersibility in solvents as well as provide reactive sites for more functionalization by specific interactions [5]. Therefor, this led to evolution of smart Nano carrier – based drug delivery system which also known as SDDSs. This system promises to apply drugs to unique and targeting cancer types [6]. The reaction between the medical polymer and Nanoparticles was controlled using a polymerization method and this was first mentioned by Speiser et al. [7]. Among this nanoparticles (GO), has many functional groups on its composition, allowing Graphene to be stable suspension in water and bound to other drugs and polymers [8]. Polyethylene glycol is the most stabilizing agents and most studies one, The immune system's effect of phagocytosis on Graphene oxide can be prevented by using PEG which is due to decrease uptake by reticuloendothelial system (ERS) (which is the part of immune system that consist of the phagocytic cells) and because its high aqueous solubility it used widely in SDDSs [9]. In

this work Graphene oxides GO was synthesis by Hummer's method and then PEG was conjugated to the GO to produce strong ester interaction between PEG and GO which is called PEGylated Graphene oxide (GO-PEG) and characterization it with different techniques.

2. Experimental section

2.1. Chemical material

99.995%, Natural graphite rod, $KMnO_2$99%, $NaNO_3$ 99.5%, H_2O_2, 32%,HCl 37.5%, EDC hydrochloride C6H17N3–HCl, N– Hydroxysuccinimide (98%) from (Sigma-Aldrich), (H_2SO_4, 98%) from (LOBA Chemie), NaOH (99%) from Dae-Jung, PEG 4000 from HI Media, Diethylether $(C_2H_5)_2O$ (98%) from Thomas Baker.

2.2. Synthesis of graphene oxide (GO)

The most economical way used to synthesis graphene oxide is Hummer's method. In which 1g of graphite rod milling into form powder and added with sodium nitrate in sulfuric acid were mix in an ice bath for 45 min. After that 3g of $KMnO_2$ added gradually at temperature 35 C°. The thick blend stirred for 1 day. $KMnO_2$ is reduced by adding (H_2O_2, 32%). 5 ml of (HCl, 37.5%) and DI water used to wash the thick blend. The resultant was dried at 75 C° for 5h to get the graphene oxide.

2.3. Preparations of PEG 4000 - functionalized GO

The activation of (GO – COOH) was began by esterification reaction between the Graphene oxide carboxylic acid group and the PEG hydroxyl group which is necessary for PEGylation of GO thus; 120 mg/ml of NaOH was solved in 20 ml in DI and added to 20 ml of GO suspension 2mg/ml, the suspension sonication for 1h and stirred for 3h. The pH of suspension was reduced by added 3ml of HCl then it was centrifuged twice 4000 rpm for 30 min to produced (GO – COOH) (GO carboxylic acid). The residue was wash with water twice.

The (GO – COOH) was diluted by 10 ml water to active (GO – COOH) 400 mg of EDC and 240 mg of NHS was added to (GO – COOH) then For (GO – PEG) 1500 mg of PEG4000 was added to the resultant and stirred for 24h.

Final step, the resultant was centrifuged and washed by DI water. UV-Vis and FTIR used to Characterization the resultant to identify whatever the carboxylation and PEGylation were conjugated.

3. Result and dissection

PEGylation (GO – PEG) was Characterization by UV – Vis spectroscopy, Fourier transforms infrared spectroscopy (FTIR), X-Ray diffraction (XRD), and atomic force microscopy (AFM). Figure1. Illustrates a simple schematic of synthesis of graphene oxide from graphite and the GO- PEG bonding and structure.

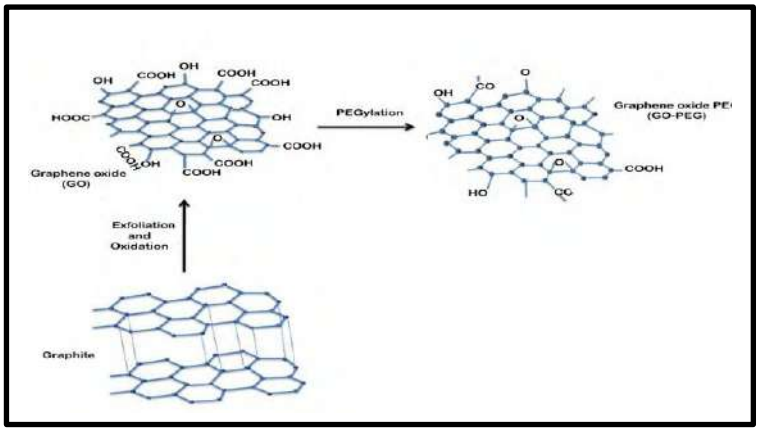

Figure1. Structure of GO- PEG.

3.1. UV – Vis analysis

Figure 2. Showed the spectra of GO and (GO – PEG), the blue line indicate the GO spectra at 275 nm which represent the absorptions bands that related to electronic transition π – π* for C-C (aromatic rings) and transition n – π* for C=O in the Graphene oxide. The red line represent the (GO – PEG) that shifted to 284 nm which confirms the synthesis of (GO – PEG) [10, 11].

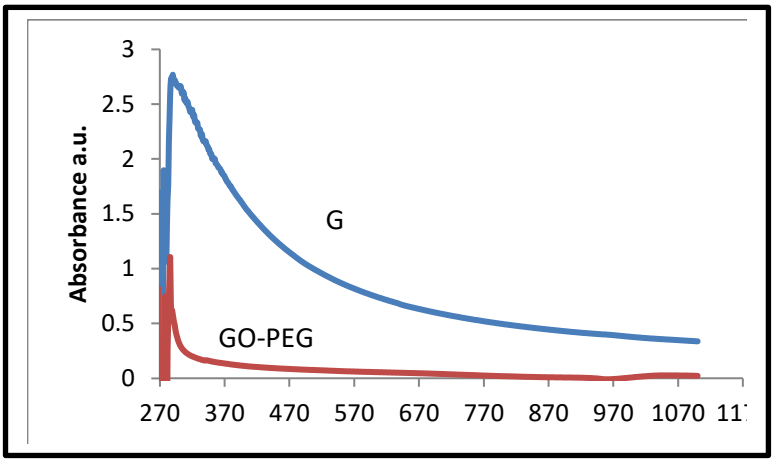

Figure 2. UV-Vis spectrum for GO and GO-PEG.

3.2. FTIR analysis

Figure 3 displays FTIR spectra of GO and (GO – PEG). In the figure, blue line represent the GO sample, and the peaks at 3338 is stretching related to OH, while1618, 1382 and 1026 cm^{-1} are C=O groups in carbonyl and carboxyl [12]. Peak at 1724 cm^{-1} is related to C=C and peaks at 1066 and 1382 related to C-O [13]. While in case of (GO – PEG) the peak at 3338 cm^{-1} shifted to 3427 cm^{-1} also appearance of C-H at 3920 cm^{-1} which proved that GO conjunction to PEG, also the appearance of C=C, C-O and C=O at 1641, 1390,1107 cm^{-1} was also identified [14].

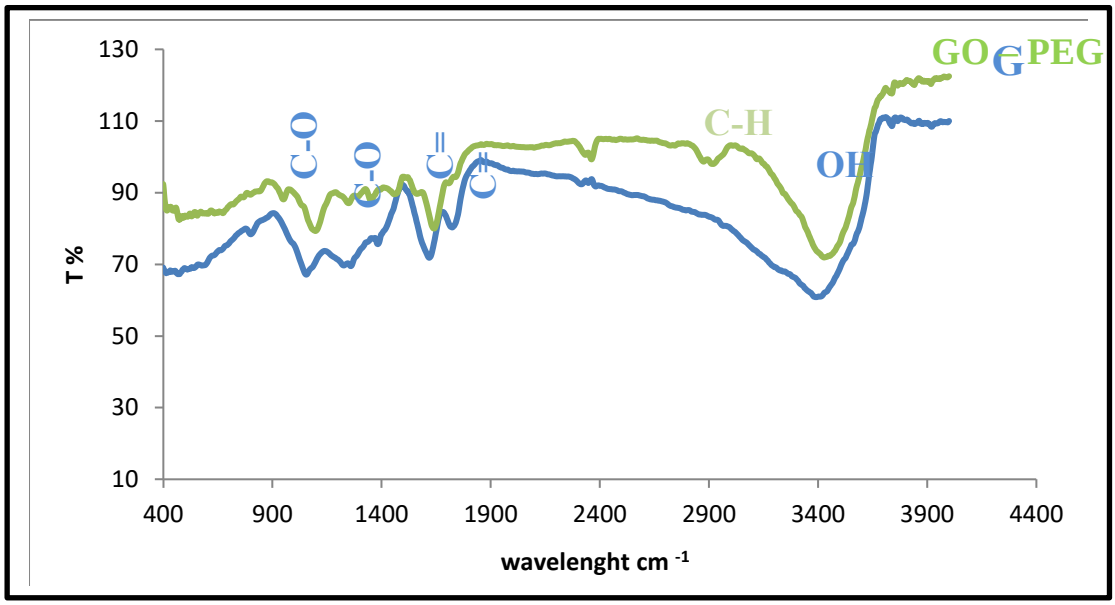

Figure3. The FTIR spectrum of GO and GO- PEG.

3.3. XRD DIFFERACTION

Blue line in Figure 4 represents the XRD pattern of GO which a sharp peak appear at 2θ = 11.83° that related to 001 with d – spacing (7.76 Å) and conform the hexagonal structure of graphene oxide while the red line indicted to functionalization of GO – PEG 4000 with broad peak at 2θ= 23.38° with d – spacing (3.8 Å) which is results from functionalized while the peak of GO disappear because GO has an effect on the structure of the PEG molecular chain in the crystal lattice , disturbing the order of its crystallization. This decreases the crystallinity of PEG and result in an effective conjugation of PEG to GO Nano-sheets by ester bonding. [14].The orientation (001) determine by high score plus program.

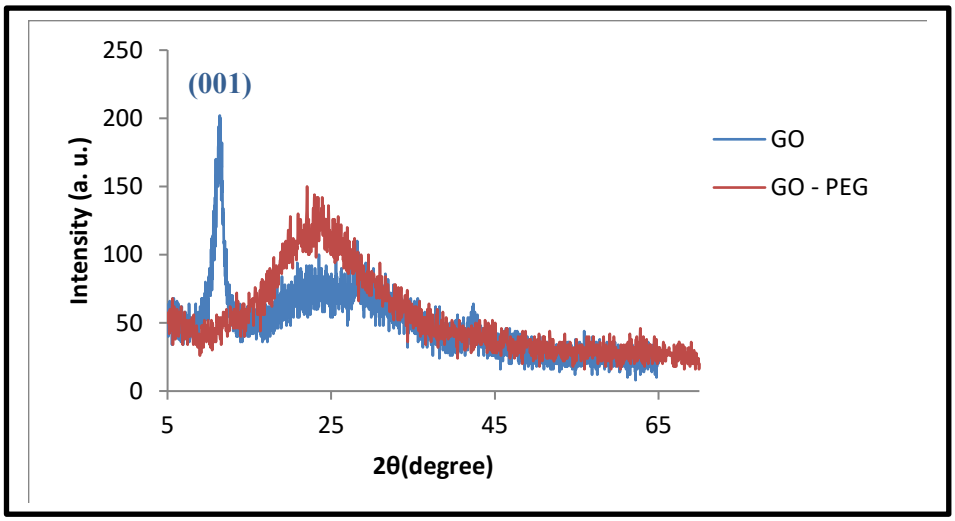

Figure 4. The XRD pattern for GO and GO – PEG4000.

3.4. AFM analysis

Images in Figure 5 Show the AFM analysis of GO and GO – PEG4000 in GO image shows graphene sheet with main grain size is 24.41 nm which conform the Nano size of synthesis. In GO – PEG4000 shows aggregation of graphene oxide with PEG4000 the main grain size increase with functionalize to 287.04 nm [15].

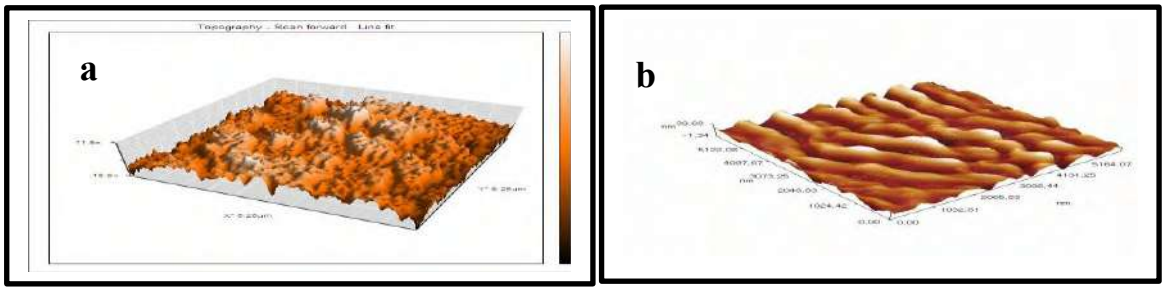

Figure 5. Surface images by AFM for a) GO and b) GO – PEG4000.

4. Conclusion

Graphene oxide Nano - particles successfully synthesized with mean grain size 24.41 as sheet form which analyzed by AFM. GO shows high absorbance in UV region with stretching related to OH at FTIR spectrum. PEG4000 conjugated with GO which is seen in C-H at 3920 cm-1 at FTIR spectrum

with broad peak in XRD diffraction. The last form of conjugated GO – PEG4000 shown in AFM image as aggregation viscous.

Evaluation of the radiological hazard in some dried fruit and grain samples in Iraqi Markets by Using of gamma ray Spectroscopy

Evaluation of the radiological hazard in some dried fruit and grain samples in Iraqi Markets by Using of gamma ray Spectroscopy

Athraa Naji Jameel

Physics Department, College of Education, Mustansiriyah University, Baghdad, Iraq

E-mail: athraanaje@yahoo.com

Abstract. The activity concentrations of ^{226}Ra, ^{232}Th and ^{40}K have been measured by using of gamma spectroscopy for fifteen samples fall under the consumed food group (six type of dried fruit and nine types of grain) at local markets in Baghdad. The average of activity concentration values of ^{40}K, ^{232}Th and ^{238}U were 324.4±28.5 Bq/Kg, 3.66±0.20 Bq/kg and 3.44±0.58 Bq/kg, for the dried fruit samples, 302.3± 98.9, 4.8±1.5 and 4.29 ±1.4 Bq/kg, respectively. For the grain samples, radiation hazard indices, the annual effective dose, internal and external risk, lifetime cancer, and the doses of ingestion, were all doses values within the international borders allowed. Thus, Food the dried fruit and grain in Baghdad is safe for human consumption and it has no heath effect.

Keywords: Radioactivity, Dry fruit, Excess Life Time Cancer Risk, ingested effective dose.

1. Introduction

Natural happening radioactive matter (NORM) is found in soil. NORM may be moved from soil to plants. Thus, every type of meals may also have a few quantity of radioactivity in it. Most types of food have the following isotopes and their daughter products, ^{238}U, ^{232}Th and ^{40}K [1]. The primary pathways for the transfer of radionuclide's to humans are meals crops. Natural radionuclides are transmitted and cycled by natural processes and the various extreme environmental booths by entering into ecosystems and human meals chain [2]. Radiation doses acquired due to the intake of meals may be calculated from the quantity of radionuclide deposited on foodstuffs, the activity concentration of particular radionuclide in meals according to unit deposition, the intake rate of the meals merchandise and the dose according to unit activity ingested [3, 4]. Most people around the world rely on grains, legumes and foods from cereals in their diet. The normal amounts of radioactivity in our daily food are important to estimate. However, a study of the concentration of natural radioactivity in foodstuffs was conducted in different countries [5, 6]. There are many Global research interested by popularity of radioactive pollutants in exported and imported meals and The appearance of match potassium ^{40}K in all meal samples and the intake of match potassium ^{40}K in exported and imported meals over those years did not target any radiation dose above the global recommended limit [7-9].

In addition, plant absorption varies from species to species; thus the consumption of different meal items is a secondary supply of variability [10, 11]. Therefore, the objective of the present study is to

evaluate the activity concentrations of ^{40}K, ^{238}U and ^{232}Th in different foodstuffs in the region and to estimate the effective dose of ingestion for individuals consuming local foodstuffs in the area.

2. Materials and methods

2.1. Preparation of Samples

Six samples of the different dried fruit and nine samples of the grain were collected from the Iraqi markets. Samples have been placed in an oven for dried it and crushed to attain a homogeneous powder, The homogenized samples were packed into Marinelli Becker and sealed for 30 days to achieve a secular equilibrium, Table 1 Shows the name, code and the country for the dried fruit and grain samples.

2.2. Measurement of samples

^{238}U, ^{232}Th, and ^{40}K analysis in dried fruit and grain samples using a 100 percent relative efficiency crystal dimension NaI (Tl) detector of 3×3. Manufactured by Ortic in the U.S.A., the module has 4096 channels and a working voltage of 695V. Samples are measured for 24 hours (86400 s). Made in the United States of America (U.S.A.). Three standard sources (^{60}Co, ^{133}Ba, and ^{137}Cs) were chosen from the samples. These isotopes were placed at a distance of 4cm from the top of the detector inside the shielding. The spectrum of standard elements used to calibrate the NaI(Tl) system as shown in Figure 1 and the efficiency curve between the energy and efficiency of all energy from standard sources as shown in Figure 2 are shown.

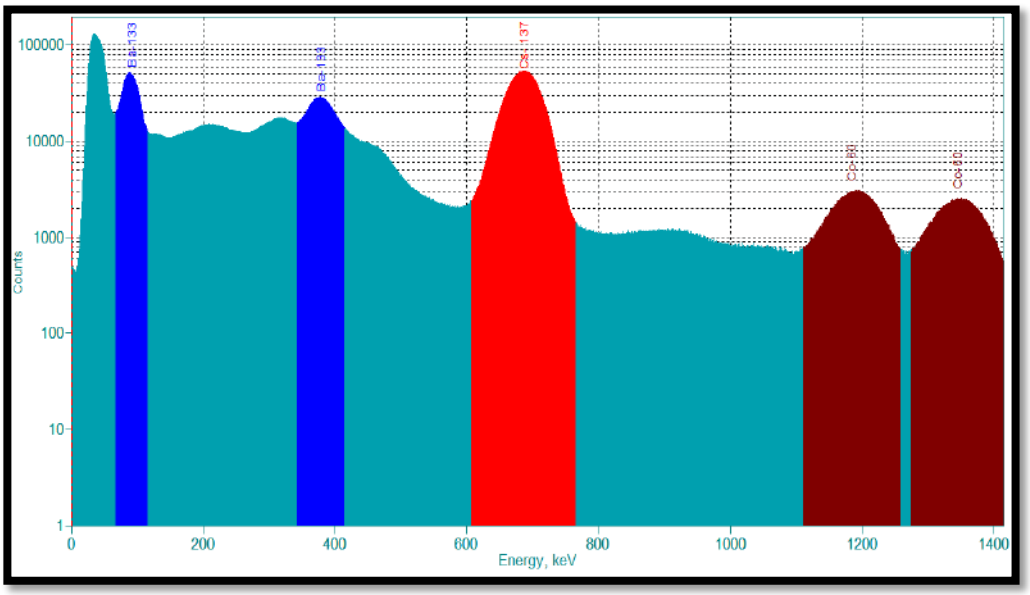

Figure1. A spectrum of standard elements use to calibrate NaI(Tl) system

2.3. Parameters calculation

Specific Activity

It was calculated for the radionuclides ^{226}Ra,^{232}Th and ^{40}K by the following relation [12];

$$A\ (t) = \frac{N}{\varepsilon \times I(E\gamma) \times m \times t} \times 100$$

Where N equals net area under peak, ε (E_γ) is the efficiency of energy E_γ detection. E_γ is the net peak area adjusted for the background at energy E_γ below the real peak. I(E_γ) is the abundance of E_γ energy. The sample mass in kg is m, andt the time in second.

Gamma absorbed dose rates

The calculation of the gamma absorbed dose rate by using the following equation [13, 14].

D_γ (nGy/h) = $0.462A_{Ra} + 0.621A_{Th} + 0.0417A_K$

Where the specific activities of ^{226}Ra, ^{232}Th, and ^{40}K are A_{Ra}, A_{Th} and A_K, respectively.

Annual effectiveDose equivalent

The annual effective dose equivalent (AEDE) from^{238}U (^{226}Ra), ^{232}Th, and ^{40}K is obtained by using the following equations [15]:

$AEDE_{out}(\mu sv/y) = D_{out} \times 8760 \times 0.7 \times 0.2 \times 10^{-3}$

$AEDE_{in}$ (µsv/y) $= D_{in} \times 8760 \times 0.7 \times 0.8 \times 10^{-3}$

Where, D is absorbed dose rate measured in nGy/h. The number of 0.2 refers to outdoor occupancy factor, 0.8 is indoor occupancy factor. The number of 0.7 Sv/Gy is conversion factor.

The Internal and External Hazard Index

The internal hazard index (H_{in}) and external hazard index (H_{ex}) due to the radiation released by the food samples is determined as follows[16, 17].

$$H_{ex} = \frac{A_{Ra}}{370} + \frac{A_{Th}}{259} + \frac{A_K}{4810}$$

$$H_{in} = \frac{A_{Ra}}{180} + \frac{A_{Th}}{259} + \frac{A_K}{4810}$$

Life-Time Cancer Risk

The excess lifetime cancer risk (ELCR) can be calculated fromthe following equation [18].

ELCR = AEDE× DL × RF

Where DL is duration of life (70 year) and RF is risk factor (0.05 Sv^{-1}).

Ingestion effective dose

The effective dose of ingestion due to the intake of ^{226}Ra, ^{232}Th and ^{40}K in food can be measured [19].

$E_{ing} = \Sigma (A_{ig} \times C_i) \times g_{T,r}$

where, A_{ig} and C_i the coefficients of the consumption rate and specific activity of the radionuclide, and $g_{T,r}$ is The radionuclide ingestion dose conversion coefficient, the required dose conversion coefficient $g_{T,r}$ for ^{40}K, ^{226}Ra(^{238}U), and ^{232}Th, are 6.2×10^{-9}, 2.8×10^{-7}, and 2.2×10^{-7} respectively [20].

3. Results and Discussion

The activity concentration was calculated in six samples of dried fruit and nine samples of grain of ^{238}U, ^{232}Th and ^{40}K as illustrated in Table 2. The average activity concentrations of^{40}K, ^{232}Th, and^{238}Uwere, 324.4±28.5 ,3.66±0.20, and 3.44±0.58Bq/Kg for dried fruit samples, 302.3±98.9, 4.8±1.5 and 4.29 ±1.4, Bq/kg for grain, respectively. The values were decrease than the world average values for ^{238}U, ^{232}Th, and ^{40}KUNSCEAR,2008 [21]. Turkey Figures and popcorn samples which have higher activity concentration, while the dried coconut and Iraq Millet samples have the lowest value. Figures 3 and 4 show the activity concentrations of ^{40}K, $^{238}U$and, ^{232}Th in samples of dried fruit and grain.

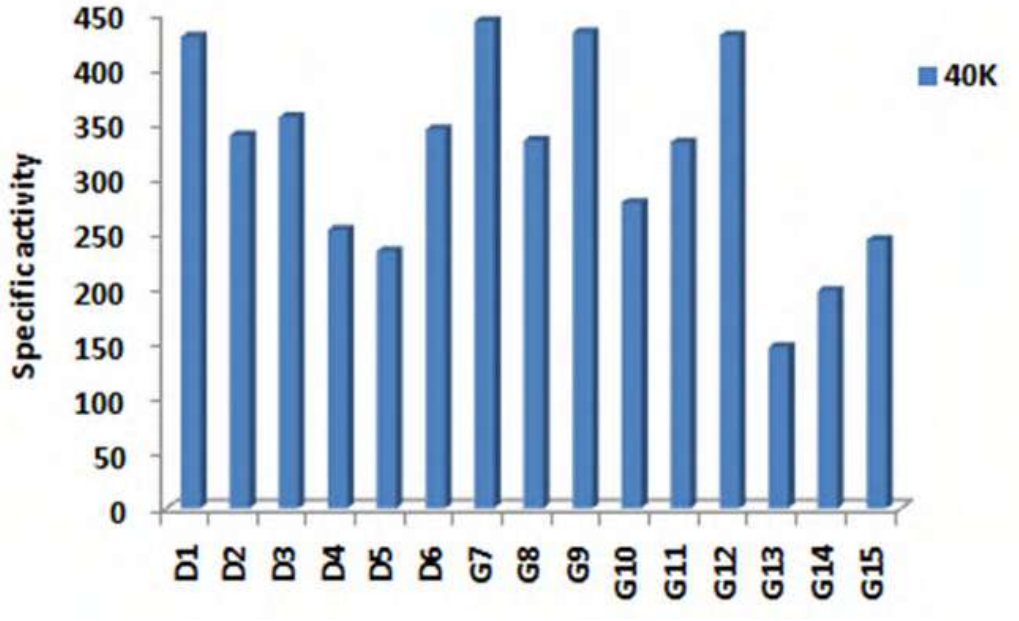

Figure3. The activity concentration of dried fruit and grain for 40K.

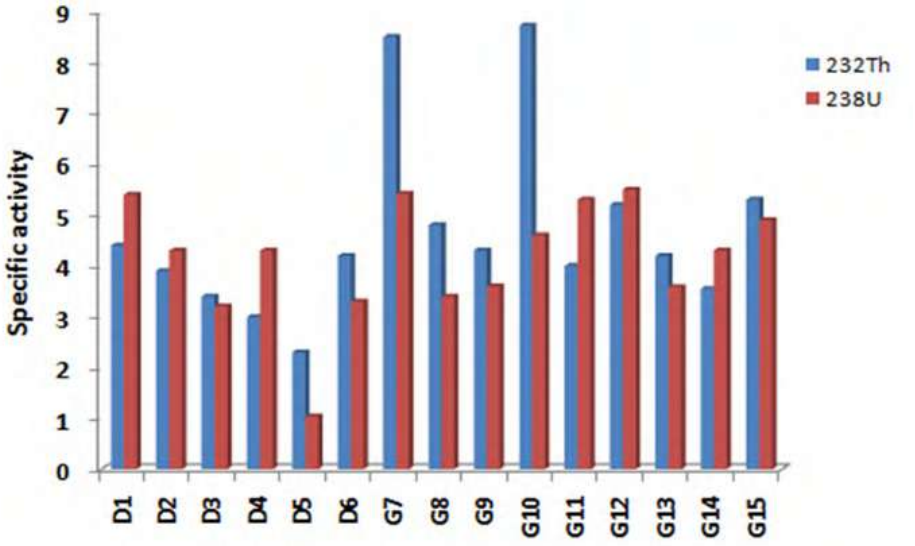

Fig.4. The activity concentration of samples for 238U and, 232Th.

Tables 3 show the results of radiation hazard index values outside and inside for the annual effective dose (ADED), outside and inside hazard (H_{ex},H_{in}), and lifetime cancer risk (ELCR). These values had been under the permissible limits (UNSCEAR, 2000)[22]. The radiation hazard index values inside the body were more than that outside the body due to the ingestion of nutrients and the rest of them within the body as shown as in Figure 3.

The highest life time cancer risk values in the figure and popcorn samples and the lowest value in dried coconut and millet samples as shown in Figure 5.

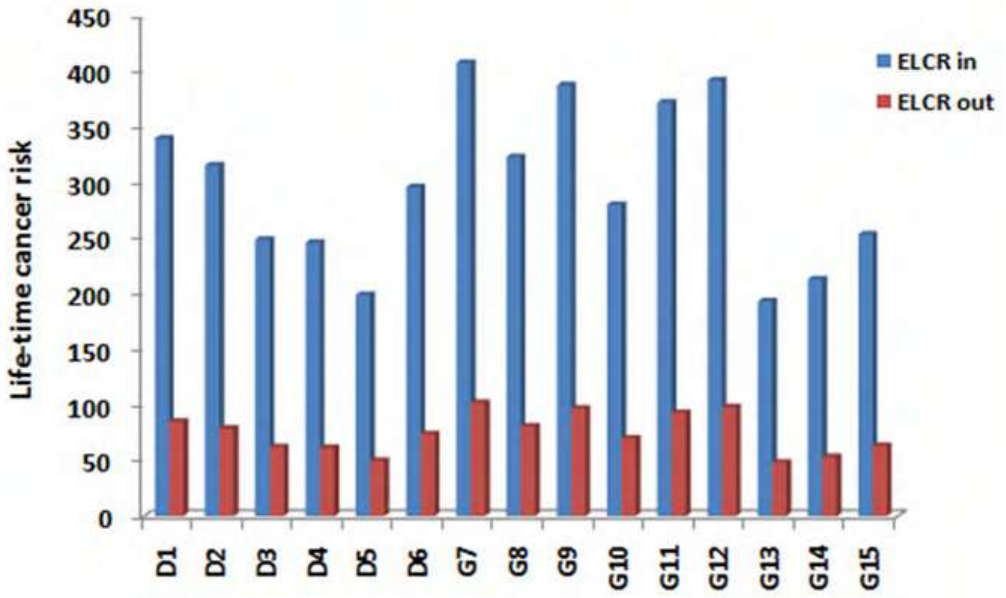

Figure 5. Life-time cancer risks of the samples.

For ^{238}U, ^{232}Th, and ^{40}K, the effective ingestion dose was lower than the acceptable dose ingestion effective dose values of 0.3 mSv/y recommended UNSCEAR, 2008 [21]. As shown in Table 4 and Figure 6, the effects of the effective dose ingestion in all samples are shown.

The average value of the dose ingested for ^{238}U, ^{232}Th and $^{40}K$was 0.009±0.001,0.010±0. 001and 0.02±0.01 for the dried fruit and 0.012±0.004,0.014±0.004 and 0. 023±0. 007 for grain.

4. Conclusion

Through calculations of the concentration of radioactivity for the ^{238}U, ^{232}Th, and ^{40}K for the samples and the radiation hazard associated with the ingestion effective dose for the dried fruit and grain, it was found that they do not contain high radioactivity that affects the human body. Indices of radiation risk that were assessed during the analysis for all samples inside the study, all samples within the international borders allowed, and it is necessary to conduct a deep study of the other types of foodstuffs to determine their suitability for human consumption.

Physical Characteristics for Biocomposite Material Using to Jawbones Compensation

Physical Characteristics for Biocomposite Material Using to Jawbones Compensation

Abstract. The biocomposite material prepared from polymeric blend (bone cement) as a matrix, and hydroxyapatite powder as a reinforcement material to jawbones compensation is a material that has a good compatibility in terms of physical properties with oral environment in general, and jawbones in particular. The physical properties such as density, water absorption, and thermal properties were tested according to the weight fraction for the reinforcement material. It was found that the density of biocomposite material does not uniformly changed, and it decreases with increasing the ratio of hydroxyapatite particles. While, the water absorption increases with increasing the weight fraction of hydroxyapatite particles. Also, the thermal properties were measured. It was found that the thermal conductivity and the thermal diffusivity of the prepared material were decreased with increasing the weight fraction of hydroxyapatite particles, and therefore the specific heat of the prepared material was also increased due to the porous nature for reinforcement material (hydroxyapatite powder) that enhances the formation of voids between the resulting material.

Keywords: Biocomposite materials, jawbones, density, water absorption, thermal conductivity, thermal diffusivity, specific heat.

1. Introduction

During the last few years, composite materials were widely used in medical applications [1,2] to compensate the damaged parts of the body such as bones, denture base, teeth implants, and dental fillings, etc. [3].

Generally, jawbones like other types of bones are a specialized type of connective tissue [4]. It consists of cortical and cancellous bone [5]. The biocomposite materials that used to compensate jawbone must have specific properties to be suitable for human's body especially for oral environment [6]. Biocomposite material for jawbone is a single composition with a uniform structure [7], and should satisfy many significant criteria as well as specific characteristics such as biocompatibility, osteoconductivity, corrosion resistance, strength, fatigue durability, and tight chemical similarity to biological apatite that exists in the human hard tissues [7,8]. Therefore, the preparation of any biocomposite material for jawbone compensation must have special biological, chemical, mechanical, and physical properties to be compatible with other body tissues [8,9].

In recent studies, the preparation of many biocomposite materials for compensating jawbones, biopolymer composite prepared from silicone rubbers were widely used for this purpose. Nanocomposites prepared from silicone rubbers as a matrix, and poly (methyl methacrylate) (PMMA)

as a reinforcement were succeeding for maxillofacial prosthesis and studied the effect of adding different percentage of nanopowder of PMMA on the physical properties [10]. The silicone rubber reinforced with hydroxyapatite powder (HAP) was used to compensate the damaged parts of the jaws [11]. The mechanical properties of biocomposite material were studied, and the PMMA was found to be a good biopolymer material to compensate human bones in general, and jawbones in specific [12]. PMMA as a denture base material was used, and it proved itself as success choice in this field due to its compatibility with oral environment and the mechanical and physical characteristics [13].
The objective of this work is to prepare a biocomposite material to repair the damaged parts of the jawbones and improves the performance of the jawbones using bone cement polymer reinforced with nanohydroxyapatite, and to study the physical properties of the prepared material.

2. Materials and Methods

2.1 Composition of Biocomposite Material

The biocomposite samples for jawbones compensation were prepared using (Hand lay-Up) method as a function of the specific weight ratios for all selected raw and reinforcement materials as shown in Table 1, and Table 2. Figure 1 shows the three types of reinforcement materials used in biocomposites.

Table 1. Materials used to prepare biocomposite material.

Materials	Symbol	Type	The use
Poly (methyl methacrylate)	PMMA	Powder	Matrix
Benzoyl peroxide	BPO	Powder	Matrix
Barium sulphate	$BaSO_4$	Powder	Matrix
Methyl methacrylate	MMA	Liquid	Matrix
N, N-Dimethyl para-toluidine	N, N-DMPT	Liquid	Matrix
Hydroxyapatite	HAP	Powder	Reinforcement

Table 2. Biocomposites materials and its chemical composition.

Materials	Powder			Liquid	
HAP wt.%	PMMA	BPO	$BaSO_4$	MMA	N, N-DMPT
0%	98				
1%	96.5				
2%	95				
3%	93.5				
4%	92				
5%	90.5	0.294	1.706	49	1
6%	89

10%	83				

Figure 1. The materials used as reinforcement in biocomposite materials: (a) Nanohydroxyapatite; (b) Hydroxyapatite prepared form fish bones; (c) Hydroxyapatite prepared form natural egg shells.

2.2 Preparation of Biocomposite Material

Biocomposite material for jawbones compensation was prepared according to the amounts mentioned in Table 2. The amount of all components was (2:1) powder per liquid. It is necessary to pour the powder into the liquid not the opposite and mix them in a glass bowl with a thin wooden stick. Three groups of biocomposite materials were prepared with (nanohydroxyapatite, hydroxyapatite prepared from fish bones, and hydroxyapatite prepared from natural egg shells) as reinforcement materials at different weight ratios of (0, 1, 2, 3, 4, 5, 6, 7, 8, 9 and 10)%.

By mixing the powder and the liquid, many changes will take place due to the solubility of a polymer in the monomer. The stages of mixing monomer and polymer acrylic materials include (sandy or granular, sticky, full dough, rubbery, and hard). The speed for the polymer and monomer mixture to reach the dough stage depends on the solubility of the polymer powder in the liquid monomer and increasing the temperature [14]. The components are mixed for 30 seconds and quickly poured into the molds cavities because the dough stage turned to hard stages quickly. A weight of approximately (2N) is putting above the prepared sample to obtain a smooth surface and to prevent the entry of gases vapor into the acrylic as well as the formation of bubbles during the curing process. In addition, the weight leads to coordinate the specimen molecules and the interference between them taking into account the lubrication of the mold of all directions to prevent the specimen adhesion. The prepared specimens are kept in the molds for 24 hours until the curing and polymerization processes for the acrylic specimens are completed. After the curing process was completed, the specimens were removed from the mold cavities with a very smooth upper and lower surface and polished with sandpaper to remove the small cracks resulted from the specimen's sides as a result of the specimen's adhesion with the mold cavity sides. All specimens were prepared and tested under the same conditions.

2.3 Physical Tests

The physical tests are carried out at room temperature 23±2˚C. All the tested specimens were stored in distilled water and heated at (37± 1℃) for 48 hours.

2.4 Density Test

Density or (Bulk density) is the mass per unit volume of a material. Specific gravity is a measure of the ratio of the mass of a given volume of material at (23°C) to the same volume of distilled water. The specific gravity and density can be calculated from equations (1), and (2), respectively [15]:

$$Specific\ Gravity\ (S.G.) = m_1/(m_1 + w - m_2) \quad (1)$$

$$Density\ (\rho) = (Specific\ Gravity)(S.G.) \times (0.9975) \quad (2)$$

where:

$S.G.$: Specific Gravity.

m_1: Mass of a specimen in the air (gm).

m_2: Mass of a specimen in the water (gm).

w: Mass of partially immersed wire.

ρ: Density (g/cm^3).

The density (g/cm^3) can be obtained by multiple specific gravities and the density of distilled water which is equal to (0.9975 g/cm^3) [15,16].
The specimens were prepared according to (ASTM D-792) standard [17], and the specimens weights were measured according to Archimedes method by examining the weight of the specimen in the air and then check the weight with water [18]. But, the volume should not be less than (1cm^3). This test was done by accurate balances PS 360/C/1device, as shown in Figure 2.

Figure 2. The density test device.

2.5 Water Absorption Test
Various polymeric materials are susceptible to water absorption during its life exposures which cause dimensional instability. Thus, subjecting the material to degradation internal stresses may result in crack formation, and eventually lead to fracture or failure of the jawbones [19]. The moisture content of a polymer is very intimately related to such properties as mechanical strength, appearance, and dimensions stability. The effect upon these properties is the change in water absorption that depends largely on the type of exposure to high humidity, the rigidity of 3-D structure, the thickness of the specimen, immersion time, temperature, type of solution, type of materials, bounding type, the geometry of the specimen, cross-linking, curing method, and inherent properties of the polymer [20]. The water absorption can be calculated according to the following equation:

$$Water\ absorption\ percentage = (W_s - W_d)/W_d \times 100 \quad (3)$$

where:
W_s: Mass of the specimen after immersion for (24 hours in distilled water).
W_d: Mass of the specimen before immersion (dry).
For the most parts, the polymer may suffer expansions and contractions when alternately soaked in water and dried. This parameter is important in clinical applications of the matrix resin since water uptake may affect the dimensional stability, physical, and mechanical properties of jawbones. The water absorption by acrylic jawbone is nearly independent of temperature from (0 - 60 ºC), and the thin specimens reach a steady-state within a short time [21].
The test of water absorption was performed according to (ASTM D570) [22]. The dimensions of the specimens are (L×W×H) (50 × 50 × 4) mm. Figure 3 illustrates the experimental specimens and standard dimensions of the specimen for the water absorption test.

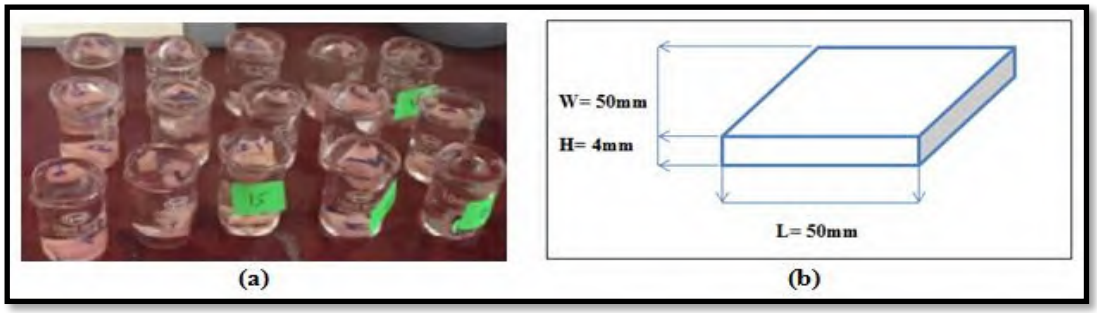

Figure 3. Water absorption test: (a) Experimental specimens; (b) Standard dimensions of the specimen for water absorption test.

2.6 Thermo-Physical Test

To evaluate the thermal properties of specimens, Hot Disk thermal analyses were used. The Transient Plane Source (TPS) technique was used to determine the (thermal conductivity, thermal diffusivity, and specific heat). The Hot Disk includes a heat source, and temperature probe as a flat sensor with a continuous double spiral of electrically conducting nickel (Ni) metal with a resistance of (11.56 Ω) to transform the thermal power which passes through the specimen to measure thermal transport properties, etched out of thin foil, sandwiched between two layers of insulating material. During the test, the sensor was normally placed between the surfaces of the two pieces of the specimen to be measured [23,24].

Measurements can be performed on many different materials; solids, liquids, powders, viscous materials, composites, etc. including various types of geometry, and dimensions. The Hot Disk (TPS) can also be used under various environmental conditions from very low temperature (-45°C) up to (1000°C) [25].

The relationship between the thermal properties is illustrated by [25,26]:

$$D_{th} = (K/C_p.\rho) \quad (4)$$

where:

D_{th}: Thermal diffusivity(mm^2/s).

K: Thermal conductivity$(W/m.K)$.

C_p: Specific heat at constant pressure$(MJ/m^3.K)$.

ρ: Mass density (Bulk density) (kg/m^3).

This test was performed according to the apparatus manual of standard specifications instrument [27]. The test was carried out by using the thermal properties test instrument, manufactured by (Kelthley), type (Transient Plane Source (TPS) - 500). Figure 4 (a) illustrates the instrument used for the thermo-physical properties test. This apparatus was used for investigating the thermal transmission properties, such as thermal diffusivity (C_v) or (D_{th}), volumetric specific heat (C_p), and thermal conductivity (K) which were determined by utilizing the Hot Disk sensor. A hot disk sensor was placed between the two pieces of the same specimen material prepared at the same dimensions of the standard specifications instrument, which are a least as thick as the radius of the sensor, functioning mechanical support, and electrical insulation as shown in Figure 4 (b), and then heated by an electrical current for a short period of time [28]. The lavished heat generates a temperature rise of both the sensor and the surrounding specimen material. To avoid the influence from the outside boundaries of the specimen, the specimen should be larger than the sensor diameter to ensure stable values of both thermal diffusivity, and conductivity. The values of thermal diffusivity, thermal conductivity, and specific heat were taken from the computerized gauges.

3. Results and Discussion

3.1 Density Property

From important measurements, the density of biocomposite material is the basic indicator for knowing the lighter prepared biocomposite materials [15]. Generally, the biocomposite materials have a lighter weight than biometals or bioceramic. This is one of the main reasons why using biocomposite materials in vivo applications [29].

The density of biocomposite specimens in this study is measured according to the Archimedes method using an equation (2). Figure 5 illustrates the relationship between the density, and the weight fraction of the reinforcing particles (HAP powder), which were added to the polymeric matrix (bone cement). It can be seen from the curve that the density values for biocomposite specimens increase with increasing weight fraction of HAP powder to the mixture (polymeric matrix) because the density of HAP particles is higher than that of PMMA [30,31].

Generally, prepared specimens had different densities, where the density for specimens has not constant change in proportion with the weight fraction of the reinforcement material (HAP powder) because other influential factors such as no homogeneity through the preparation process may affect the density of the specimen.

Pure PMMA has a density equals to (1.2 g/cm^3) [31], and MMA has a density equal to (0.93 g/cm^3) [32]. Other components of the matrix also have specific densities, while the density of the reinforcement (HAP powder) is (2.62 g/cm^3) [30]. The density for prepared specimens was between (1.32-1.91) g/cm^3, and the lower density was found at (2%) of (n-HAP) and (3%) of (HAP prepared from egg shells and fish bones). The higher density was found at (9%) of (n-HAP) and (10%) for (HAP prepared from egg shells and fish bones), respectively. These results differ from the results in reference [13] due to the difference in the reinforcement material, while it is in good agreement with the results in reference [10].

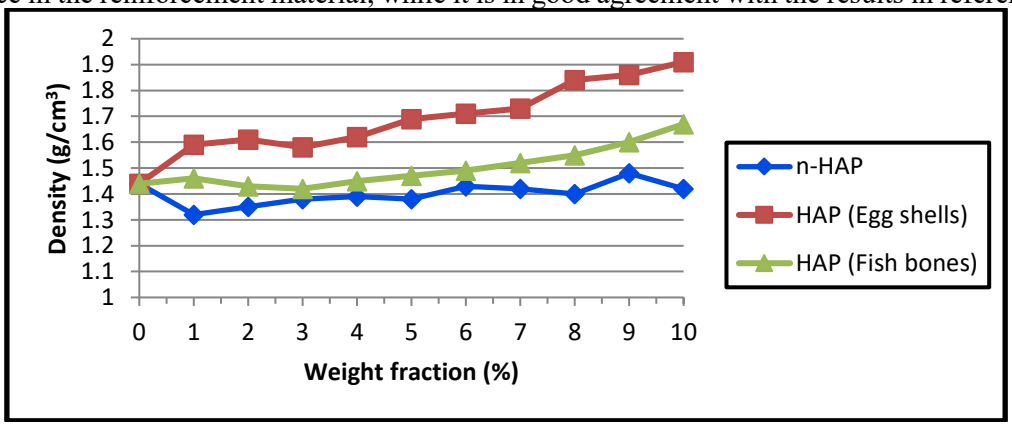

Figure 5. Density as a function of weight fraction of the reinforcement particles (HAP powder) in biocomposite material.

3.2 Water Absorption Property

The relationship between the water absorption of biocomposite material and reinforcement material HAP particles is illustrated in Figure 6. The water absorption values of the polymeric matrix and biocomposite material with HAP particles for all specimens that fabricated in this work are illustrated in figure 6. It can be observed from the figure that the water absorption decreases with increasing the weight fractions of HAP particles. This is due to the attitude of the particles towards the moisture, and also may be due to the porosity nature of HAP particles. Therefore, the water absorption is very little. In previous study, HAP particles were used as reinforced material with silicone rubber as a matrix, and the water absorption was not found [11]. Also, PMMA powder was used as a matrix with (bamboo, and siwak) fibers as a reinforcement, and it found that the water absorption increases with increasing the weight fraction of fibers and fiber's length [10].

In general, biocomposite specimens with HAP powder graded of absorption for water-dependent on the weight fraction of reinforcement, as well as the specimens with lower density have higher water absorption. The density decreases with increasing the moisture absorption [33]. Polymeric matrix (bone cement) specimen without reinforced material have a high value of water absorption equal to (1.443%), while biocomposite specimens with HAP particles have a low value reaches (1.1%) for a specimen with weight fraction (10%). This increase in water absorption is interpreted as a result for the existence of a bioceramic material (HAP) in the prepared biocomposite material, and these results are identical to the results in reference [34].

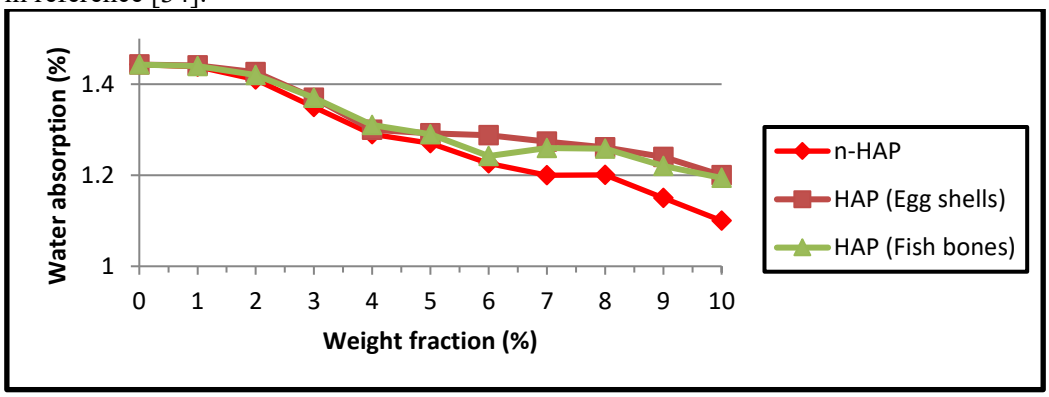

Figure 6. Water absorption as a function of weight fraction of the reinforcement particles (HAP powder) in biocomposite material**.**

3.3 Thermo-Physical Properties

The thermal-physical properties (thermal conductivity, thermal diffusivity, and specific heat capacity) are properties obtained from the hot disk test for biocomposite specimens at room temperature. The relationship between these properties is given by equation (4) which illustrates decreasing the thermal conductivity and improving the specific heat to decrease the thermal diffusivity of specimens [35].

Thermal Conductivity Results: Thermal conductivity for biocomposite material represents the thermal energy that causes movement of the molecular chains of polymer in biocomposite specimens at a rate proportional to the weight fraction of the conductive materials [36]. Thermal conductivity results are illustrated in Figure 7.

This figure illustrates that when increasing the weight fraction of HAP particles, the thermal conductivity of the biocomposite specimens decreases. This is due to the role of HAP particles that have thermal conductivity lower than that for PMMA matrix. Also, the presence of bioceramic HAP particles of a porous structure and conglomerate of biocomposite specimen as a result of increasing the weight fracture from HAP powder that lead to the difficult process of heat transfer through the composite specimens, and can considerably poor thermal conductivity. This is made better molds for the characterization of bone cement thermal behavior [37].

Figure 7 illustrates the polymeric matrix (pure) has a higher thermal conductivity value equal to (0.1622 W/m.K), while the biocomposite specimens have lower values than the polymeric matrix. The maximum values of thermal conductivity for biocomposite specimens with (n-HAP, HAP prepared from egg shells and HAP prepared from fish bones) particles at the optimum condition of weight fraction (1%) equal to (0.1604 W/m.K), (0.1525 W/m.K) and (0.1551 W/m.K), respectively, and have minimum values at (10%) (0.0918 W/m.K), (0.0645 W/m.K) and (0.0775 W/m.K) respectively. The biocomposite specimens with less weight fraction of HAP have higher thermal conductivity value than biocomposite specimens with high rates.

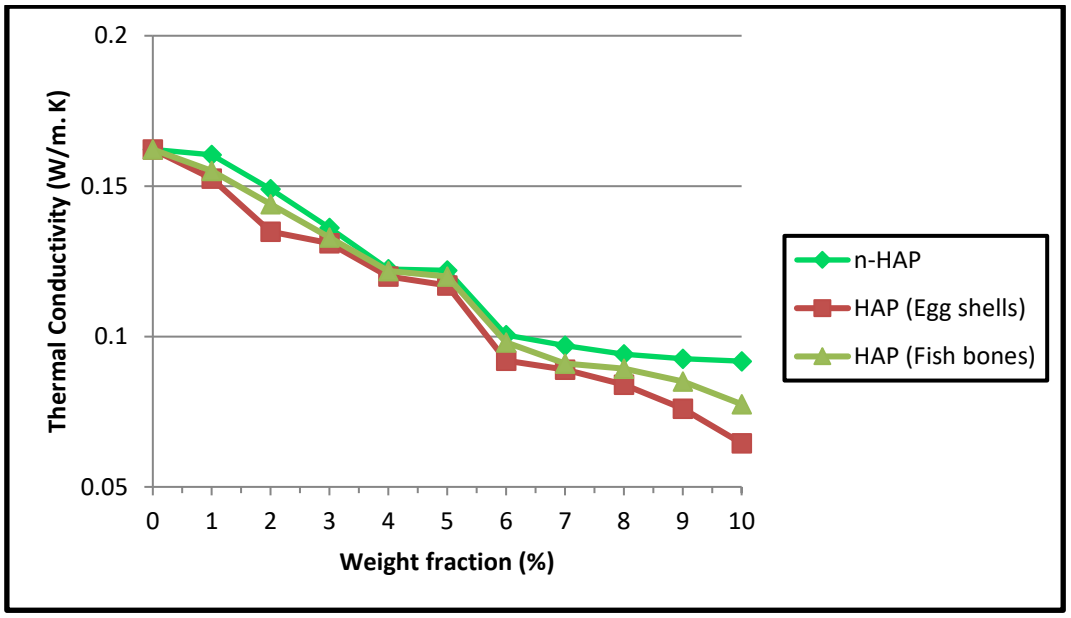

Figure 7. Thermal conductivity as a function of the weight fraction of the reinforcement particles (HAP powder) in biocomposite material.

Thermal Diffusivity Results: The thermal diffusivity of specimens indicates the change in the composite specimen's temperature in the test when the heating is applied [38].
Figure 8 shows the relationship between the thermal diffusivity and the weight fraction of the reinforcing HAP particles added to the matrix (bone cement). The thermal diffusivity of the composite specimen decreased with increasing the weight fraction of (n-HAP) reinforcing particles added to the matrix (bone cement). The pure matrix (bone cement) has a higher value of thermal diffusivity than the composite specimen reaches (0.06182 mm^2/s). So, the higher values of biocomposite specimens reinforced by weight fraction equal (1%) reach (0.0602 mm^2/s, 0.0515 mm^2/s and 0.0549 mm^2/s) for composite specimens having (n-HAP, HAP prepared from egg shells and HAP prepared from fish bones) particles, respectively. While, composite specimens have thermal diffusivity decreased with increasing weight fraction of HAP particles. These results differ from those obtained for composite specimens PMMA reinforced with fibers (bamboo and siwak) which show that the thermal diffusivity of specimens is increased with increasing the weight fraction and the fiber length of (bamboo and siwak). In addition, siwak specimens have higher values of thermal diffusivity than bamboo specimens [10].

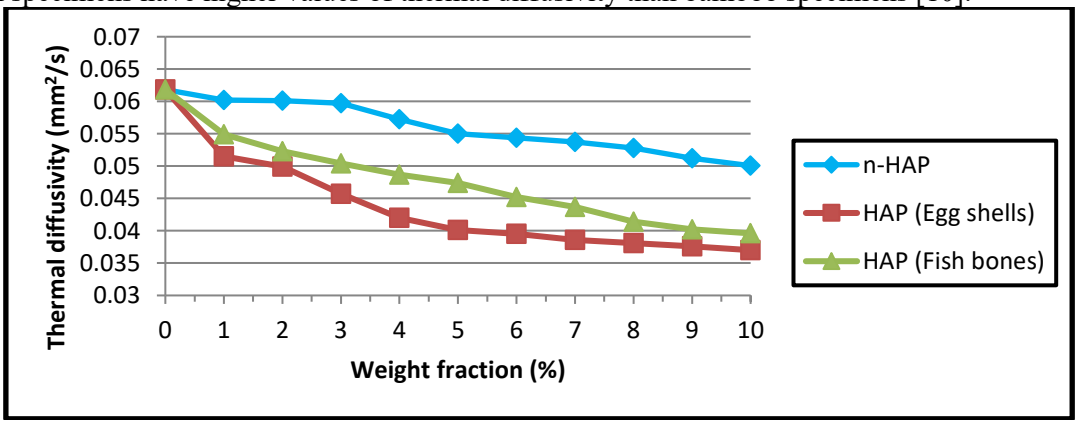

Figure 8. Thermal diffusivity as a function of the weight fraction of the reinforcement particles (HAP powder) in biocomposite material.

Specific Heat Results: The specific heat for biocomposite specimens represents the energy required to raise the temperature T_g of biocomposite specimens by one degree [36].
Figure 9 illustrates the relationship between the specific heat, and the weight fraction of the reinforcing particles (HAP powder) added to a pure matrix (bone cement).
Specific heat magnitudes could be increased by increasing the weight fraction of HAP particles compared with the magnitude of PMMA alone. Therefore, the highest values of specific heat for biocomposite specimens are obtained for biocomposite with (10%) weight fraction of HAP particles. This could be attributed to the formation of spaces and voids between the particles because of the porous nature for HAP particles, which consequently led to an increase in specific heat.
The pure matrix (bone cement) has lower value than biocomposite specimens with reinforcing HAP powder that equal to (2.319 MJ/m^3.K).
The highest values of specific heat were found with biocomposite specimens at (9%) weight fraction of (n-HAP) particles, and (10%) of (HAP prepared from egg shells and HAP prepared from fish bones), that reach to (3.246 MJ/m^3.K), (3.59 MJ/m^3.K), and (3.36 MJ/m^3.K), respectively. This is different from composite specimens with (bamboo & siwak fibers) that have a lower value of specific heat than pure PMMA [10].

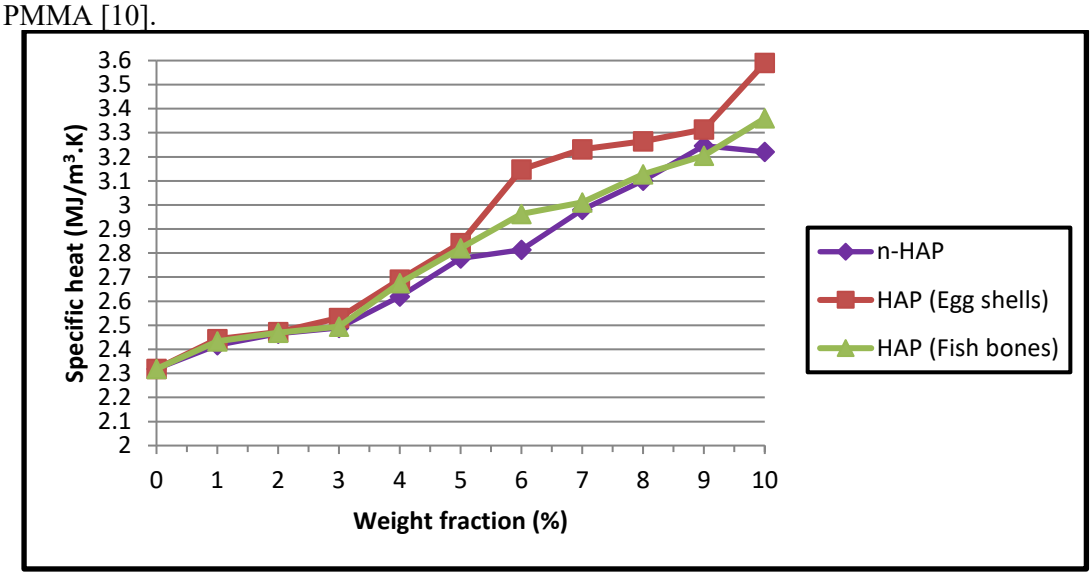

Figure 9. Specific heat as a function of the weight fraction of the reinforcement particles (HAP powder) in biocomposite material.

4. Conclusions

The experimental physical tests used for the biocomposite materials prepared in this study led to the following conclusions:
The biocomposite material prepared from biopolymer (bone cement) as a matrix and reinforced by bioceramic (HAP powder) as filler is a material with good compatibility, as the physical properties of the prepared material are suitable with the jawbone material in particular, and with the body in general.
The prepared biocomposite materials have different densities, where the density for prepared specimens lay between (1.32-1.91) g/cm^3. Therefore, the density of these samples increases with the weight fraction of HAP powder.
The rate of water absorption of biocomposite specimens with HAP particles is grading dependent on the weight fraction of reinforcement, where polymeric matrix (pure) specimen without reinforcement have

the higher value of water absorption, while biocomposite specimens with HAP particles have lower values, and decreases with increasing the weight fraction of HAP powder.
The maximum values of thermal conductivity and diffusivity of the biocomposite specimens are at a weight fraction less than the HAP powder, and the minimum values of them at the weight fraction higher than it.
Specific heat is inversely proportional to both thermal conductivity and diffusivity, so, it increases with increasing the weight fraction of the reinforcement material.

E-mail: Ghzlan82sn@gmail.com

Abstract. In this work, InSe thin films were deposited on glass substrates by thermal evaporation technique with a deposit rate of (2.5∓0.2) nm/sec. The thickness of the films was around (300∓10) nm, and the thin films were annealed at (100, 200 and 300) ˚C. The structural, morphology, and optical properties of Indium selenide thin films were studied using X-ray diffraction, Scanning Electron Microscope and UV–Visible spectrometry respectively. X-ray diffraction analyses showed that the as deposited thin films have amorphous structures. At annealing temperature of 100 ˚C and 200 ˚C, the films show enhanced crystalline nature, but at 300 °C the film shows a polycrystalline structure with Rhombohedral phase with crystallites size of 17.459 nm. The results of the UV–Visible spectrometry in the wavelength range (300 – 1100) nm showed that the band gap energy of the thin films increased with increasing annealing temperature.

Keywords: InSe, Thin Film, annealing, Optical, structural, Vacuum Thermal Evaporation

1. Introduction

Numerous studies have been focused on Indium monoselenide (InSe) as a semiconducting layered compound since it exhibits a good photoelectric property and can be used as an active media for the generation of visible and near-infrared radiation[1]. InSe thin films are used as high energy radiation detectors owing to its high stability towards ionizing radiation [2]. Also, it used as solar cells due to its optical energy gap between (1 and 2) eV 3]. The problem of the preparation of high quality thin InSe films is still unsolved due to the existence of several In–Se phases [4]. Therefore, it is considered of complicated stoichiometries due to the existence of InSe, In_2Se_3, In_4Se_5, In_4Se_3, and In_6Se_7 phases [5]. Moreover, (InSe) exhibits at least three modified crystalline phases of (2H-β) (two-layer hexagonal, 2H) and (2H- ɣ) or (3R-δ) (three-layer rhombohedral, 3R) [6,7]. There are five relatively known phases of In_2Se_3 compound α (hexagonal), β (rhombohedral), ɣ (hexagonal), δ, as well as the recently discovered k phase (anisotropic structure)[7,8]. Indium selenide has two crystalline surfaces showing very different physical properties. The cleaving surface perpendicular to the z-axis consists of Se atom bounded together with covalent bonds. The other surface parallel to the z-axis is made up of Se atoms of adjacent layers being bounded by Van der Waal forces [8,9]. Depending on the deposition technique and deposition conditions, one of the crystalline forms of InSe is produced. Each form has a unique range

of structural, optical and electronic properties [10] and thin-film growth method on substrates [11].So far, many techniques are used to prepare InSe thin films such as chemical bath deposition [12], Spray pyrolysis [13], sol gel method [14] and thermal evaporation[15].
In this work, we firstly prepared InSe alloy at (In:Sn = 50%:50%), and the InSn thin films were thermally evaporated on glass substrates. The structural, Topographical and optical properties of Indium Selenide thin films were studied as a function of different annealing temperatures.

2. Experimental

In this work, InSe compound was prepared from Indium (99.99% purity) and selenium (99.99% purity) elements mixed into a sealed and evacuated quartz tube at (5×10^{-2} mbar), and then the quartz tube was heated at 900 °C for 1 h in a furnace followed by ice water quenching. The tube was broken to extract the substance that was grinded to be used for depositing the thin films using thermal evaporation technique under a vacuum of (3×10^{-5}mbar). Glass substrates were cleaned by detergent with ethanol and rinsed ultrasonically in deionized water. The glass slides are placed on a shaped semi ball-holder inside the thermal evaporation chamber, and the InSe compound was evaporated using Mo boat. The Indium Selenide thin films were evaporated at room temperature onto cleaned glass substrates. The thickness of the films was determined by using weighing method to be (300 ∓ 10) nm, and the thin films were annealed at (100, 200 and 300) °C.
(XRD) patterns were obtained using a (SHIMADZU Japan -XRD600) with a CuKα source of λ=1.54059 Å to study the crystal structure of the thin films. (VEGA3-TESCAN model, USA) scanning electron microscope (SEM) was used to study the surface morphology. (UV-visible 1800 spectra photometer) in the wavelength range (300 – 1100) nm was used to study the optical properties of thin films.

3. Results and Discussion

3.1. The XRD diffraction analysis

Fig. (1) shows the XRD diffraction analysis of the InSe alloy. This result indicates the appearance of InSe, In_2Se_3 in different phases. In addition, the highest peak of (006) plane is related to the Rhombohedral structure of InSe. A few weak peaks with mixed indices indicating that in addition to the trend along c- axis (0012) and (0018), there are also some other crystalline features along (110), (116) and (119). By comparing the results with the standard cards for ICDD 's of different (InSe, In2Se3, In_4Se_3, In_4Se_5, In_6Se_7…) structures, we observe the emergence of different peaks corresponding to the phases (InSe-M, InSe-R, InSe-H). Also, some peaks have compatible Miller indices, for example (116) and (114) related to the phases InSe-R and InSe-H, respectively. The peaks with incompatible Miller indices, such as (201) and (103) are related to the Monoclinic and Rhombohedral phases respectively. This is because the Rhombohedral is a special case of hexagonal structure. Similarly is applied to the In_2Se_3 structure, and Table (1) shows XRD results for the alloy.

The XRD patterns for the as-deposited and annealed InSe thin films with 300 nm show that the as-deposited thin films are amorphous in nature. After annealing at 100°C and 200°C, the films show enhanced crystalline nature, and the film annealed at 300°C shows a polycrystalline structure. These results are in good agreement with those in reference [15].The transformation to polycrystalline structure is due to the recrystallization process during the annealing of the thin film. Annealing process led to the cancellation of some levels presented after the growth and rearrangement of the crystalline grains within

the lattice after taking a sufficient energy to grow and arrange [16]. This result indicates the appearance of InSe- Rhombohedral phases with the orientations of (006), (101), (104), (110), (116) and (021). The preferred orientation was along (101) R plane. The spectrum also contains two weak peaks correspond to the Se- Monoclinic phases. Table (2) Shows XRD results for InSe thin films annealed at 300 °C.

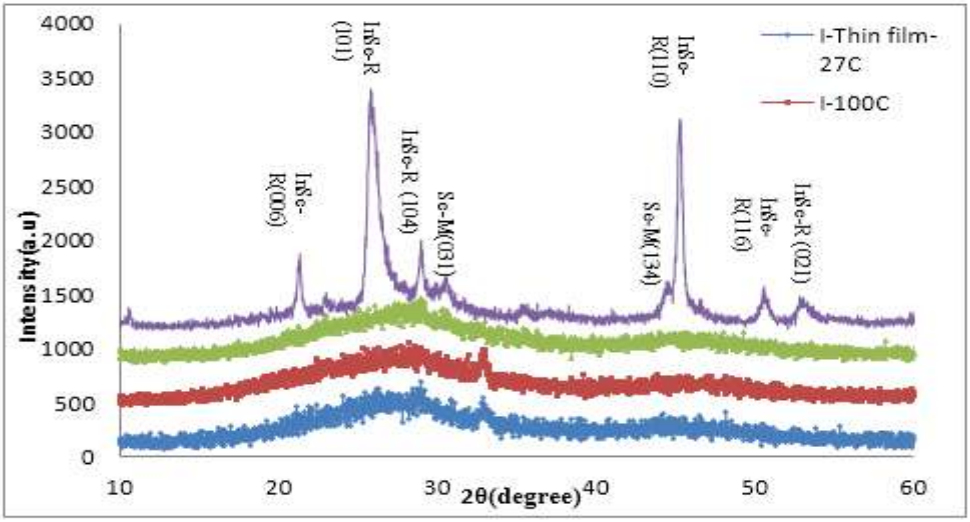

Figure 2. X-ray diffraction analysis of thin film: R means rhombohedral of InSe thin films; M means Monoclinic of Se

Table 2. XRD results for thin film annealed at 300 °C.

JCPDScard No.	Phase	2θabsor	2θstand.	d-abs	d-stand.	hkl
00-042-0919	InSe-R	21.35	21.353	4.15	4.1583	006

	InSe-R	45.29	45.281	2	2	110
	InSe-R	50.60	50. 581	1.802	1.8	116
	InSe-R	53.08	52.918	1.72	1.728	021

The crystallite size was estimated from the (β) value of the preferential orientation along (101)R plane using the Scherrer relation [17]:

$$C.s = k * \frac{\lambda}{\beta * \mathrm{Cos}\theta} \qquad (1)$$

where C.s is the crystallite size, k ≈ 0.9, λ is the wavelength of X – ray radiation, θ is the Bragg's angle of the(101) peak in degrees, and β is the peak width of the diffraction peak profile at half maximum. The calculated crystallite size of the thin films was found to be 10.157 nm.
The dislocation density (δ) was estimated from relation (2) [18].

$$\delta = \frac{1}{C.S^2} \qquad (2)$$

The micro strain (ε) is one of the important factors in lattice dynamics calculated from relation (3) [19].

$$\varepsilon = \beta * \frac{\cos\theta}{4} \quad (3)$$

The number of crystallites per unit surface area (N_o) was calculated using relation (4) [20].

$$N_0 = \frac{t}{C.S^3} \quad (4)$$

where t is the thickness of the thin film

The calculated Crystallite size, dislocation density, micro strain and the number of crystallites per unit surface area for the preferred orientation along (101)R plane of InSe thin film annealed at 300 ºC were listed in Table 3.

Table 3. Crystallite size, dislocation density ,micro strain and the number of crystallites per unit surface area for InSe thin film annealed at 300 ºC.

2Θ (degree)	hkl	β(deg)	β (rad)	C.s(nm)	δ $(nm)^{-2}$	ε	N_o $(nm)^{-2}$
26	101	0.839	0.0146	10.157	0.0097	0.0035	0.286

Due to the convergent change in the structural properties of the annealed films at temperatures of (100 and 200) ºC, we will ignore the morphology and optical properties of the film annealed at 200ºC.

3.2 Morphology

Scanning electron microscope (SEM) was used to study the thin film surfaces. Morphological information of these thin films is shown in figures (3, 4 and 5).

The as deposited film shows a particle size of (50nm). While the films annealed at 100 ºC and 300 ºC show particle sizes of (300nm) and (280nm) respectively.

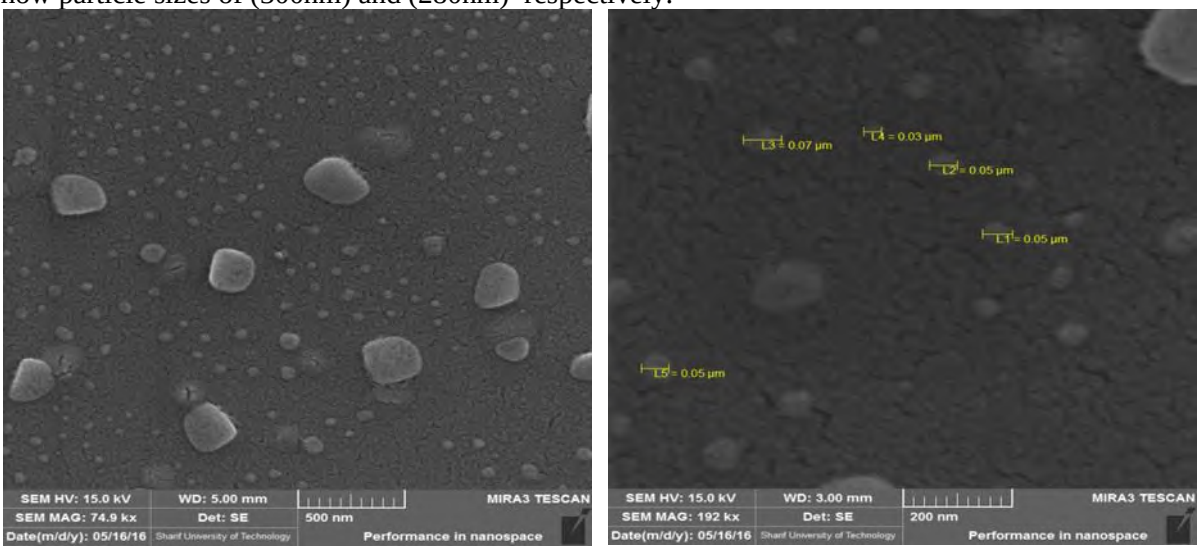

Figure 3. SEM images of as deposited InSe thin film at different resolution.

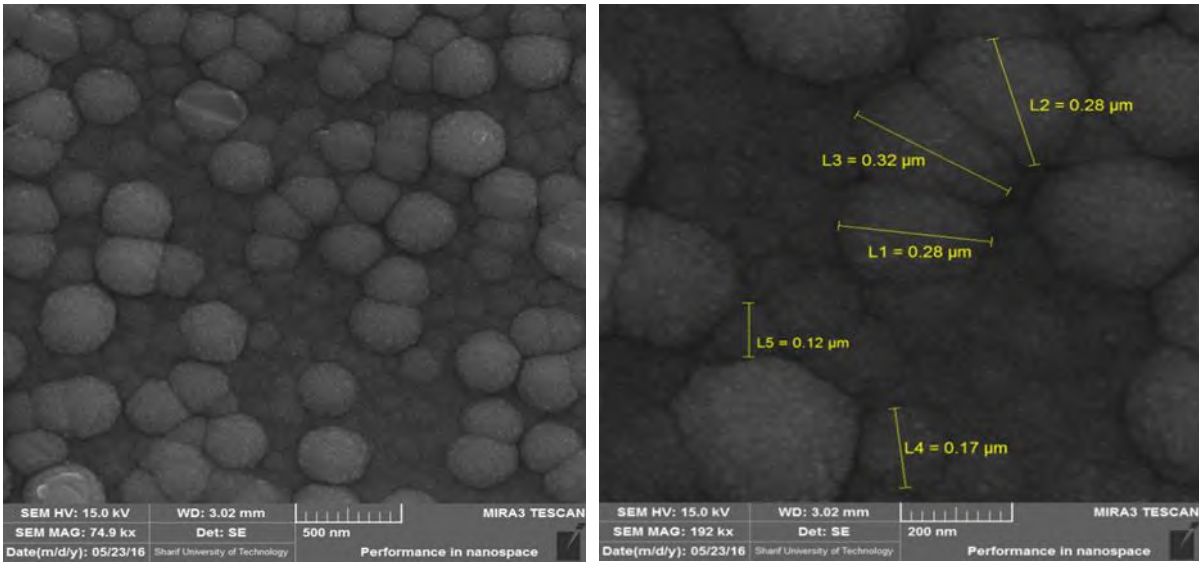

Figure 4. SEM images of annealed InSe thin film at 100 °C and at different resolution

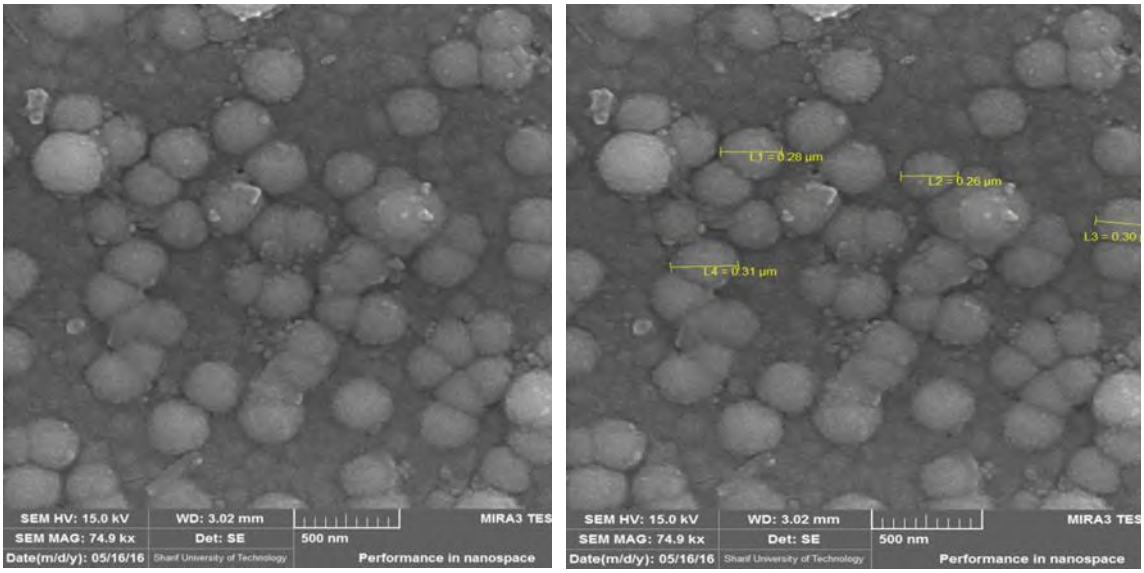

Figure 5. SEM images of annealed InSe thin film at 300 °C and at different resolution

3.3 Optical Properties

The absorbance spectra of as deposited and annealed (InSe) thin films are shown in figure (6). It is observed that the maximum absorption at a wavelength range of (300 -700) nm is suitable for the solar cell applications in this region.

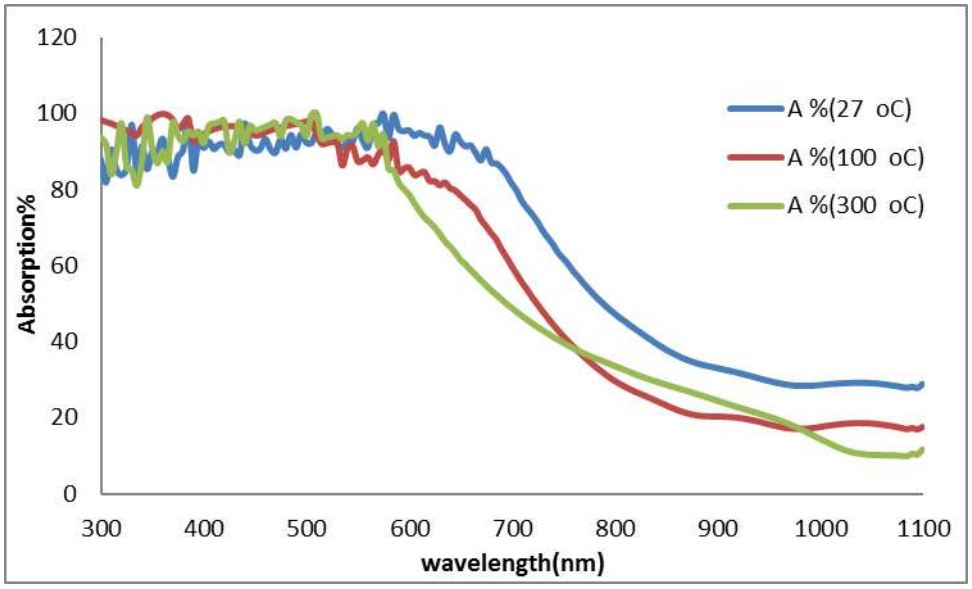

Figure 6. Absorption of InSe thin films as a function of annealing temperature: at (as-prepared, 100 and 300)ºC.

Figure (7) shows the transmittance spectra of InSe thin films at different annealing temperature. We noticed that the maximum transmittance at a wavelength range of (1000 -1100) nm at (as-prepared, 100 and 300)ºC. The annealing temperature plays an important role in the transmission spectrum by increasing transmission. On the other hand, the film annealed at 300 ºC shows improved transmission compared to that annealed at 100 ºC. This tuning of transmission by annealing indicates their utility as various technological applications. The film deposited with higher annealing temperatures shows a higher transmittance. These results agreed well with [16].

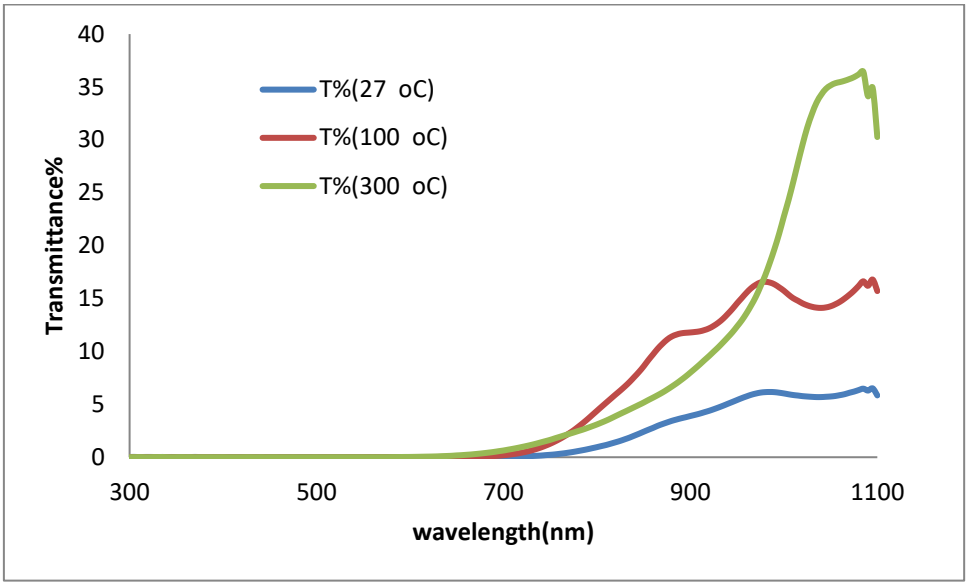

Figure 7. The transmittance of InSe thin films as a function annealing temperature: at (as- prepared ,100 and 300)°C.

The absorption coefficient (α) behaves as absorption behavior, and (α) was determined by equation 5) [21]:

$$\alpha = 2.303\frac{A}{t} \quad (5)$$

A is the absorption

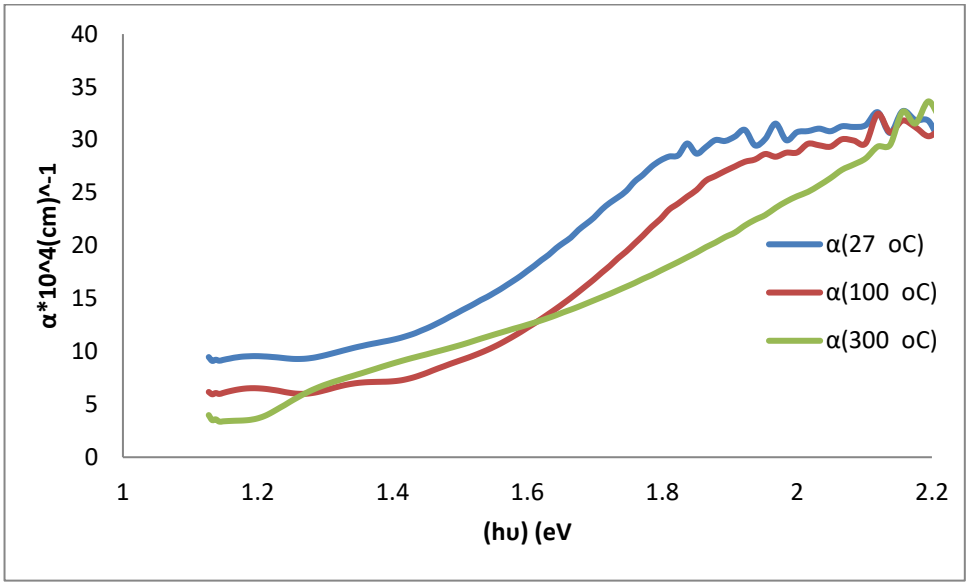

Figure 8. The variation of the absorption coefficient with energy for InSe thin films as a function of annealing temperature: (as-prepared, 100 and 300) °C.

The extinction coefficient (K) of InSe thin films were determined by equation (6) [22,23].

$$k = \frac{\alpha\lambda}{4\pi} \quad \text{.....(6)}$$

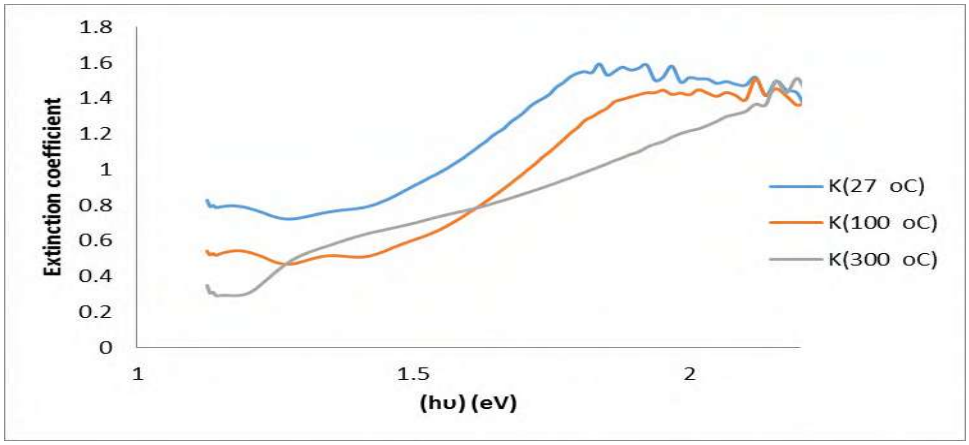

Figure 9. Extinction coefficient Vs Wavelength of InSe thin films: as a function of annealing temperature at (as-prepared, 100 and 300) °C

The optical band gap was calculated by Tauc's extrapolation method [24].

$$\alpha h\nu = B(h\nu - Eg)^r \quad (7)$$

where : (h) Planck's constant, (ν) frequency of the photon, (B) Constant and r is constant depends on the nature of transitions, r =1/2, 3/2, 2 and 3 for direct allowed, direct forbidden, indirect allowed and indirect forbidden respectively.

Compared to the plot of $(\alpha\ h\nu)^2$ variation with hν for the determination of direct band gap Eg which is shown in Figure 10. The optical band gap values are showed in Table 4.

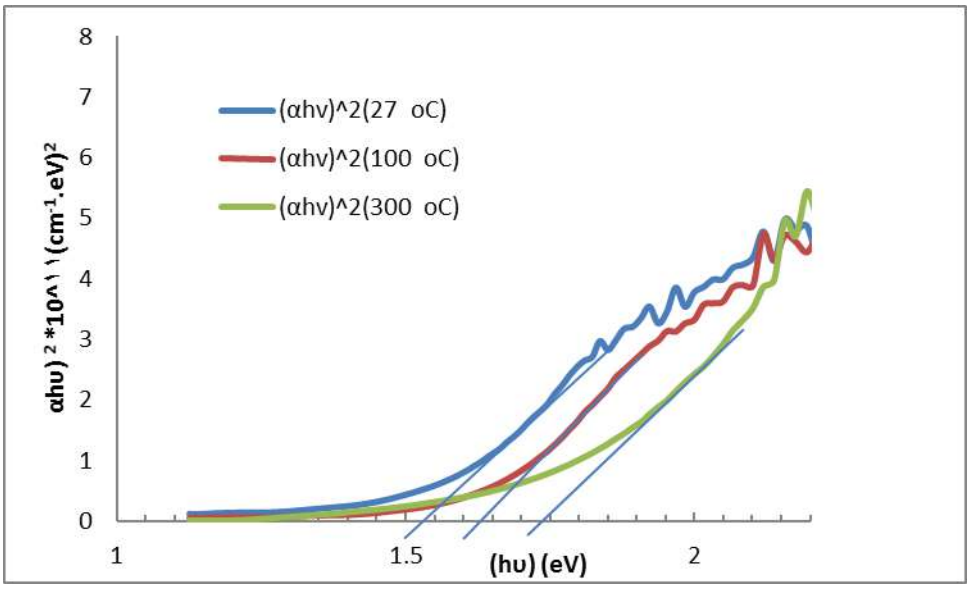

Figure 10. Plot of $(\alpha h\upsilon)^2$ versus (hυ) for InSe thin films as a function of annealing temperature (as-prepared, 100 and 300) °C

The band gap energy increases with increasing annealed temperature. The optical band gap values changes from 1.55 to 1.75 eV. The value of E_g is in good agreement with the reported values (1 – 2 eV) for InSe films. Table.4 shows the values of band gap energy for annealed InSe thin films.

The reduction in the number of unsaturated defects decreases the density of localized states in the band structure, consequently increasing the band gap [25].

Table 4. Bandgap variation of InSe with different annealing temperatures.

Temp. °C	Eg(eV)
as-prepared (27)	1.55
100	1.65
300	1.75

4. Conclusion

$In_{50}Se_{50}$ bulk samples are prepared by melt quenching technique and thin films of powdered alloys are deposited using thermal evaporation technique. The XRD pattern revealed that the as deposited films are amorphous in nature and annealed at 300˚C films exhibit polycrystalline nature. It was found that the physical properties of the films are heavily affected by annealing temperature. The absorption

edge and optical band gap depended on the crystalline structure. This tuning of transmission and band gap on annealing temperature indicates their utility in various technological applications.

Abstract. Proton beam therapy provides favorable physical characteristics to kill cancer cells. It is known that all living organisms contain DNA, so we will simulate the bombardment of dry DNA of human's body cells by protons. The knowledge of stopping powers is very important especially for ion beam cancer therapy. The simulations first-principles dynamics helps the mostly employed linear description of response theory. The study denotes that DNA has suffered ionization by proton bombarding, which leads to long –lasting harm to human or cancer DNA that empowers us to diagnose the latter and treat it with radiation. Through using Bethe and Ziegler's equations, and also the SRIM programs, we determine the stopping power of the interaction of proton with human's DNA at approximate energy of 1 to 2.5 MeV. The human's DNA components are made of five main elements. All mathematical processes and analysis are achieved using Matlab program. The results are introduced in tables and figures. The researchers have formulated the power equation that denotes the values of stopping power according to the range of energy under investigation.

Keywords: Bethe equation, Ziegler equation, energy loss, Human cancer DNA, Stopping Power, SRIM.

1. Introduction

The particle therapy has introduced new innovative therapy for cancer by giving developed precision and radiobiological characteristics over the common photons. Globally, there are more than 150,000 patients treated in the present time [1]. Interaction between incident protons and human biological materials is highly significant to expect the influences of radiation on the live tissues and radiation dosimetry. The use of beams with energetic ion of radiation therapy becomes an encouraging method since more doses can be placed topically on the tumor spots to decrease the destruction of the contiguous crucial body parts. Hadron-therapy use of the energy deposition at the point that the penetrating proton beams will lose whole energy, i.e. the swift decreasing for the dosage at this point that could be employed for high dose deposition inside a particular swelling size. Electrons and photons do not have this property [2]. In radiotherapy of cancer, the choosing of the range and energy of the incident protons are vital for dose control. There is an extensive development in numerous algorithms employed to determine the dose depth and allocations for ion beams. Applying of Bethe theory on the solids where energy loss of particles measurements depends on it shows us the term energy loss is important for mean excitation energy of the material[3].

Charged particles can pass through matter and ionize the atoms they come across. They will lose their energy steadily numerous tiny stages. Mostly, they employ the mass stopping power that refers to the linear stopping power divided by density to express by units like MeV/(mg/cm^2). Then, it is manifested as the loss of energy for each unit of the attenuator thickness measured in g/cm^2[4]. So, it can be considered that there is an independence of the stopping power with respect to the density of the material. We can consider stopping power as crucial issue in several areas of technology, particularly high-tech usage in addition to medical procedures [5]. The paper investigates the energy loss by electronic excitations of the beams of fast proton through DNA for discrete and continuum states at varied incident energy.

The rapid charged particle, which passes through a medium, loses its power mainly by electronic excitation of object particles excluding the situation at very low speeds [6]. Incident particles may lead to main DNA destruction by physical and chemical interventions within a short period of time. So, the elastic energy loss will be ignored within the energy limit measured. It should be observed that in the range of low and medium energies, we need to regard the electron capture procedures and incident particle losses that provides an unceasing charge interchange of the projectile in their pathway through the solid influencing its energy loss. The loss of energy happens when protons crossing matter by succeeding collisions with the particles and atoms that they encounter. It is worth noting here that loss of energy is mainly because proton collisions by electrons in stopping material [7].

If protons encounter an extremely light nucleus, they will scatter, recoil nucleus could move to a substantial extent before the energy is entirely precipitated [8].Since the dose of radiation precipitated by photons decrease progressively with pervasive depth, the deposited dose by protons rises gradually to almost up to three-quarters of its travel distance inside stopping material, then increased to reach extreme value before swiftly slow to zero. Bragg peak is the depth that the extreme energy is deposited by protons. The position of the peak is relational to the proton beam energy [9].

2. Bethe Equations

The particles beam that crosses a target will lose its energy. The loss of energy is because of scattered electrons and nuclei, and the stopping electronic is clearly manifested almost in all regions of energy. The loss of energy relies on energy or more accurately the beam velocity. A quantum-mechanical derivation comprises relativistic effects identified as the Bethe - Bloch equation [10]:

$$\mathrm{S.P} = \left(\frac{ze^2}{4\pi\varepsilon_0}\right)^2 \frac{4\pi Z\rho N_A}{Amv^2}\left[\ln\left(\frac{2mv^2}{I}\right) - \ln(1-\beta^2) - \beta^2\right] \quad (1)$$

where: S.P stopping power, $v = \beta c$ is the ion velocity, ze = ion charge, m = mass of electron, I = ionization potential, N_A =Avogadro's number, A, Z, ρ were the numbers of mass, atomic number, and density of the stopping material, respectively [10].

3. Ziegler Equations

Varelas and Biersack suggested a theoretical interpolation to treat the gap between maximum and minimum energy for various states by chief terms [11]:

$$(\mathrm{S.P_{DNA}})^{-1} = (S_{LOW})^{-1} + (S_{HIGH})^{-1} \quad (2)$$

S_{LOW} represent the low energy stopping and equal to:

$$S.P_{LOW} = A_1 E^{1/2} \quad (3)$$

S_{HIGH} represents the high energy stopping and equal to:

$$S.P_{HIGH} = \frac{A_2}{E}\ln\left(1 + \frac{A_3}{E} + EA_4\right) \quad (4)$$

A_1,A_2,A_3 and A_4 are fitting constants in able (1).

Table 1. Fitting constants for equations (3 and 4) [11].

Elements	A_1	A_2	A_3	A_4
H	1.44	242.6	1.2	0.1159
O	3	1920	2000	0.0223
N	3.35	1683	1900	0.02513
C	2.989	1445	957.2	0.02819
P	3.647	3561	1560	0.01267

In situation of high incident energy, fitting formula equation (2) approximately corresponds to equation (1). Therefore, the formula of Varelas and Biersack has a greatly plainer and the valid approximate conduct at all energy ranges [11].

4. SRIM software

Measurements of "Stopping and Range of Ions in Matter" can be made by software like SRIM. There are many scientific references to SRIM annually. Current SRIM has new improvements depending on new empirical data. The latest version contains major improvements based on experimental data [12, 13].

5. Results and discussions

The entire stopping power of protons interacts with the DNA elements that measured employing the three methods as follows; Bethe equation, Ziegler equation and the computer program SRIM software.

Considering the human DNA as composed of five elements which are hydrogen 30%, oxygen 16%, nitrogen10%, carbon40%, and Phosphorus 4%.

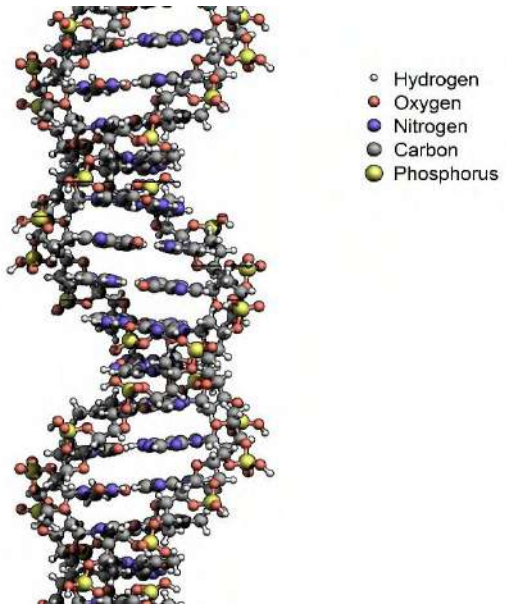

Figure1. DNA strands [14]

The total stopping power of proton interaction with H, O, N, C and P for energy range from 1 to 2.5MeV are measured employing the abbreviated formula of equation (1) [10].

$$S.P_{DNA}=0.239114\frac{Z_p}{E_p} ln\left[2.178 \times 10^{-3}\frac{E_p}{I}\right] \quad (5)$$

The measures are achieved by Matlab, with reliance on the values of the ionization potential for the elements as I_C=1.0039e-4 eV, I_H= 6.8560e-005 eV, I_N= 1.0895e-004 eV, I_O= 1.1769e-004 eV, I_P= 1.8155e-004eV.

Also we can use equations (2-4) to measure the total stopping power by Ziegler equations. And then we use the SRIM program to obtain the stopping power to the mentioned elements separately. All data are presented in figures (2-*6*).

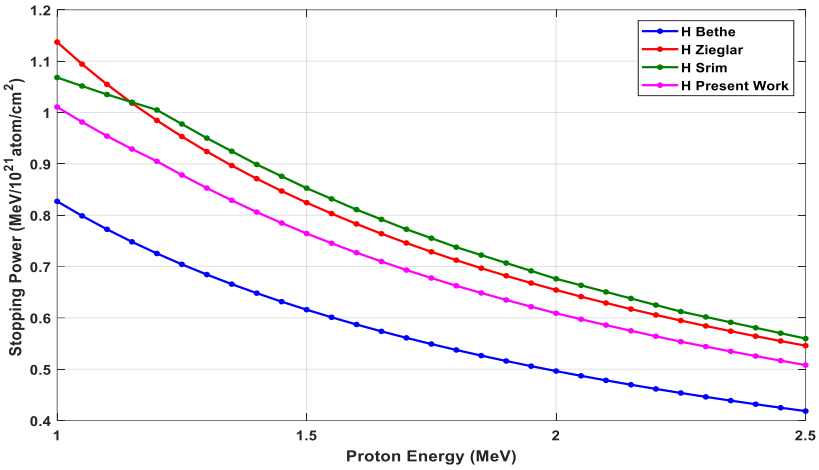

Figure 2. Proton stopping power in hydrogen

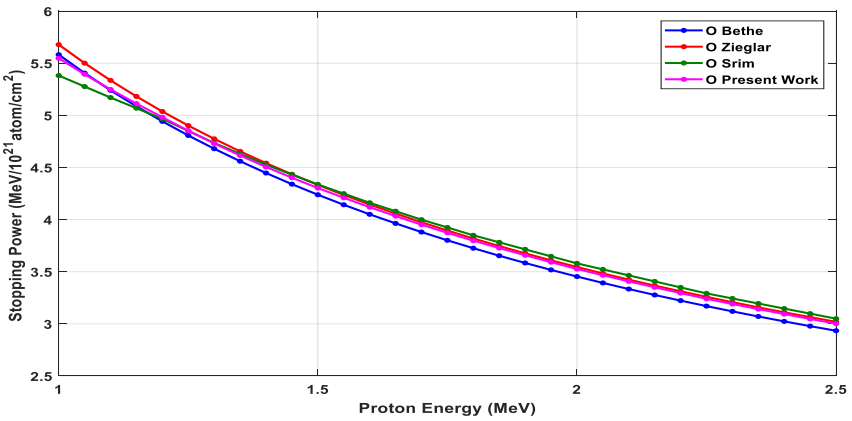

Figure 3. Proton stopping power in Oxygen

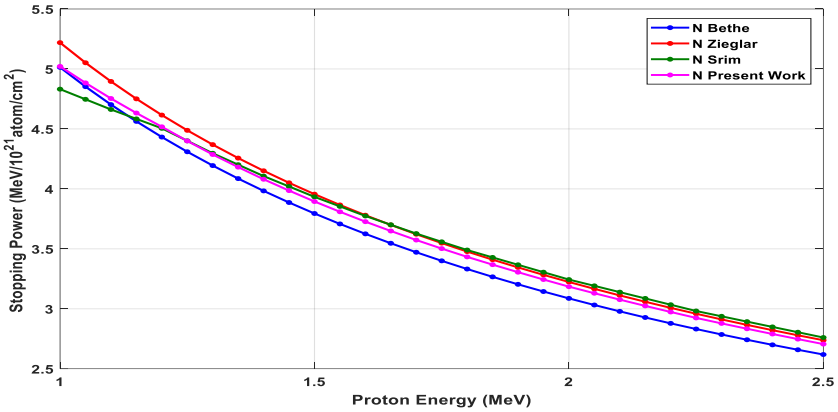

Figure 4. Proton stopping power in nitrogen

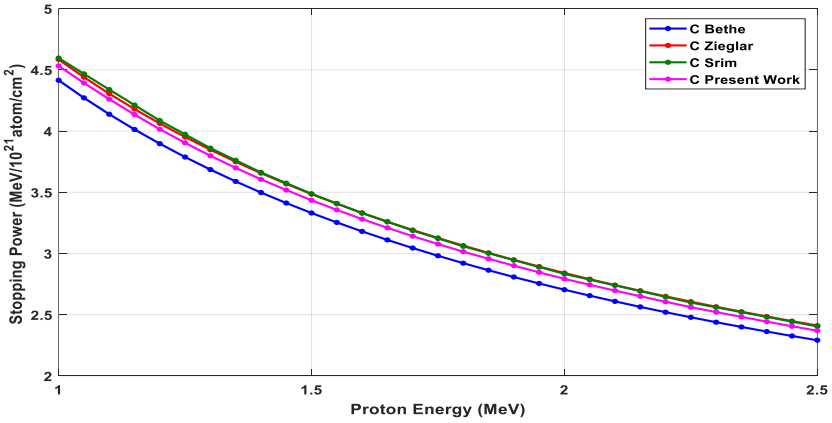

Figure 5. Proton stopping power in carbon

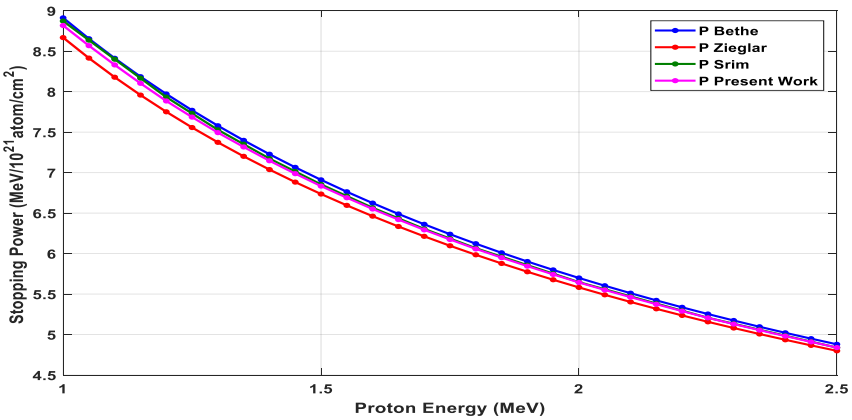

Figure 6. Proton stopping power in phosphorus.

So, using Bragg additively, the stopping power for human DNA was calculated by equation (*6*) and extrapolated to extract equation (*7*) to use in a wide range of protons energy.

$$S.P_{DNA} = 0.3\,S.P_{H} + 0.16\,S.P_{O} + 0.1\,S.P_{N} + 0.4\,S.P_{C} + 0.04\,S.P_{P} \quad (6)$$

General model Power equation:

$$S.P_{DNA} = a \times (E_p)^{b+c} \quad (7)$$

Coefficients (with 95% confidence bounds):

a = 4.919
b = -0.5071
c = -1.05

The results are shown in figure (7) and table (2).

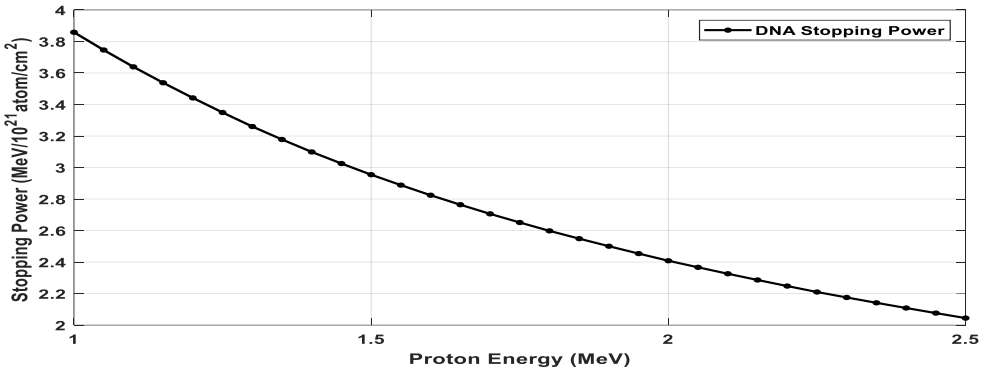

Figure 7. Proton stopping power in the DNA of human cells.

Table 2. Proton stopping power in the DNA of human cells.

Ep MeV	DNA Stopping Power
1.0000	3.8584
1.3000	3.2602
1.5000	2.9544
1.7000	2.7059
1.9000	2.5005
2.0000	2.4083
2.1000	2.3259
2.3000	2.1753
2.5000	2.0444

Conclusion

The crucial objective is the DNA for the most of biologic radiation impacts that includes the killing of living cells, cancer-making and mutation. Incident ionizing protons may prompt DNA destruction by the interaction of major and minor particles (direct) and also by the interaction of radiolysis yields with the DNA target (indirect) for a specific Short time range.

Three methods have been validated to calculate the stopping power of protons in DNA main components. After that, the algebraic process of the stopping power for specific component was taken in order to reduce the simple discrepancies in it, followed by the total stopping power of the DNA was calculated taking into consideration the percentages of participation of each element in the formation of DNA, Then the results were fitted to obtain a general equation to obtain the stopping power of the DNA in all proton energy ranges.

The Ziegler and SRIM were the true representation of Bethe equation by our six curves.

Our results for stopping protons in the DNA aim to provide an extra accurate description of the biological milieu.

Our expectations correspond with the existing empirical data and theoretical measures existed in the literature of the most of proton energy range studied here (*I*MeV –2.5MeV), however, there were huge variances perceived at lower energies.

Study of Some Structural and Optical Properties for P3HT: CBM Heterojunctions Blending of ZnS Nanoparticles

Study of Some Structural and Optical Properties for P3HT: CBM Heterojunctions Blending of ZnS Nanoparticles

Ghaida Salman Muhammed

Department of physics, College of science, University of Baghdad, Baghdad, Iraq.

E-mail: ghaidasalman7@gmail.com

Abstract. In this work, the preparation of P3HT: PCBM heterojunction blending ZnS nanoparticles (NPs) was demonstrated. Some structural and optical properties of the hybrid structure films were presented. ZnS NPs films were prepared by chemical route method and at different pH values. Then, the nanoparticles ZnS was incorporated in P3HT: PCBM solution in chlorobenzene with the weight ratios of 0, 5, 10 and 15 wt %. The X-ray diffraction patterns of the ZnS nanoparticles films and SEM images of the hybrid structure films are discussed. Also, the absorption spectra in the range of 200-1100 nm of the blends for variable weight ratios samples and the effect of ZnS pH values on these spectra are presented.

Keywords: nanostructure, organic materials, conjugated polymer, P3HT: PCBM, chemical rate method, x-ray diffraction, optical properties.

1. Introduction:

Organic materials are safe materials with unlimited availability which are used to develop the technology with active economy for extensive power generation. The organic semiconductors are cheap materials in comparable with the inorganic semiconductors. Also, the optical absorption coefficients of these materials are high which offer the prospect for the manufacture of thin film solar cells [1, 2]. Hybrid solar cells often use an incorporating of nanostructured materials as a network of electron-donor and electron-acceptor materials. These solar cells using the blending of materials are to convert sunlight into electricity [3]. P3HT polymers have been proposed to manufacture polymer : fullerene solar cells because they can absorb visible light and their glass transition temperature ≅110C° [4]. The morphology and the mobility of pure P3HT and blended P3HT: PCBM films are highly dependent on casting conditions [5, 6]. In the photoactive light absorbing thin film, a conjugated polymer is consider as organic part and a semiconducting nanocrystals (NCs) as an inorganic part [3].

In the present work, P3HT and C60 derivative PCBM material with the blending ZnS nanoparticles (NPs) on polymer-fullerene matrix are used. The inorganic semiconductor ZnS was used as the n-type material and the P3HT: PCBM as the photoactive layer. In this study, we concentrated on the effect of the concentration of ZnS on P3HT: PCBM photoactive layer and for three pH values. Hence, these materials combination has been used to study the light absorption characteristics.

2. Experiments:

P3HT: PCBM: ZnS NPs layers were prepared by spin coating as a precursor solution on pre-cleaned glass substrates. The glass substrates were first ultrasonicated in distilled water, ethanol, and subsequently dried in oven. The P3HT: PCBM layer was constructed by spin-coating method with 1:1 weight ratio solution in chlorobenzene at the glass substrate. Then, the ZnS nanoparticles were incorporated in P3HT: PCBM solution in chlorobenzene with the weight ratios of 0, 5, 10 and 15 wt %. Also, the ZnS NPs were prepared by the chemical route method. The ZnS NPs were prepared by mixing two chemical solutions. The first solution was prepared by dissolving 1.3g of ($ZnCl_2$) in 100 ml distilled water. Sodium hydroxide was used to reach the pH of the solution to the required amount of (pH=8.5, 9.5 and 10.5). The second solution was obtained by dissolving 0.7g from (Na_2S) in 100 ml distilled water [4]. Because of the common ion effect, the pH controlled the rate of reaction. With a spin-coating speed of 1000 rpm for 30s, P3HT: PCBM: ZnS NPs solution was deposited at the glass substrate. The annealing temperature was at 120 °C for 10 min. The ratios of P3HT: PCBM: ZnS NPs were (1:1:0, 1:1:0.05, 1:1:0.01 and 1:1:0.15), respectively. The film thickness of P3HT: PCBM: ZnS NPs was about 120 nm. The area of the sample was estimated to be (2.5x2.5) cm^2.

The structural properties of the films were investigated by using X-ray diffraction pattern (XRD). The surface morphology of the films was tested by using a field emission scanning electron microscope (FE-SEM, S-4200, and Hitachi) operated at 15 kV.

Also, the absorption spectra of the films were measured at room temperature using a SHIMADZU UV-1800 UV-VIS spectrophotometer. The spectrophotometer range is from (200- 1200) nm.

3. Results and Discussion:

3.1 X-Ray Diffraction:

XRD of ZnS (NPs) films are illustrated in Figure 1. Three prominent broad peaks are presented for all samples. The values of 2θ for these peaks are located around of 28°, 47° and 56° corresponding to (111), (220) and (311) diffraction planes respectively. This result indicates to the cubic structure for the prepared nanocrystals. Also, 2θ peaks located around 31°, 34°, 36°, 62° and 67 are related to (100), (002), (101), (013) and (112) planes respectively, which indicate to the hexagonal wurzite structure of polycrystalline ZnO. This result reveals the partial and complete oxidation of ZnS NPs in various mediums. In addition, the broadening of the peaks reveals to the formation of small size of ZnS nanocrystals [7, 8].

The prepared samples of pH (8.5, 9.5 &10.5) have average crystallite size of (11.5, 14.3 &12) nm respectively. The increasing of the intensity of ZnS NPs (111) peak indicates to the increasing of the crystallinity which is due to the increasing of the pH value of the samples. This result is comparable with result of other researchers [8].

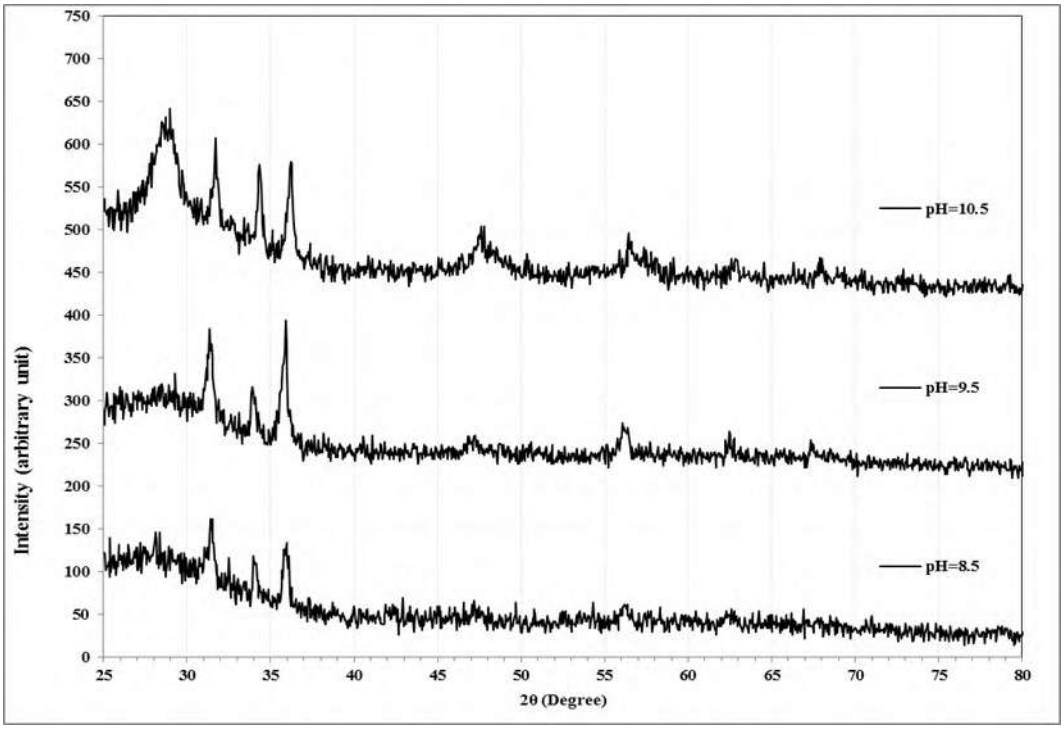

Figure 1. The XRD patterns of the ZnS nanoparticles prepared by chemical route method.

3.2 Scanning Electron Microscope Analysis (SEM):

Figure 2 shows the SEM images of ZnS NPs film, P3HT: PCBM film and P3HT: PCBM blending ZnS NPs hybrid film. The SEM study of the ZnS NPs film is shown in Figure 2a. The distributions of ZnS NPs are of irregular shape in the entire region with an average diameter of ZnS NPs about 85 nm. Figure (2b) shows the SEM image of P3HT: PCBM film. It can be noticed from this figure the uniform distribution of the film. To study the distribution of ZnS NPs in this layer, the microstructures of the P3HT: PCBM blending ZnS NPs hybrid film by SEM was used, as shown in Figure 2c. It was found that the distribution of the ZnS NPs is irregular distribution and the average diameter was about 57 nm. It is estimated that the decreasing of surface energy is attributed from the assemble effect results from nanoparticles [9].

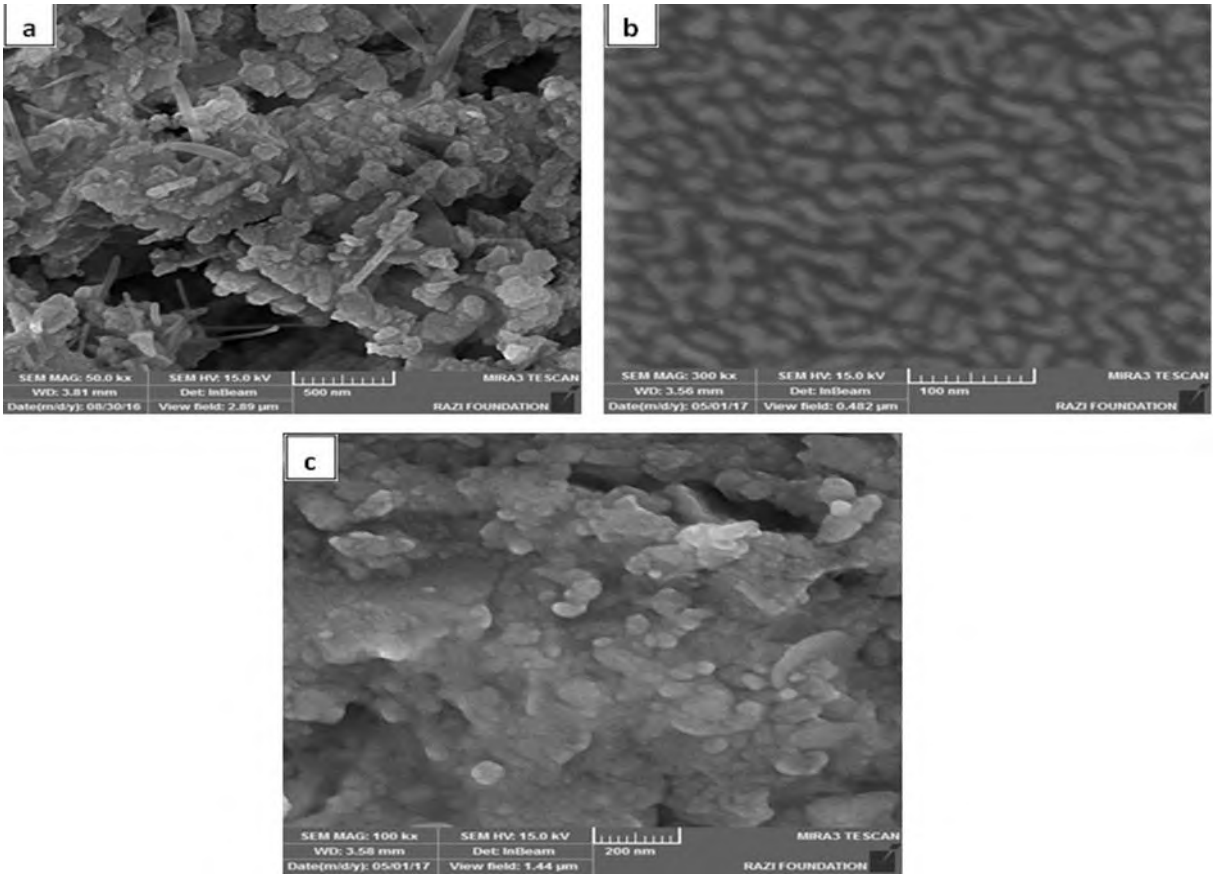

Figure 2. The SEM images of (a) ZnS nanoparticles, (b) P3HT: PCBM film and(c) P3HT: PCBM: ZnS NPs hybrid film.

3.3 Optical Properties Study:

The absorption spectra of the blends and for variable weight ratios samples of ZnS NPs are illustrated in Figure 3. The broad absorption peaks from 400 nm to 650 nm is resulted from the $\boldsymbol{\pi}$-$\boldsymbol{\pi}$* transitions. Absorption spectra of the blends shown in this figure are simply reveals to the combination of nanoparticles and polymer without any further absorption peaks [10, 11] because there is no any ground state interaction between them [12]. The little stretching of absorption edge of the P3HT: PCBM: ZnS NPs to the lower wavelength region is resulted from the quantum confinement effect from the inorganic nanoparticles. Also, the blue shift is due to the rising in band gap between π and π* energy levels. The insertion of the nanoparticles decreases the inter- chain interaction and conjugation length of P3HT.

Also, the addition of ZnS NPs into the P3HT: PCBM matrix increased the crystallization of the P3HT and captures more incoming light, therefore the magnitude of the absorption is increased [13]. It can be noticed, that the increasing of the ZnS NPs ratio leads to decreasing the absorbance, and this is because of the aggregation of ZnS NPs martial which can increase the recombination of exitons. Due to the high amount of the light absorption intensity, the generation rate of excitons is improving [9].

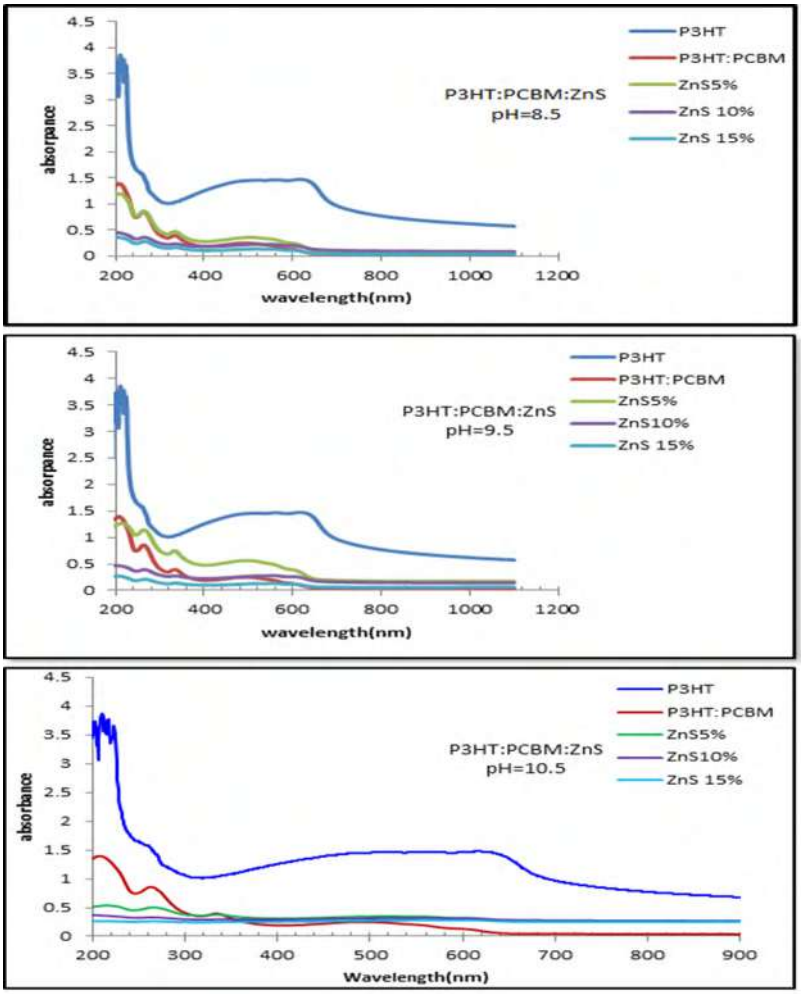

Figure 3. Optical absorption spectra of P3HT, P3HT: PCBM and P3HT: PCBM: ZnS NPs hybrid films for different pH values and concentrations of ZnS nanoparticles.

Also, the previous figure shows that the spectrum has two bands, one in UV region which is called B-band (or soret) band in the range about (240-350) nm due to the direct transition between the bonding π in HOMO and the anti-bonding π* in LUMO for all samples, and the other band is in the visible region which is called Q-band, and it consists of two close peaks in the range of 530-750 nm.

Figure 4 illustrates the relation between $(\alpha h\upsilon)^2$ and the photon energy ($h\upsilon$). The optical energy gap values (Eg_{opt}) for P3HT: PCBM and P3HT: PCBM: ZnS films with different pH values have been calculated using Tauc equation [11]. This figure reveals that the values of direct optical energy gap, increases by adding ZnS nanoparticles and for the lower concentration of 5% and for different pH is attributed to the increase of absorbance intensity in the visible region. Whereas, it decreases for other ZnS loading (10% & 15%) and for different pH values due to the decreasing of the absorbance in the visible region. Table 1 illustrates optical constants for P3HT: PCBM:ZnS films for different pH and concentrations of ZnS nanoparticles.

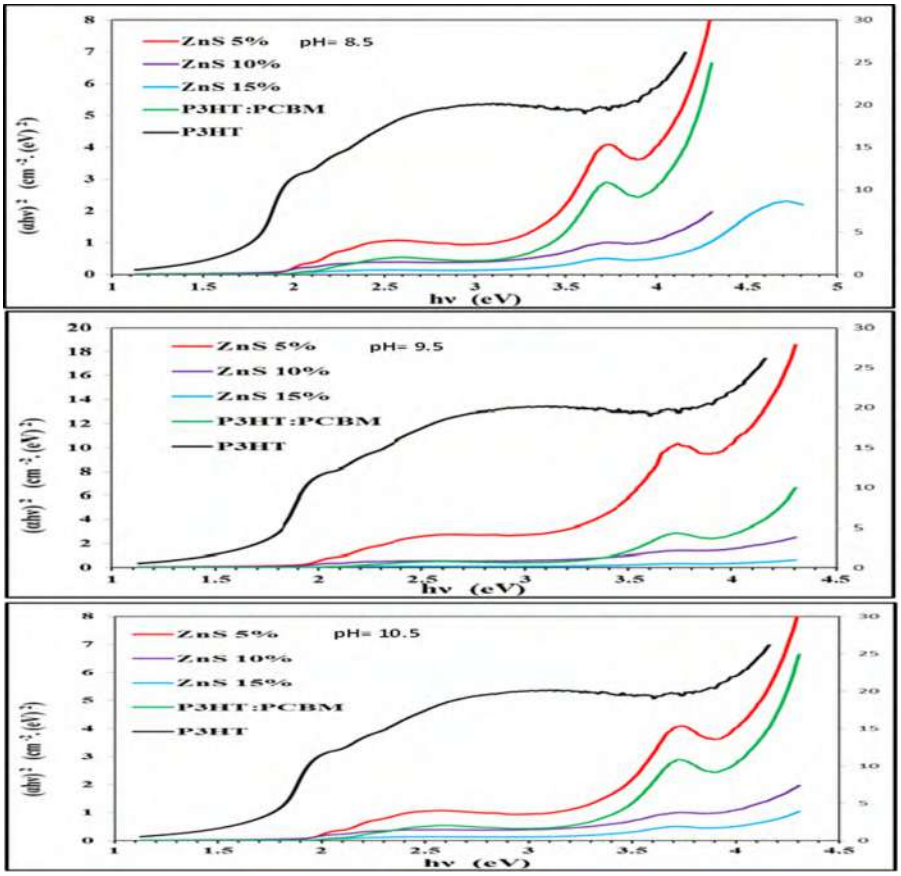

Figure 4. (αhυ) ^{2} versus photon energy (hυ) for P3HT:PCBM:ZnS films with various pH values of ZnS nanoparticles.

Table 1. Optical constants for P3HT: PCBM: ZnS films for different pH and concentration values of ZnS nanoparticles.

pH	ZnS Conc.	Eg (eV) Q1-band	Eg (eV) Q2-band 2-ban	Eg (eV) B-band band
8.5	5%	1.92	1.98	3.26
	10%	1.87	1.92	3.1
	15%	1.92	2	3.2
9.5	5%	1.89	1.94	3.16
	10%	1.8	1.88	3.02
	15%	1.9	1.99	3.04
10.5	5%	1.91	2	3.24
	10%	1.85	1.82	3.23
	15%	1.91	2	3.26

4. Conclusions:

In this work, it is shown that the surface morphology and optical properties of the P3HT: PCBM blend film is influenced by the adding of ZnS NPs on polymer-fullerene matrix. This result is attributed to the interpenetrating network of ZnS nanoparticles which grow in P3HT: PCBM layer. Also, there is an improvement of the light absorption intensity for P3HT: PCBM matrix due to the addition of ZnS NPs material. Hence, it can be used as an active layer to achieve an efficient solar cell.

Abstract. TiO_2 thin films were deposited by Spray Pyrolysis with thickness ((350±25) nm) onto glass substrates at (350℃), and the film was annealed at temperatures (400 and 500)℃ . The structural and morphological properties of the thin films (TiO_2) were investigated by X-ray diffraction, Field emission scanning electron microscopy and atomic force microscope. The gas sensor fabricated by evaporating aluminum electrodes using the annealed TiO_2 thin films as an active material. The sensitivity of the sensors was determined by change the electrical resistance towards NO_2 at different working temperatures (200 and 300) ℃. It was determined that the fabricated sensor using TiO_2 thin film annealed at (400) ℃ with 8.28 nm particle size has high sensitivity than the thin films annealed at 500℃ with 10.37 nm particle size. The sensor operated at 200 °C had also sensitive to the NO_2 gas and its sensivity increased with operated temperatures at 300℃. It was observed that the fabricated sensors exhibited reproducible and stable results.

Keywords: TiO_2; Thin Film; annealing temperature; operation temperature; gas senor; spray pyrolysis.

1. Introduction

The Solid State gas sensors are depends on the change of the physical and/or chemical properties of their sensing materials when exposed to different gas atmospheres. Although the number of materials used to implement this kind of devices is huge, this work will be centered in studying the ones based in semiconductor properties, and more specifically in those using TiO_2 as gas sensor [1].

TiO_2 used in gas sensing is extensively because of its desirable sensitivity and mainly because of its good stability in adverse environments and versatility in detecting a wide range of toxic/flammable gases [2, 3]. Titanium (IV) Oxide (II) has phase stable, rutile (tetragonal) and two phases metastable, brookite (orthorhombic) and anatase (tetragonal). Both metastable phases become rutile (stable) when annealing the material at temperatures above 700 ºC (in pure state) [4].

This Semiconductor Gas Sensors (SGS) present the property of changing the electrical conductivity upon adsorption/desorption of gas molecules at their surfaces. Interaction with ambient oxygen in an n-type SMO can trap mobile carriers (electrons) from the bulk, resulting in an electron-depleted layer (i.e., space-charge layer) at the material surface [2,5].

As suggested by several authors [6, 7], working with nanostructured materials will give a higher surface area in front of gas. Taking into account that sensing reactions take place mainly on sensors layer surface, the control of semiconductor particle size will be one of the first a requirements for enhancing the sensitivity of the sensor.

Previously, reported methods for depositing thin film gas sensing materials include chemical bath deposition [8], spin-coating [9] silar [10], vacuum evaporation [11], sol-gel [12] and RF. Sputtering techniques [13] ,etc. Among all methods, spray pyrolysis method is preferred here because It is a simple method, cheap cost and easily for producing wide area deposition with suitable thickness [14]. The aim of this work was to deposited-TiO_2 thin films using a simple Spray Pyrolysis method and characterizes the effect of annealing temperature operation temperature on their nanostructural and sensor properties.

2. Experimental details

The TiO_2 thin films were prepared using spray pyrolysis method by taking a 0.1 M aqueous solution of TiC_3 as starting solutions. The solution was sprayed on to heated glass substrates which were kept at temperature 350℃. Film thickness (t) was measured using weighting method, and was found to be around (350 nm). The prepared films were annealed for 2h at temperatures 400and 500 ℃. The structure of the films after annealing were determined by X-ray diffraction (XRD) using X-ray diffractometer (SHIMADZU Japan) XRD600) with a Cu Kα radiation source (λ = 1.5406 Å) operated at 40 kV and 30 mA. The samples were scanned from 10 to 80°.

The surface morphology of films after annealing at 400 ℃ and 500 ℃ was carried out using Field emission scanning electron microscopy (FE-SEM) TESCAN (Czech Republic) (Zeiss-EM10C-100KV)university of Tehran -Iran, and Atomic Force Microscopy (AFM) micrographs were recorded by using (Cary 100 Conc plus) university of Baghdad.

Finally, the TiO_2 gas sensor was fabricated by evaporating aluminum as the ohmic contact electrodes on the TiO_2 thin films deposited using a grade mask. The gas sensitivity of a film is usually measured as the percentage change in film resistance on gas exposure, or may be defined as the ratio of its resistance in air to its steady state value in the presence of a gas. After put the sample in chamber was locally manufactured (The chamber is cylindrical in shape, with a radius of 7.5 cm, and a height of 15 cm.

3. Results and discussion

3.1. XRD analysis

The X-ray diffraction of thin films annealed at (400and 500) ℃ are shown in Figure 1 and 2. XRD results showed that the film was tetragonal TiO_2 polycrystalline after annealing according to JCPDS (Card No. 21-1272). It can be seen peaks (101) and (200) at around 25.23^o and 48.10° belong to TiO_2 appear at the annealing temperature of 400°C and slightly deviation in the peak position with increasing of annealing temperature, may be due to the formation of different strain relief at the crystal grains[15] . It is also observed that the peaks intensity increase with increasing annealing temperature, and other weak peaks appear after annealing at 500ºC, also it was found that the tetragonal phase remains stable with increasing annealing temperature, this result agreement with (Hasan et.al)[16].

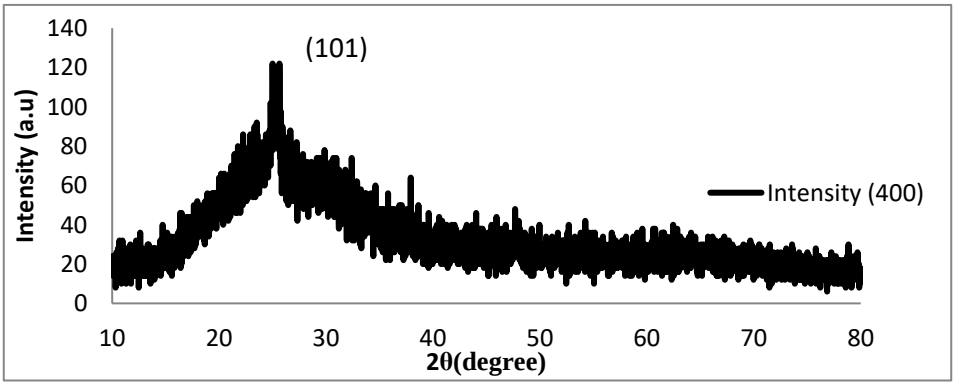

Figure 1. XRD patterns of (TiO_2) films annealed at 400°C temperature.

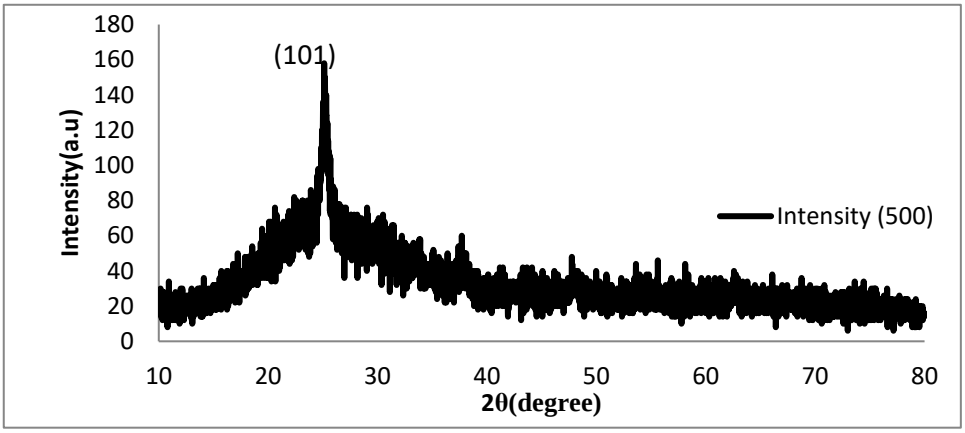

Figure 2. XRD patterns of (TiO_2) films annealed at 500°C temperature.

The XRD peaks (101) was selected to obtain structural parameters such as strain, crystalline size C.S , dislocation density δ and number of crystallites per area are calculated by using the following relations respectively [15,17] and listed in table(1) and influence of increase annealing temp. on the structural parameters.

$$\varepsilon = \frac{\beta \cos\theta}{4} \quad \ldots\ldots\ldots\ldots (1)$$

$$C.S = \frac{0.94\,\lambda}{\beta \cos\theta} \quad \ldots\ldots\ldots\ldots\ldots (2)$$

$$\delta = \frac{1}{(C.S)2} \quad \ldots\ldots\ldots\ldots\ldots (3)$$

$$N = \frac{t}{(C.S)3} \quad \ldots\ldots\ldots\ldots\ldots (4)$$

Where λ =0.154061nm, θ: Bragg's angle, β (FWHM): full width at half maximum in rad and t: thickness of the film.

From the Table 1, it was generally observed that as the crystallite size increases the strain, dislocation density and number of crystallites per area in the film decreases which is a well-known phenomenon.

Table 1. XRD results for thin films.

Parameters		Annealing temperatures ℃		Standard values
		400	500	
2θ	(101)	25.2372	25.1807	25.2806
	(200)	48.1091	47.9392	48.0487
d Å	(101)	3.5261	3.5338	3.5200
	(200)	1.80779	1.89611	1.8920
Strain	(101)	0.00437	0.00349	……..
C.S nm		8.28	10.37	……
δ *10^{15}	m^{-2}	14.5	9.3	…….
N_o *10^{16}	m^{-2}	61.5	31.4	……..

3.2 FESEM and AFM analysis

Figure 3. shows the Field Emission Scanning Electron Microscopic (FESEM) images of the annealed at 400 ℃ and 500 ℃ films. FESEM pattern reveals that films are uniform, good coverage of substrata surface, dense and without any cracks.

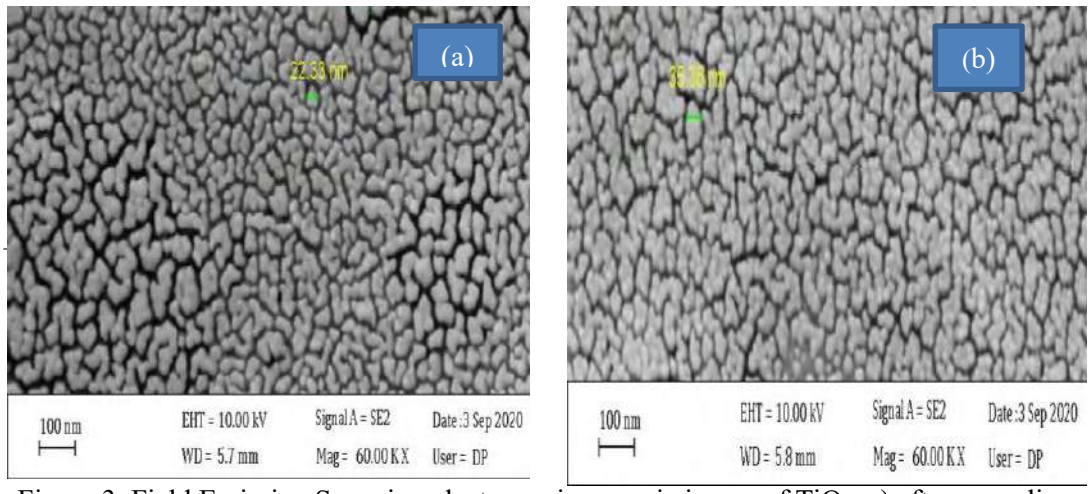

Figure 3. Field Emission Scanning electron microscopic image of TiO_2: a) after annealing at 400 and b) after annealing at 500.

The two -dimensional (2D) AFM images for thin films with annealing temperatures are shown in Figure 4. The sample surface become rougher after annealing at 500 ℃, it increased from 3.53nm for thin films annealed at 400°C to 7.63 nm for thin films annealed at 500°C as shown in table (2) this increasing may be due to increase of grain size. This results agreement with X-ray diffraction and (FESEM).

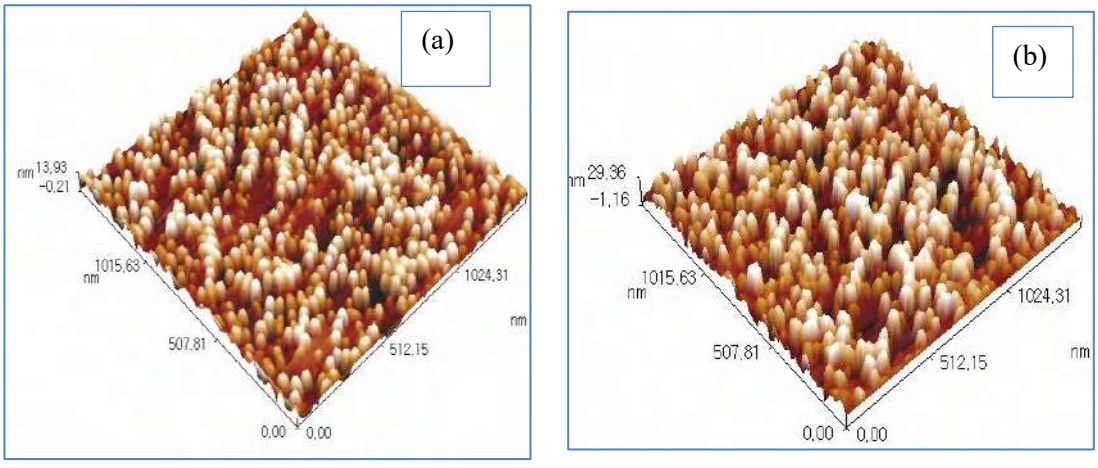

Figure 4. (2D) AFM images for annealing temperatures:(a) 400°C and(b) 500 °C.

Table 2. AFM results for thin films.

Annealing Temp.	Roughness	RMS	Average grain size (nm)
400°C.	3.53	4.08	47.73
500°C.	7.63	8.81	74.03

3.3. The gas sensitivity

The gas sensitivity of a film is usually measured as the percentage change in film resistance on gas exposure, or may be defined as the ratio of its resistance in air to its steady state value in the presence of a gas .Response (or detection sensitivity) of the sensors can be calculated as [18,19].

$$S=\left(\frac{(Rg-Ra)}{Ra}\right)*100\% \dots\dots\dots\dots\dots (5)$$

Where, Ra and Rg are the measured resistance under air and NO_2 (oxidizing gas), respectively.

It is possible to calculate the sensitivity of the sensor of the type metal oxides semiconductor through the interaction between the gas and the sensor surface

3.3.1. Influence of annealing temperature on Gas sensitivity

Figure 5 Shows effect the annealing on sensitivity (S) as a function of operating time for TiO_2 thin films when exposure to NO_2 gas at 200℃ operating temperature. It is clear from this figure the sensitivity of the thin film annealed at 400℃ (particle size of 8.28 nm) is greater sensitivity than of the TiO_2 thin film annealed at 500℃ (particle size of 10.37 nm) because it has a large surface area that provides more active sites for adsorption and reactivation for the gaseous species .And thin film annealed at 400℃ larger roughness, the increasing in surface roughness of the films leads to increase in sensing properties this results agreement with S.H. salman [20].

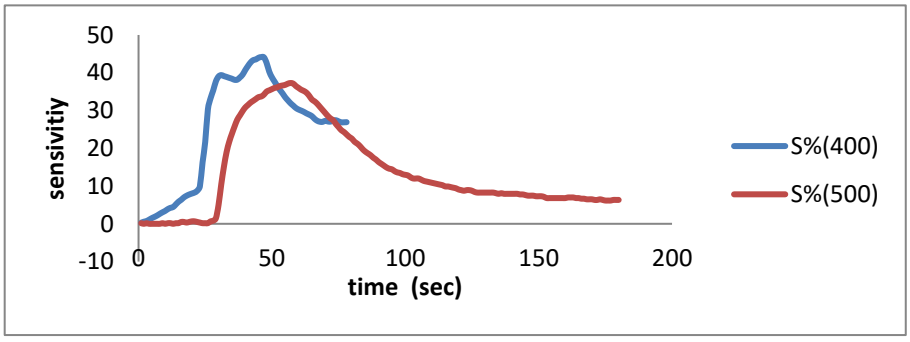

Figure 5. Show the effect annealing on sensitivity (S) as a function of operating time for TiO_2 thin films at 200℃ operating temperature

3.3.2. Influence of operating temperature on Gas sensitivity

Figure 6 and Figure 7 Show operating temperature on sensitivity (S) as a function of operating time for TiO_2 thin films annealed at 400℃ and 500℃ (annealing temperature).

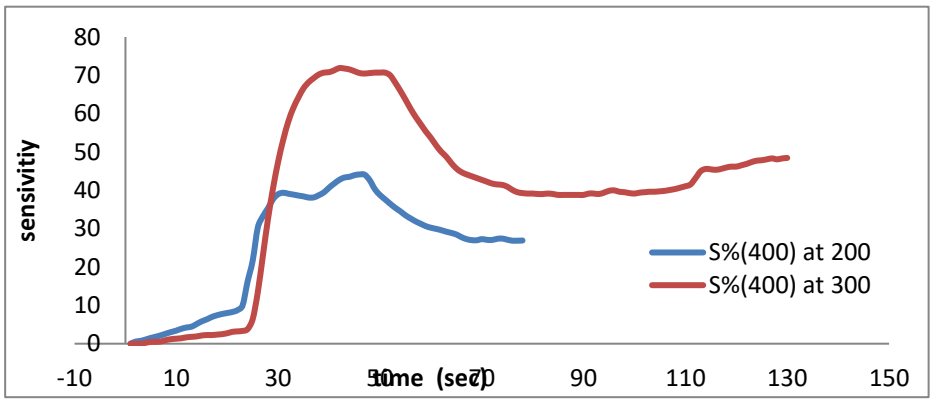

Figure 6 . Shows operating temperature on sensitivity (S) as a function of operating time for TiO_2 thin films annealed at 400℃ (annealing temperature).

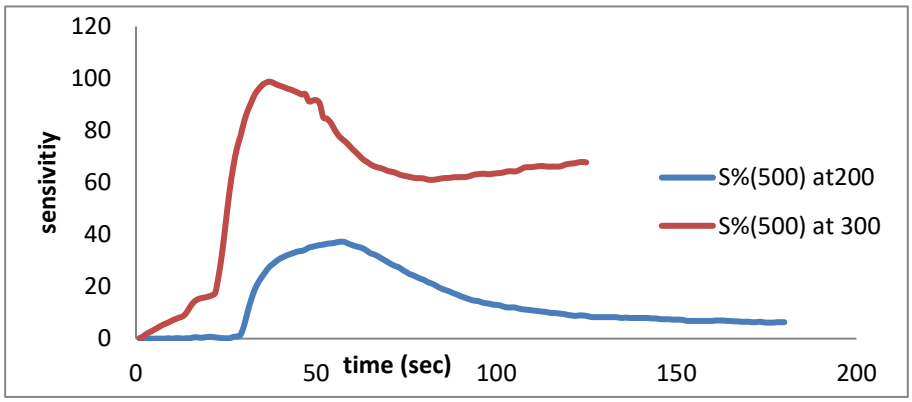

Figure 7. Shows operating temperature on sensitivity (S) as a function of operating time for TiO_2 thin films annealed at 500℃ (annealing temperature).

The calculated sensitivity (S) of the sensors in two cases was given in Figure 5 and 6. The sensor prepared is sensitive to NO_2 gas as seen in these figures. It was shown that the sensitivity of the sensors for these two measurements did not significantly change. As known the stability of the chemical gas sensors related the particle size in the film [21]. It was seen that the sensitivity increased as the operating temperature increased because decreases the surface resistance of the semiconductor thin film. Changing of their electrical properties interested in adsorption of oxygen by trapping an electron from the conduction band of the metal-oxide semiconductor. At the working temperature of the sensor below 200 °C ionized molecular (O_2^-) form of the oxygen can be exist while above this temperature atomic (O^-, O^{2-}) forms is dominated [22].

The highest response of the sensor was reached at an operating temperature of 300 °C, as % 97.4. In addition, the results indicate that the sensor has a good response with 37.46 % at a low temperature as 200 °C; these results for thin films annealed at 500°C.

Also the highest response of the sensor was reached at an operating temperature of 300 °C, as 70.8%. In addition, the results indicate that the sensor has a good response with 43.9 % at a low temperature as 200 °C, this results for thin films annealed at 400°C.

4. Conclusions

The spray pyrolysis method was successfully used to deposit a uniform and homogeneous TiO_2 film. The XRD data reveal that the TiO_2 samples are polycrystalline with tetragonal structure after annealing. The crystallite size is increased as the annealing temperature increases. The properties of TiO_2 thin films are suitable for various technological applications. Such as gas sensor .the sensitivity of thin films (TiO_2) for NO_2 gas depending on annealing and operating temperature.

Abstract. The marshes of southern Iraq are among the most important and largest wetlands in the Middle East and the world are characterized by the freshness of their waters and their environmental diversity. The marshes have undergone many changes during the past decades and to discover and study these changes, remote sensing data will be used as sources of information and data in this study represented by the Landsat 8 satellite images (OLI), the images were collected for years from 2013 to 2019, and by applying remote sensing techniques and geographic information systems techniques, changes in Al-Hammar marsh were detected during the past seven years, the supervised classification method (maximum likelihood) was applied to classify the region Were identified six main categories of the land cover (deep water, shallow water, small cane, large cane, plant, soil) using the software (ENVI 5.3), the final maps were produced for classification using (ArcGIS 10.4.1) software, the results showed Significant change in the water content of Al-Hammar marsh and the increase in the proportion of flooding during the year 2019 to the highest rate since 2013. In addition, the results showed the accuracy and success of the supervised classification method (maximum likelihood) in the classification of images as they are considered the best classification methods, the fastest and high accuracy.

Keywords: Remote sensing, Wetland, Al-Hammar marsh, Supervised Classification, Maximum Likelihood, Overall Accuracy.

1. Introduction

Remote sensing is an important and pervasive technology in modern technology science, as this technology can be used and applied to collect data about a target such as the features of the land cover and others and this data is analyzed, interpreted and processed to obtain information from it without direct contact with the target, and remote sensing can be defined as a technique Collecting data on a specific target, such as the Earth's surface, analyzing, interpreting, and processing it and extracting information from it without an actual connection between them[1][2]. It provides a great possibility to monitor and collect data about a specific area or goal for different time periods at the same time and with high accuracy and with simple costs for the purpose of analyzing, interpreting and studying them and discovering the changes that occur during these periods and many other processes provided by this science, it allows the possibility of studying the features of the land cover [3]. These data collected about the target are transferred from the target to the sensor in the form of electromagnetic spectrum as the physical medium between the target and the sensor is the electromagnetic spectrum [4]. In remote sensing, several areas of the electromagnetic spectrum are used through the sensed images where remote sensing deals with both the visible spectrum, the infrared (near, short and thermal) spectrum, the

microwave, where these images are collected from sources Numerous such as satellites, radars, spacecraft or sensing images carried on board aircraft [5][6]. The wavelengths of these areas of the electromagnetic spectrum are reflected from the target and recorded as a digital number in the image pixels as the images that are dealt with in this technique are multi-spectral digital images that consist of a large number of picture elements (pixels) as each pixel has a specific digital number It represents the amount of the reflected electromagnetic spectrum from the target, the pixel in the image covers a specific area of the region covered by the image[5][7].Remote sensing provides many and important data on the surface of the earth and its resources, and thus it represents an important and great source for many studies and applications that address the surface of the earth and its various and various features. Urban development, agriculture, and many other applications, using remote sensed data [8][9]. One of the important applications in remote sensing is the study and discovery of changes that occur in wetlands that affect their nature. The diversity in the environmental system and have a great importance in maintaining the balance and presence of wildlife. It is low areas on the surface of the earth that are submerged in water that are either deep or shallow in which many plants grow. These lands may be permanently submerged or seasonally and form a good habitat for different animals such as fish, migratory birds and many other animals. Wetlands exist in different forms on the surface of the ground Including swamps, marshes, shallow lakes, etc. They also differ in terms of the nature of the waters that are submerged, some of which are fresh and salty, and they represent an integrated ecosystem in biological terms, and they are either natural existence or artificial, wetlands constitute about 3-6% of the surface of the earth around the world and represent one of the main ecosystems on the earth's surface [10][11]. Among the important and major wetlands in the world are the Iraqi marshes, which are characterized as natural wetlands with fresh water. These marshes cover a large area in southern Iraq, where they occupy south and central the sedimentary plain in three southern governorates: Basra, Maysan, and DhiQar[12][13]. It also represents the largest natural wetland in the Southwest Asian region [14][8]. There are many marshes in southern Iraq, including permanent ones and seasonal ones, but mainly wetlands in Iraq can be represented by three major and large marshes: Al-Hammar marsh, Central Marshes and Hawizeh marsh [15]. The Iraqi Marshes have undergone great changes during the past forty years for a number of reasons, including drying and building dams, etc., which led to changing many of its features, characteristics, flooded areas, and even its environmental system and biological composition [16]. To study the changes that occurred in Al-Hammar marsh during the time period of 2013-2019, remote sensing and geographic information systems (GIS) techniques are used where the supervised classification method (maximum likelihood) will be used to know the change in the water content and the areas flooded during this period and is this is done by performing image processing on Landsat satellite images (L8), where image processing represents all the processes and applications that are implemented on digital images for analysis, processing, interpretation, and extracting the required information through the use of computers, for image processing multi applications on remote sensing images as classification, environmental assessment, changes detection taking occur in the land cover features and create maps and other [5].The use of land cover in Dhaka Metropolitan of Bangladesh is studied by using the same supervised classification method as the maximum likelihood of classifying the sensed data and revealing the changes taking place in the region, Dewan 2008[17]. The same objectives of this study but using another program to apply the supervised classification to detect changes is the program (ERDAS), Abdul Jabbar and others 2010[16]. This study is similar to the current study where the supervised classification method (maximum likelihood) is used to classify attributes of the study area and reveal the changes that occurred in it, Soliman 2011[18]. The Landsat satellite imagery is categorized in the same way in this study to uncover changes in Kolkata Wetlands, Seema and others 2012[19]. Similar to the work of this study, where the study area is classified using the supervised classification method (maximum likelihood) and then revealed the changes that occurred, Muhsin and others 2017[13].

2. Classification

Classification is an important application in remote sensing and in image processing, where images are processed and some algorithms are applied to them in order to obtain certain information, and classification can be defined as the process of sorting and distributing image elements (pixels) on the features or classes of land cover based on the numerical value of the units of the image, as each of them possesses a numerical value representing the amount of spectral reflection of the attribute or class present in the image [20]. The classification is very important when dealing with multispectral images that consist of a number of spectral bands, and there are two main types of classification are supervised classification and unsupervised classification [21].

The supervised classification is considered the fastest, broader in use and application and the highest accuracy than the unsupervised classification, it gives very accurate results and close to the reference data that are compared with it when applied by a user with experience and good knowledge of the classified area and the land cover features for it, the supervisory classification provides great potential and freedom for the user in The identification and distribution of image pixels on the land cover categories, it makes the classification process easier and faster, and this type of classification needs in the beginning to identify and choose training sites in the area of interest, i.e. distribute the image pixels to the land cover categories It is distributes according to the spectral reflection of each of them, and then each training site is distinguished by a specific color or symbol, so that it can separate and define the interference regions in the land cover [21][22]. There are many types of supervisory classification including (parallelepiped, minimum distance, mahalanobis distance, maximum likelihood, spectral angle mapper, spectral information divergence, Binary encoding), where the maximum likelihood method will be used in this research paper to classify the Landsat 8 satellite images [23].

3. Maximum likelihood Classification method:

It is the most common and used method and the most accurate supervised classification method in the classification of remote sensed images as it is widely used to classify the features of the land cover in images with false colors, in this method all pixels in the image are classified and assigned to one of the categories of the land cover that have the highest probability [24][25]. In order for the results to be very accurate, the probability threshold limit that does not allow a pixel to be set to a category with a low probability [26]. Must be set. The discrimination functions for all pixels in an image classified in this way are calculated using the following formula:[27].

$$\boldsymbol{g_i}(x) = In\, p(\boldsymbol{\omega_i}) - \frac{1}{2}\, In \left| \boldsymbol{C_i} \right| - \frac{1}{2}\, (x - m_i)^T \boldsymbol{C_i^{-1}} (x - m_i) \qquad \ldots\ldots\ldots\ldots\ldots (1)$$

Where:i: classes. x: dimensional information.$P(\omega_i)$: Probability of occurrence of the class in the photo (presumably the same for all categories).$|C_i|$: Specified for the information covariance matrix in the category(ω_i).C_i^{-1}: Inverse of covariance matrix. m_i: The image classes mean vector.

4. Classification accuracy assessment

Despite the high accuracy of the classification and the proximity of the results of the classification to the real reference data for the study area or the classified target, it is necessary to verify the accuracy and validity of the classification by conducting an assessment of the classification accuracy, which represents an important and final step in the classification process that shows how accurate the classification. Confusion matrix (error matrix) is constructed, which is a matrix consisting of numbers (rows and columns) these numbers represent the classified image units where image pixels (number of image units) classified for each category of land cover are placed in one of the rows and the reference data for each category of land cover is placed in One of the columns for the matrix [28]. There are several methods for assessing classification accuracy such as user accuracy, product accuracy, overall accuracy, and Kappa coefficient. The overall accuracy is the ratio between correctly rated reference points to total reference points [28]. The accuracy of the user is the ratio between the numbers of pixels correctly classified to the total number of pixels in the row, while the product accuracy is the ratio between the numbers of pixels classified correctly to the total number of pixels in column [29]. Thus, the confusion matrix can be written using product accuracy and user accuracy [28]. Another metric that

represents a statistical measure of classification accuracy is the Kappa coefficient that has a value between + 1 and -1, so whenever the classification accuracy is high and is close to reference data, its value is close to + 1, if either its value is close to zero or negative, then this means that the classification is inaccurate and there is no affinity between it and the reference data. To calculate the overall accuracy, equation (2) is applied. To calculate the Kappa coefficient, equation (3) is applied, respectively [30].

$$\text{Overall accuracy} = \frac{\textbf{Total number of correct classified}}{\textbf{Total number of pixels}} * 100 \quad \dots\dots\dots\dots\dots (2)$$

$$K = \frac{n \sum_{i=1}^{p} xii - \sum_{i=1}^{p} (xi \times x+i)}{n^2 - \sum_{i=1}^{p} (xi \times x+i)} \dots\dots\dots\dots\dots (3)$$

Where:
n = total number of training pixels. p = number of classes. Σxii = total number elements of confusion matrix. $\Sigma xi+$ = sum of row i. $\Sigma x+i$ = sum of column i.

5. Study area

Al-Hammar marsh is considered one of the main marshes in Iraq and occupies a wide area that extends across three governorates (Basra, DhiQar, Maysan), approximately 300 km south of Baghdad and is located within the coordinates of latitude (31,00 - 31,30) north and longitude (46,24 - 47,18) east, with a length of about 90 km either its width ranges between (25-30) km, ALHammar marsh is a distinctive and important ecosystem with social and economic impact in the region and has great importance and benefit as it represents the habitat for many migratory birds in addition to that the local population depends in their livelihood on the resources of marshes and animals [31].

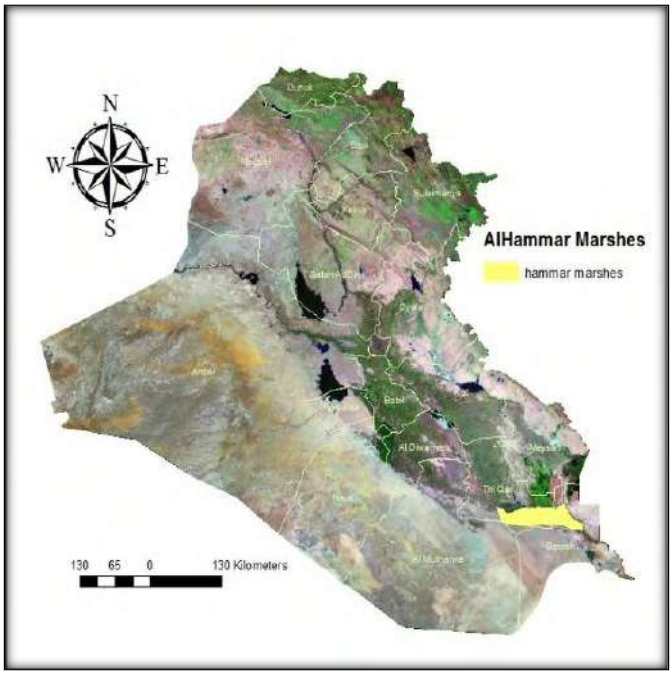

Figure 1. Al-Hammar Marsh – Iraq

Methodology

In this study, the changes that occur in the Al-Hammar marsh south of Iraq during the time period from 2013 to 2019 are revealed using remote sensing techniques and geographic information systems(GIS), where the study included classification of the study area and detect the changes in the water content and the percentage of submerged areas of the marsh and the factors causing changes, Using the Landsat 8 satellite images data and comparing it with the reference data taken from the Ministry of Water Resources, the Landsat 8 satellite advantage is that the images provided by it consist of 11 spectral bands

distributed over two sensors, the first is the Operational Land Imager (OLI) and the second is the Thermal Infrared Sensor (TIRS), the sensor (OLI) senses the first nine bands either the sensor (TIRS) it only senses the last two bands [32][33]. Satellite images with 30m spatial resolution was collected from the United States Geological Survey (https://www.usgs.gov/) website covering the study area with two scenarios and coordinates (Path 166 - Row 39) and (Path 167 - Row 39) all taken during July and for all years that are within the studied time period of 2013-2019 with varying dates. As shown in Table (1) and Figure 2.

Table 1. Landsat imagery used in the study

Sensors	WRS Scene	Acquisition Dated
Landsat 8	Path 166 Row 39	28/07/2013
Landsat 8	Path 167 Row 39	19/07/2013
Landsat 8	Path 166 Row 39	31/07/2014
Landsat 8	Path 167 Row 39	22/07/2014
Landsat 8	Path 166 Row 39	18/07/2015
Landsat 8	Path 167 Row 39	25/07/2015
Landsat 8	Path 166 Row 39	20/07/2016
Landsat 8	Path 167 Row 39	27/07/2016
Landsat 8	Path 166 Row 39	23/07/2017
Landsat 8	Path 167 Row 39	30/07/2017
Landsat 8	Path 166 Row 39	26/07/2018
Landsat 8	Path 167 Row 39	17/07/2018
Landsat 8	Path 166 Row 39	29/07/2019
Landsat 8	Path 167 Row 39	20/07/2020

Figure 2. Satellite images for Al-Hammar marsh – Iraq at 2013 before and after mosaic.

The experimental steps of this work are summarized in the following: Mosaic: which is the process of merging the images overlapping with each other in a way that allows the production of a new image covering the entire study area, each band from the first scene was merged with the band that corresponds

to it from the second scene in the mosaic method. After that, the numeric values of the Landsat 8 satellite images are converted from digital number into reflectivity using equation (4) [34].

$$\boldsymbol{\rho\lambda = (M\rho * Qcal + A\rho) / sin\theta} \quad \ldots\ldots\ldots\ldots\ldots (4)$$

Where:
$\rho\lambda$ = Top of Atmosphere Planetary Reflectance. (Unit less).
$M\rho$ = Reflectance multiplicative scaling factor for the band.
$A\rho$ = Reflectance additive scaling factor for the band.
$Qcal$ = Level 1 pixel value in DN.
θ = Solar Elevation Angle.
Corrected spectral bands are combined by layer stacking using (ENVI 5.3) software to obtain multi-spectral images (stacked). The color combination (543) is chosen as a color image in pseudo colors, it represents a color image in the form (RBG) with three spectral bands from the Landsat 8 satellite image (near infrared band, red visible band, green visible band), and these are chosen The color combination, because it is the most suitable color combination, to show the main features of the land cover of the study area which are (water, cane, plant, soil) as shown in Figure (3). The cane has different spectral reflectance than the plant and the cane growth inside the marshes, so, it should be separated.

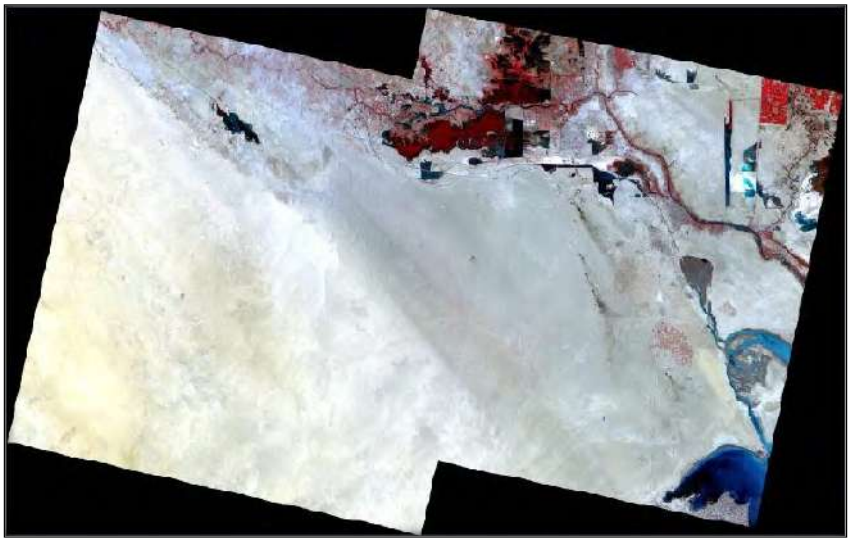

Figure 3. Color combination (543) applied to Landsat 8 satellite images.

Al-Hammar marsh's area is cut off from the resulting image because the image covers a much larger area than Al-Hammar marsh's area and performs the cutting using (ArcGIS 10.4.1) software by creating a shape file for the boundaries of Al-Hammar marsh. Regions of interest (ROIs) are determined by using (ENVI 5.3) software. Six categories of land cover for the area are identified (deep water, shallow water, small cane, large cane, plant, soil), then the digital classification of the satellite images in which the categories were identified the supervised classification method (maximum likelihood), as shown in Figure 4.

6. Results and Discussion

The results obtained by conducting the methodology on the classified images that were conducted to change detection in the water content and the submerging ratios of AL-Hammar marsh in southern Iraq during the period from 2013 to 2019.

Figure (5) represents the outputs of the supervised classification process (maximum likelihood) that classified the land cover of the study area (deep water, shallow water, small cane, large cane, plant, soil), after the classification procedure, the percentage of the water area is calculated by Collecting percentages for each area (deep water, shallow water, small cane) and for all years respectively, Table (2) shows the percentage of the area of each of the swamp areas, graph (1) shows the change in the water level in the marshes.

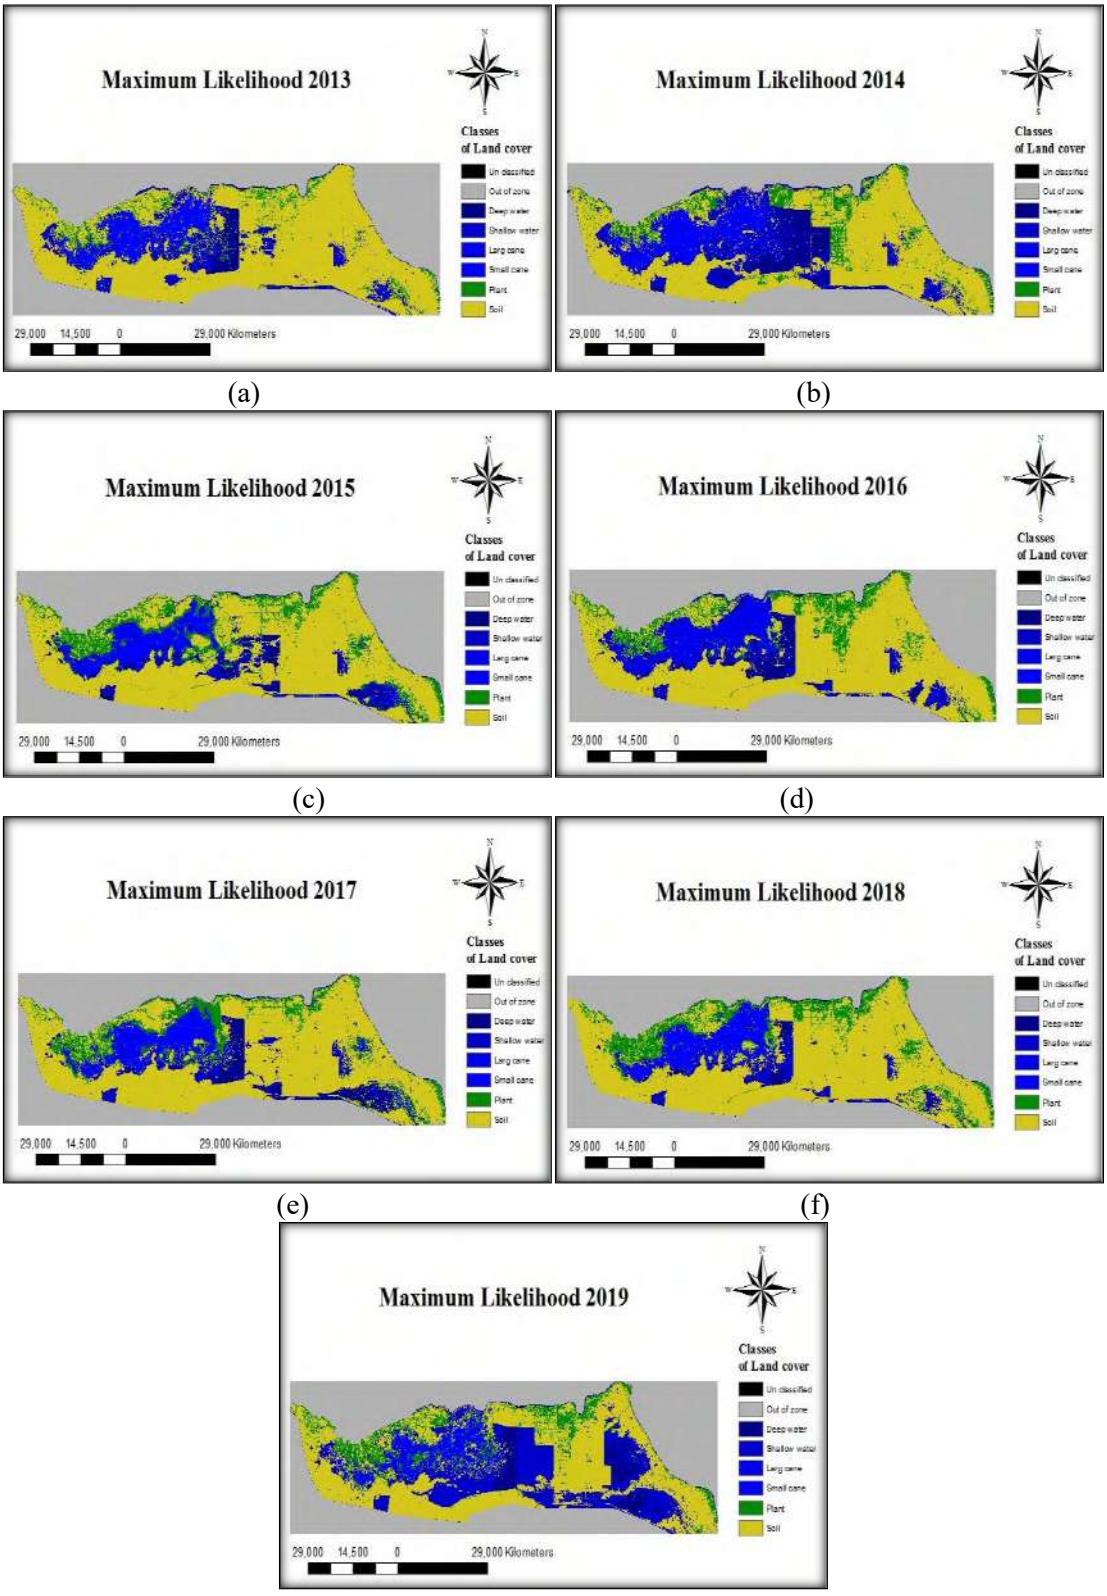

Figure 5: Supervised classification (maximum likelihood) of color combination (543) for years (a. 2013-2013 b. 2014 c. 2015 d. 2016 e. 2017 f. 2018 g. 2019).

Table 2. The class's area for Supervised classification (maximum likelihood) of color combination (543) for the years 2013 – 2019.

Classes / Year	Unclassified m²	Water m²	Cane m²	Plant m²	Soil m²
2013	0	791,687,700	19,880,100	197,136,900	2,236,341,600
2014	0	1,067,350,500	123,702,300	285,183,000	1,768,810,500
2015	0	667,788,300	37,149,300	463,361,400	2,076,747,300
2016	0	423,976,500	425,566,800	368,420,400	2,027,082,600
2017	0	746,451,900	55,395,000	394,592,400	2,048,607,000
2018	0	671,757,300	3,850,200	446,243,400	2,123,195,400
2019	0	1,269,193,500	36,064,800	368,053,200	1,571,734,800

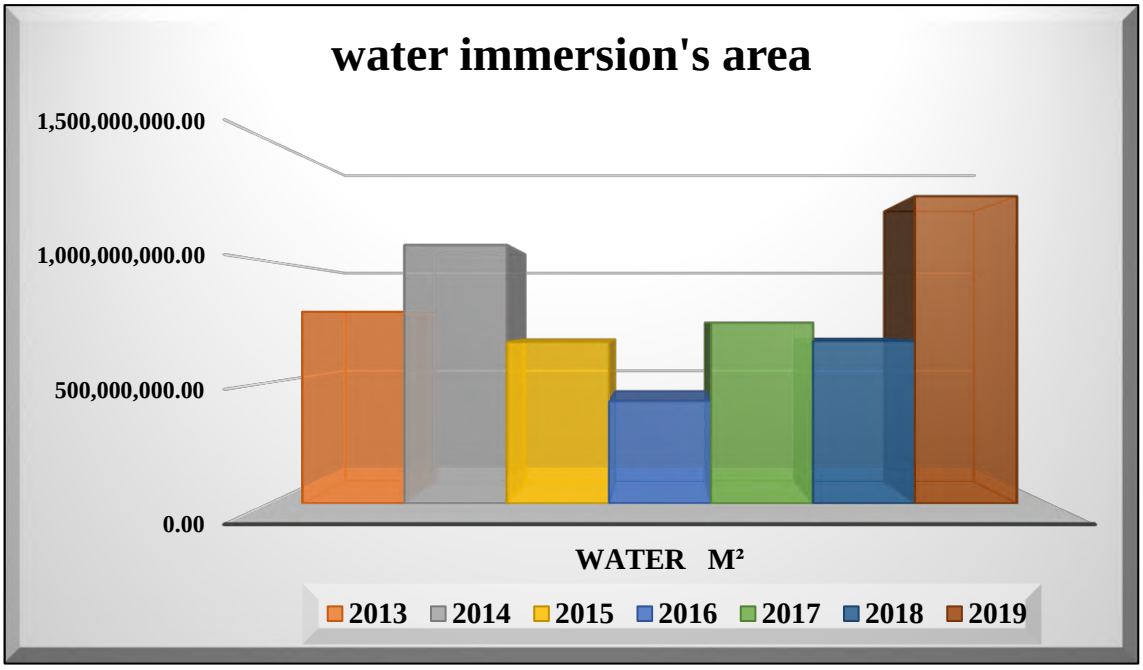

Figure 6. The Differences in the surface area of the water content in Al-Hammar marsh versus the years 2013 to 2019.

the results that appeared to us and by studying the figures and tables mentioned above, when comparing with reference data taken from the Ministry of Water Resources for the study area, we find that the color combination that was chosen and the classification method used to classify the satellite images, which is the supervised classification method (maximum likelihood) gave high accuracy results very close to Real data and what confirms this are when conducting an assessment of classification accuracy and calculating the overall accuracy and Kappa coefficient for all the classified images, a very high accuracy was obtained, as shown in Table (3). where it was found that there were a lot of changes that occurred in Al-Hammar marsh as the water content and the inundation percentage , as these rates varied during the successive years from 2013 to 2019 by increasing and decreasing, where we note that the percentage of water content rose slightly in the year 2014 from what was during 2013 either during the subsequent years either the percentage of water began to decline gradually and unevenly reached the lowest in the

year 2018, where the water covering the area of the marsh became scarce, and since the beginning of the year 2019 the percentage of water began to increase in the marshes significantly, until in May it reached twice what it was during the same month of 2018 as a result of the flood wave and torrential rains that swept the country.

Table 3. Overall accuracy values and Kappa coefficients for supervised classification methods in color combination (543) for all years.

Year	Overall accuracy	Kappa coefficient (K)	Error percentage
2013	98.9698	0.988	1.0302
2014	99.9323	0.9992	0.0677
2015	99.9324	0.9992	0.0676
2016	85.6017	0.8324	14.3983
2017	99.6608	0.996	0.3392
2018	96.2526	0.9562	3.7474
2019	99.862	0.9984	0.138

7. Conclusions

We conclude from the results obtained that the color combination (543) chosen in this study, which is the spectral bands (near infrared band, red visible band, green visible band) are the best color combinations that can be applied to determine the features of the land cover of the marsh region, as the required features are well and clearly demonstrated, in addition to that we conclude that the supervised classification method (maximum likelihood) is the best and most accurate classification method that has been applied to classify the land cover features in an easy, fast and highly accurate manner because it gave very close results to the reference data with a very low error rate, reaching 0.0676%.

Abstract. The heavy elements (Cadmium, Mercury, and Arsenic) are considered to be highly toxicity for human and living creatures. This research focused on the concentrations of these elements in the soil of Diyala Governorate. The 25 samples of soil were collected from different areas included (industrial, residential, and agricultural) with an average sample rate for each region with a depth (10 cm). The samples were compressed to prepare them for measurement by dispersive spectroscopy of X-ray energy (EDX).The results are compared with the global determinants World Health Organization (WHO), where the results indicates the highest concentration of cadmium in the Injanah region and the lowest concentration in the Alma'amil region. The highest concentration of mercury in the regions of Mohammed Sakran and Diyala Bridge and the lowest concentration in the region of Mundhiriyah. The Arsenic elements concentrated become high in the Rashidiya region and less concentrated in the Hamrin hills region. It is known that these elements are more toxic than other elements when they are found in a higher rate than the permissible level in the soil.

Keywords: Cadmium, Mercury, Arsenic, high toxicity, and soil elements.

1. Introduction

The general meaning of heavy elements is those elements with a density greater than (5g/ cm3) [1]. The soil in many regions of the world is exposed to pollution by toxic heavy elements as a result of human activity in many areas, especially industry and agriculture, adding phosphate fertilizers, manufacturing and mining. These activities are a great source of air pollution that loaded the air particles with heavy elements, so these particles are deposited directly on the soil surface, then by rain it will be transported into the soil. The soil pollution is affected by the plants that been cultivated in this area. The pollutant elements are entering the plants which will be harvested to get into the food chain, and that increases the risks to human health [2, 3].

Cadmium (Cd) which is a metallic silver-colored white substance with atomic number 48 and atomic weight 112,41g/mol. Its boiling point is 765 ° C, its melting point is 321 ° C, and its density is 8.65 g / cm3. The cadmium is a metal and is ignited by heating giving CdO, which is a brown oxide. As for physically, it is satin (malleable and withdrawn) [4, 5].Cadmium is found in ordinary soils with a small concentration of 0.5 ppm or less, but in sedimentary soils its concentration may be 25 ppm One of the properties of cadmium is that it is very stable in the environment and accumulates in the soil where

living organisms coexist and can be easily absorbed from the roots of plants. It is known that cadmium is a toxic element associated with zinc extraction and other industrial processes. However, it is a dangerous air pollutant (cadmium dust), and thus cadmium accumulates on the soil surface and accumulates in plants, including herbaceous plants, without toxic symptoms, and the amount of cadmium in the environment is increased by the disposal of solid waste. Contamination of soil surface, subsurface areas and water surface results in cadmium. Also, the amount of cadmium in the soil may increase as a result of the application of fertilizers [6, 7].

Mercury (Hg) is a chemical element symbolized by Hg, atomic number 80 and molecular weight 200.59 g / mol. Its density (13.54 g / cm3) freezes at (-38.9 ° C), and its boiling point (356.9 ° C). , Which is a silver, bluish liquid that looks like lead in appearance. When an electric spark passes through mercury vapor, it emits a bright flash and ultraviolet light. It evaporates at room temperature and thus its atoms are mixed with the air without the human being realizing it, especially since it has no odour and color, and when a person inhales this air, the mercury atoms enter the lung and thus reach the blood and brain. Many studies have shown that high exposure to mercury causes toxicity to the central nervous system, which can lead to irritability, fatigue, behavioral changes, convulsions, headaches, hearing loss, loss of perception, and hallucinations to death.[8,9]

Arsenide (As) and atomic number 33 in the periodic table of elements. Its atomic mass is 74,922 in the fifteenth group of the periodic table. Arsenic is found in many chemical compounds, as well as a pure crystalline component, and has been achieved in conjunction with minerals and sulfur. Arsenic is a semi-metal, has a multi-rootedness, but the gray form is important in the industry. It was known to be one of the most toxic substances, and was often used to get rid of enemies due to its easy accessibility.It can be detected easily regardless of trying to clean tools used in the arsenic handling and transport process. Arsenic is naturally found in soil, air, and water. In some countries, arsenic is found in large quantities in groundwater. It is very toxic when present in an inorganic form. Table 1 represents the general permissible limit for the presence of elements (Cd, Hg, As) in the soil of the World Health Organization [10].

Table 1. General permissible limit for elements (Cd, Hg, As) in the soil by WHO

Element name	Cd	Hg	As
WHO(mg/kg)	1	0.5	20

2. Geographic Information Systems (GIS)

It is the science that is defined by collecting, processing and analyzing spatial data. There are several programs used for geographic information systems, including those that operate on a directional information system such as ArcGIS and that operate on a raster system such as ERDAS. The trend system is more suitable for storing high-precision data such as ownership and boundary maps, so it is preferable in these cases to choose programs that run on the vector information system [11-13].

3. Interpolation

There are several interpolation methods, such as Kriging, global polynomial, local polynomial, inverse distance weight (IDW) etc. Spatial interpolation is the process of using points with known values to estimate values at other unknown points. For example, to create a precipitation map for a country, you won't find enough weather stations to cover the entire region. Spatial interpolation can estimate the temperature at locations without data recorded using temperature readings known at nearby weather stations calculated using internal interpolation. In GIS, spatial interpolation of these points can be applied to create a vector surface with estimates values. The results of the interpolation analysis can then be used for analyses the whole area and for modelling. There are many methods for implementation in ArcGIS. Inverse Distance Weight (IDW) interpolation method, is one of many methods of interpolation.

The sample points are weighted during interpolation such that the influence of one point with respect to other declines with distance from the unknown point you want to create [12,14,15].

4. Study Area

Diyala Governorate is located in the eastern part of central Iraq, and from the provinces that have international borders, it is bordered to the north by the Sulaymaniyah Governorate and part of the Salahuddin Governorate, while it is bounded to the west by the Baghdad and Salahuddin governorates and to the south by the Wasit Governorate and To the east is the Islamic Republic of Iran.This region situated between (33.3–35.6) latitude and (44.22–45.56) longitude, as shown in Figure 1.

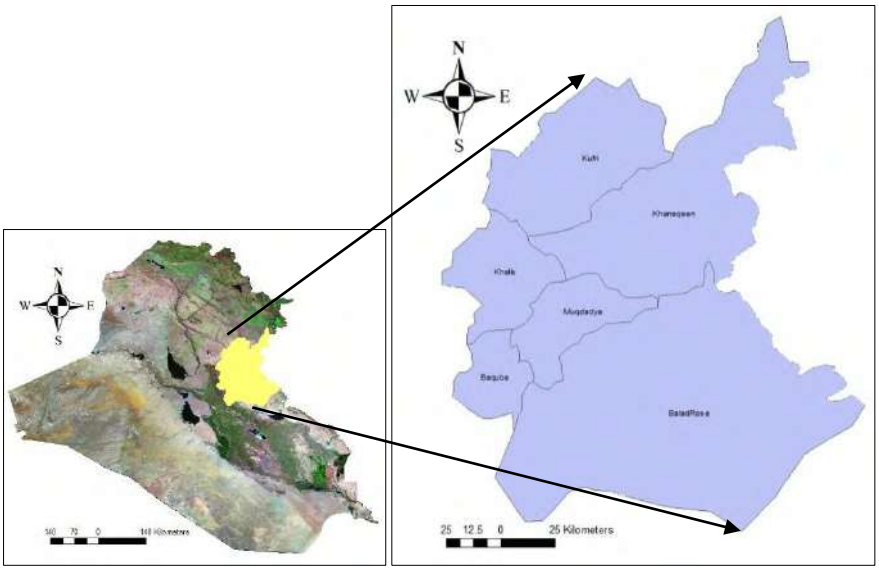

Figure 1. Photomap of Iraq and DiyalaShapefile

5. Modeling and working methods

The work in the current study is divided into three phases:
First stage: is the field work (collection of samples).
Secondstage: is the laboratory work.
Third stage: is the information processing and discussion.
Figure 1 displys Diyala map, which represents the borders of the study area as well as the areas from which samples were collected for the purpose of the study.Twenty-five (25) soil samples were collected from Diyala governorate at a depth of 10 cm. These samples were taken from many regions (industrial, residential, agricultural). The samples were configured by numbering the nylon bags that consists of the samples. The samples were transferred to the laboratory for the purpose of preparing them for measurement to study the concentrations of the heavy elements (Cd, Hg, As).

The work's procedure is summarized by:
Drying the samples in the sun for several days.
Grinding the samples separately: very fine grinding using a ceramic mortar for two hours.
Compressing the soil samples using a hydraulic press,
Finally, examining the concentration of heavy elements in the samples by the (EDX). Table (2) illustrated the location were the samples collected.

Table 2. Symbolized sampling locations

6. Results and discussion

The results gained from the EDX are the concentrations of each elementsin the samples. These data were illustrated in Table 3. The results showsthe variations of the presence of the elements at different locations. The variation of the concentration is a reflection of the pollution degree in that area due to the presence of industrial activities or any human activities.

Geographic information analysis provides the ability to estimate variables throughout the studied area using interpolation functions. The IDW interpolation method was chosen to be applied to the data collected. Figure 2 represents the estimation of cadmium concentration in the studied areas. Through the estimation map, using ArcGIS software, areas were calculated and illustrated in Table 3. The highest concentration of cadmium. It was recorded in Region No. 1 (7.3 ppm) and in Region No. 2 (10.5 ppm) No. 10 it was recorded (4.9 ppm) and in No. 11 it was recorded (8.06 ppm). And in No. 15 it was recorded (7.86 ppm). And at No. 11 it was recorded (8.06 ppm). And in No. 15 it was recorded (7.86 ppm) and in 17.21 4.46, 5.1 of the cadmium element were recorded in these areas due to the nature of the earth's formation, as well as the reason for throwing industrial waste containing cadmium waste as she the Figure(2).

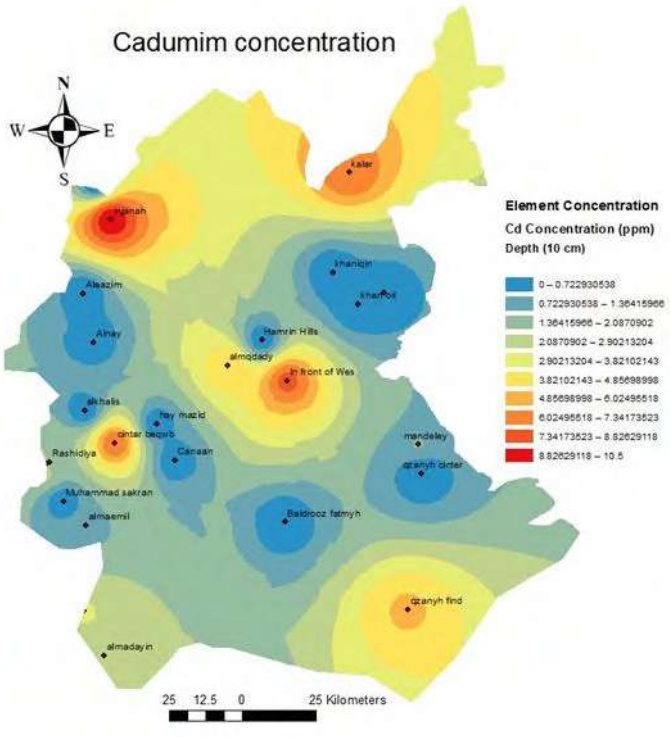

Figure 2. Distribution of Cadmium concentration

The highest concentration of (Hg) was recorded in Region No. 11 (1.53 ppm), while in Region No. 21 (1.13 ppm), and in Region No. 24 (1.26 ppm), it was recorded in Zone 25 (1.02 ppm). Per million), and these four regions are high compared to the (World Health Organization). Adult (0.5 ppm) As for the rest of the regions, the mercury concentration was within or below the required level as shown in Figure 3, which indicates the presence of mercury in the study area. Mercury is naturally present in the earth's crust, and it is released into the environment due to volcanic activities and human activity, which indicates the main reason for the release of mercury into the environment are, especially, from coal-fired power plants, coal burning in homes, cooking, industrial activities and waste incinerators as shown in Figure3.

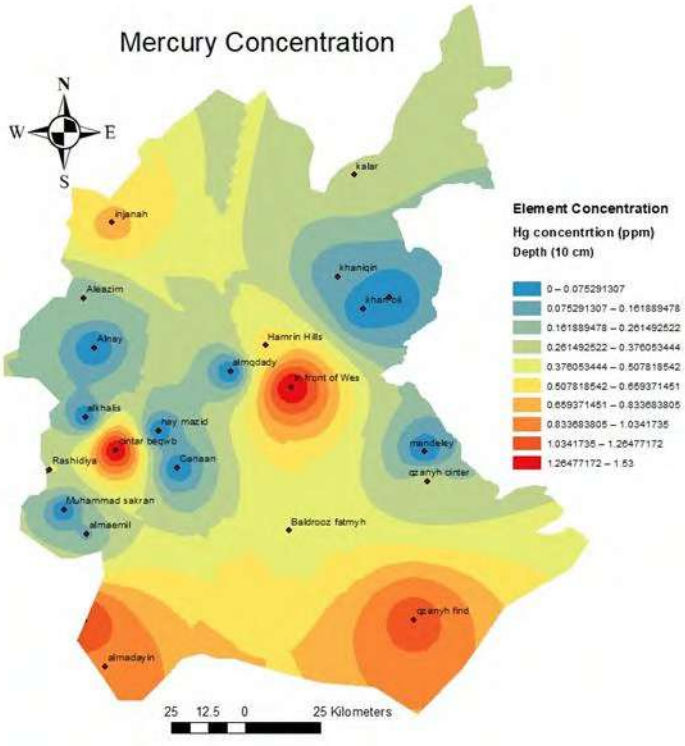

Figure 3. Distribution of Mercury concentration

The highest rise in arsenic was recorded in region No. 8 (38 ppm), in region No. 6 it was recorded (32 ppm), in region No. 11 and in region No. 12 it was recorded (33.33 parts per million). In region No. 18 and recorded the highest rise (61.3 ppm)

As for the rest of the regions, there was no presence of arsenic (Figure 4) representing the sites of arsenic and its concentrations in the studied areas, and the arsenic increases in the areas most used in the industry as an ingredient in the manufacture of alloys, as well as in the treatment of glass, dyes, textiles, paper, metal adhesives and preservatives for wood and ammunition. . Arsenic is also used in leather tanning and, to some extent, in pesticides, food additives, and pharmaceuticals.

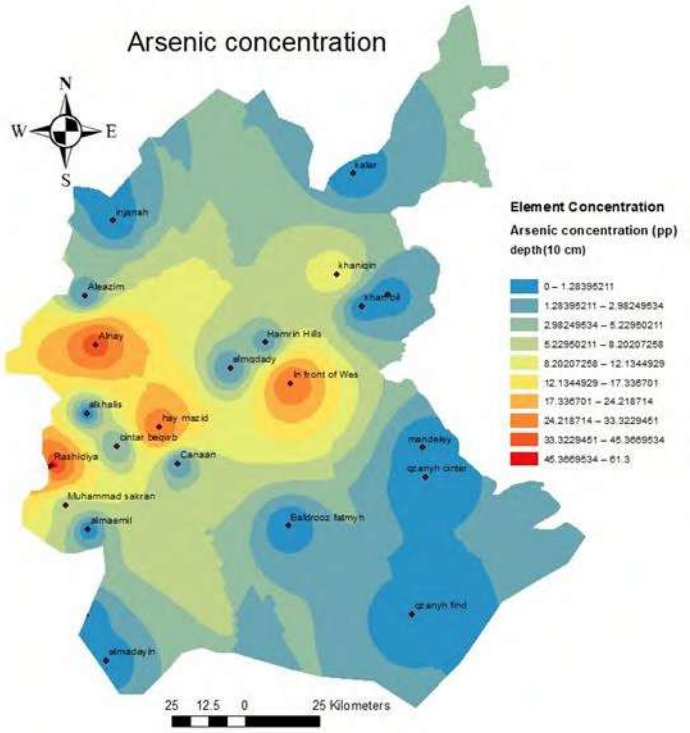

Figure4. Distribution of Arsenic concentration

7. Conclusion

A high concentration of most heavy elements in depth (10 cm), which indicates the absence of movement and transmission of these elements through the soil layers.Soil samples showed contaminated with cadmium, which reached the highest concentration (10.4) compared to the permissible limit (1 part per million) in area No. 4 and the highest concentration of mercury, which reached (1.53 part per million) compared to the maximum. Allowed by the World Health Organization (0.5 part per million) in the 11 and 15 regions, and the highest concentration of arsenic in the 18th region, reaching (61.3 parts per million) compared to the permissible limit of the World Health Organization (20 parts per million).

Soil is often contaminated with cadmium, mercury, and arsenic due to the use of agricultural pesticides and chemical fertilizers that contain these elements. Human factors that increase the use of these elements, which leads to an increase in these elements in the soil.

The method that been used in this research is an effective way to illustrate and evaluate the concentrations of heavy elements and their reasons. The focal points in the concentrations maps are exact because they are measured in the lab.

Abstract. This article reported investigations the effect of partial substitution potassium at calcium site for $HgBa_2Ca_2Cu_3O_{8+\delta}$ system with x from 0 to 0.2. All samples were prepared using solid state reaction technique. The samples were subjected to gross structural characterization by X-ray diffraction. The XRD data for the prepared samples are consistent with the Hg-1223 phases, and the analysis showed that the structures are tetragonal. Increasing potassium level results in decreasing the mass density (from 1.53 to 1.51), volume fraction (from 76.4 to 71.9), lattice parameters c, c/a length of c. Electrical resistance was testing by four-probe technique to determine the critical temperature, and it is noticed that the non-potassium $HgBa_2Ca_2Cu_3O_{8+\delta}$ compound has a critical temperature around 118 K, while introducing potassium in $HgBa_2Ca_{2-x}K_xCu_3O_{8+\delta}$ compound with x=0.1 and 0.2 led to decrease the critical temperature to 110 K and 93 K, respectively.

Keywords: partial substitution, Tetragonal structure, Potassium, Electrical Resistance, X-ray diffraction.

1. Introduction

The large variation in the layered structure of High Temperature Superconducting Compounds (HTSC) leads to important changes in physical, mechanical and structural properties such as magnetic field, electrical conductivity, current density, dielectric constant [1,4], hardness[5], tensile strength, elasticity, grain size and crystal size depending on the type of superconducting compound[6], the proportions of the elements and their partial substitution in the compound [4-8]. The difference in the stratigraphic composition of the high temperature superconducting compounds leads to important changes in the magnetic field depending on its movement that is relative to the axes of the crystal lattice. For superconducting planes, the direction of the magnetic field varies. The results of the measurements of the critical magnetic field and its critical temperature depend on the angle between the magnetic fields

and the surface (a – b). Generally, it showed that the dissipation in the electric magnetic field strongly decreases when the field tends towards the superconducting layers away from the c axis [9, 10]. Measurements in oblique fields were commonly analyzed in terms of the approach based on the anisotropic of mass. Anisotropy reduces the effective electric and magnetic field component in the same direction and parallel to the superconducting layers [11].The electric and magnetic field component along the c-axis is the only active component within highly anisotropic materials, because it has been found already experimentally at BSCCO system [4, 12]. For moderate contrast materials, such as Y-B-C-O, field scale has been shown to be valid in the flow region [13], and for Hg-Ba-Ca-Cu-O compounds families have anisotropy between those of YBCO and BSCCO. Regarding -2212 phase [14], only few investigations were reported on the angle dependence for the transmission characteristics. The resistance of (Hg, Re) $Ba_2CaCu_2O_6$ was recently studied under different directions of magnetic field with respect to c-axis, and the dependence of the dissipation field on the angle of inclination has been inferred [15]. The physical properties of many superconducting materials, such as high phase formation, temperature transition and the isolation of the superconducting compound Hg-1223 have been improved by means of cation substitutions and doping with highly valued pb, Re or other elements [16, 17]. The electrical resistance is one of the most important characteristics of material, and it is mostly a common method to determine the transition temperature of a superconductor.

The aim of this research is to study the effect of partial sedimentation of calcium with potassium, in $HgBa_2Ca_{2-x}K_xCu_3O_{8+\delta}$compound with different x values. Important measurements were carried out to determine the structural and electrical properties of the samples.

2. Experimental

The pure powders of HgO, CaO, CuO, BaO and K_2O_3 were weighted by a sensitive balance to form the chemical formula $HgBa_2Ca_{2-x}K_xCu_3O_{8+\delta}$, with x = 0, 0.1 and 0.2. The samples were synthesized by solid state reaction method. The chemical formulas listed below are the general guide for starting materials.

$HgO + 2BaO+(2-x)\ CaO + x\ K_2O_3+ 3CuO \rightarrow HgBa_2Ca_{2-x}K_xCu_3O_{8+\delta}$

The powders were mixed together using an agate mortar to produce a homogenous mixture, and the grinding process took a period of time between 30-50 minutes. The powders were shaped as a disc-pellets with a diameter of 15 mm and a thickness of 3 mm using a hydraulic press with 5 MPa pressure for 1 min. The pellets were pre-sintered at (850) $^{\circ}$C for one day using a Carbolite furnace with increasing the temperature rate by 7 ºC/min, then cooled down to 25°C with same heating rate. The crystal structures of $HgBa_2Ca_{2-x}K_xCu_3O_{8+\delta}$ compounds were obtained using X-Ray diffractometer type Shimadzu with the following features: Source: Cu K_α, Wavelength: 1.5405, Current: 30 mA, Voltage: 40 KV. The scanning speed is 8 degree/min in a 2θ range of (10-80) ^{o}. The computerized calculations for (a, b, and c) were based on Full Prof Suite toolbar [18]. The intensities of the X-ray diffraction peaks have been used in equation (1) to estimate the phase's volume fraction [19]:

$$V_{ph} = \frac{\sum I_O}{\sum I_O + \sum I_1 + \sum I_2 + \sum I_{other(peaks)}} \times 100\% \quad (1)$$

Where I_o= XRD phase peak intensity that determined, $I_1, I_2, \ldots I_n$ represented the peaks intensities of all XRD.

The densities (d_m) of the samples were determined using this equation [12].

$d_m = W_m / N_A V$..(2)

where: W_m= the molecular weight in (amu)

N_A=Avogadro's number (particles/gm ml)

V = the volume of the unit cell in (cm^3).

The superconductor's critical temperature was determined by measuring the electrical resistivity as a function of the temperature. Four-point probe technique was used to measure the electrical resistivity within a temperature range of (77-300 K).

The samples were tested under vacuum of 6 x 10^{-2} mbar prepared by a rotary pump. The cryostat was connected to the rotary pump, and a digital thermometer sensor was attached near the sample. Four copper wires were also connected to the sample through oven-dried silver paste, which served as two wires for the current and the others for the electric voltage. The sample was prepared with a current of 5 mA by means of a constant current source, and the voltage drop in the sample was measured using the nanometer as a function of its cooling. Resistivity (ρ) was measured as the temperature of the sample changed using the relationship:

$$\rho = \frac{V}{I}\frac{\omega t}{L} \qquad (2)$$

where: the current passing through the sample I, voltage drop between the electrodes V, ω is the sample width, L is the effective length passing through electrodes, and t is the sample thickness.

3. Result and Discussions

Figure 1shows the XRD pattern of $HgBa_2Ca_{2-x}K_xCu_3O_{8+\delta}$ compound with x=(0, 0.1, and 0.2). The figure illustrated that the potassium substitution has produced changing in the high (H-phase) and low phases (L-phase). It is also noted that the partial replacement leads to a displacement of the peaks and a change in their intensities, This confirms the interaction between the elements and components of the superconducting compound.

Table 1 shows the values of the crystal lattice constants and the mass density that calculated from the X-ray diffraction plot after applying Brack's law to each partial substitution value of x. This table shows that the mass density, lattice parameters, and volume fraction decrease with increasing potassium substitution. This is due to the substitution of calcium by potassium and the difference in the sizes of the atoms replaced the elements since the ionic radius of potassium is longer than that for calcium. This is because the expansion at the base structure of HgO results in decreasing in mass density, volume fraction, c/a and the length of c.

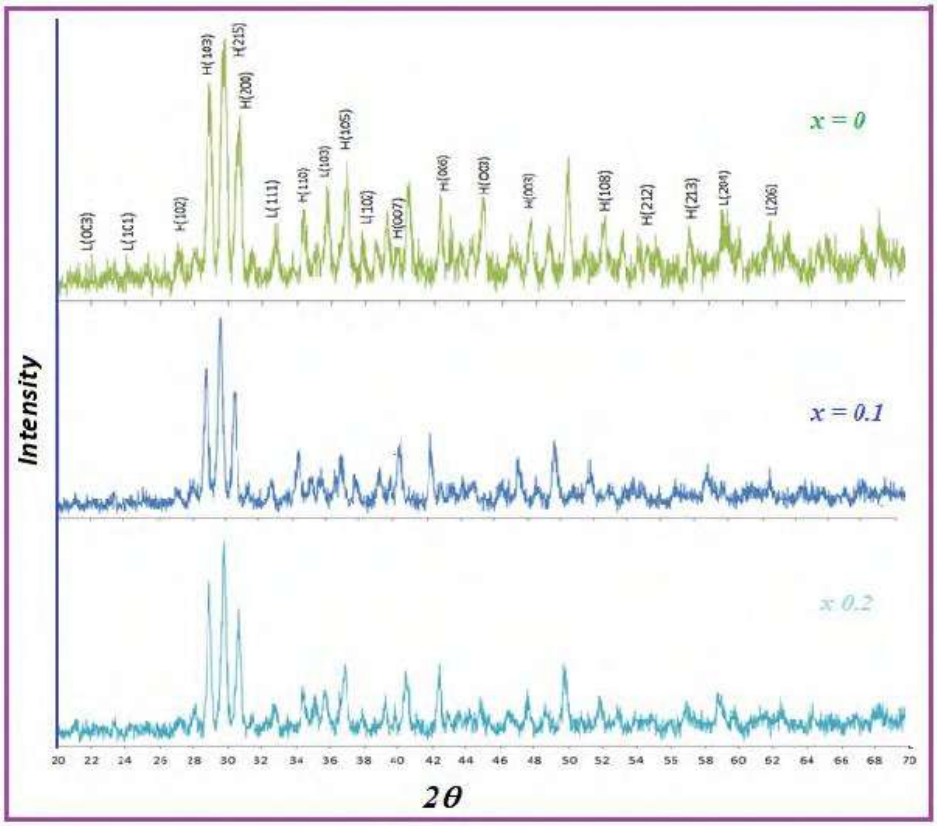

Figure 1. XRD of HgBa2Ca2-xKxCu3O8+δwith x=0, 0.1 and.2

Figure 2 illustrated the electrical resistivity as a function of the temperature for $HgBa_2Ca_2Cu_3O_{8+\delta}$, $HgBa_2Ca_{1.9}K_{0.1}Cu_3O_{8+\delta}$ and $HgBaCa_{1.8}K_{0.2}Cu_3O_{8+}$ compounds. n the first section, when the temperature drops from 300 to 155 K, it is noticed that the resistivity of the three samples behaves like a metal, but the temperature drops rapidly until it becomes zero, so we were able to determine two transition temperatures for each sample, which is $T_{c(onset)}$ and $T_{c(offset)}$. The transition temperature of pure curve was observed at 135 K ($T_{c(onset)}$) and at no-resistance. The ($Tc_{(offset)}$) were happened at 118 K, the transition range (ΔT) equal to 17K, while the values of transition temperatures for as grown $HgBa_2Ca_{1.9}K_{0.1}Cu_3O_{8+\delta}$ and $HgBaCa_{1.8}K_{0.2}Cu_3O_{8+\delta}$ (at zero resistance $T_{c(offset)}$) are 110 and 93 K, $T_{c(onset)}$ are 131 and113K, the change in transition width (ΔT=21and 10 k) respectively. This shows a decrease in the ΔT with increasing the Potassium concentration as shown in figure 3. Table 1 illustrated the decreasing in the mass density ρ_M and volume fraction with increasing potassium concentration.

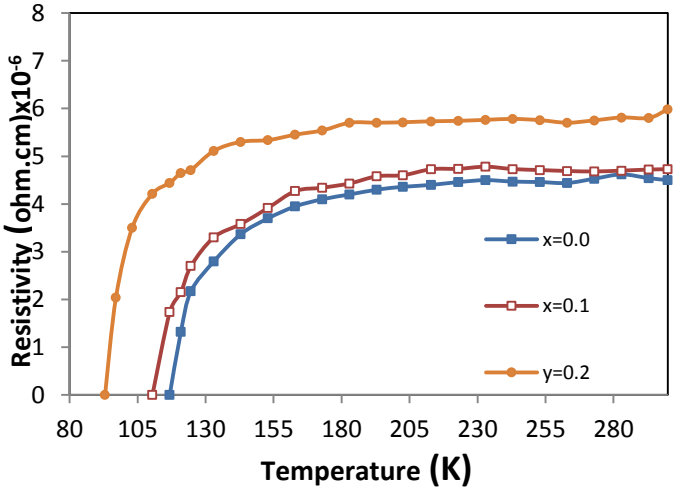

Figure 2. Temperature dependence of resistivity for HgBa2Ca2-xKxCu3O8+δ

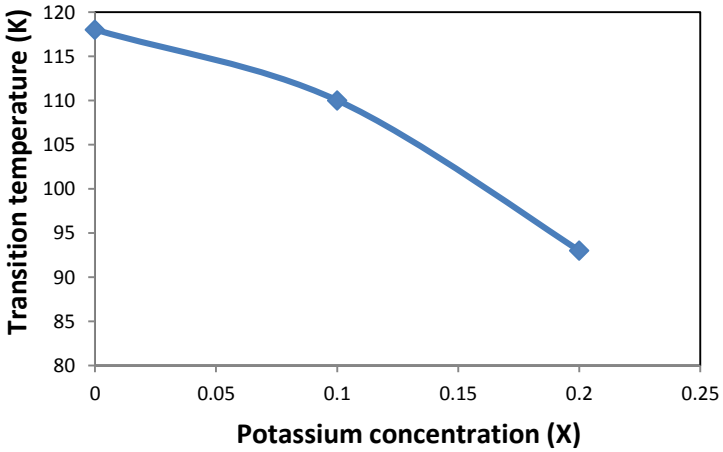

Figure 3. Temperature dependence of Potassium concentration for HgBa2Ca2-xKxCu3O8+δ

Table 1. Critical temperature Tc(OFF, ,Tc(ON), lattice parameters c, a, c/a, volume fraction and mass density for HgBa2Ca2-xKxCu3O8+δ system for x=0, 0.1 and 0.2.

X	$T_{c(OFF)}$(K)	$T_{c(ON)}$ (K)	$a(A^0)$	$c(A^0)$	c/a	ρ_M (g/cm^3)	$V_{Ph\text{-}1223}$%

0.0	118	135	3.845	15.78	4.099	1.53	76.4
0.1	110	131	3.833	15.37	4.006	1.52	74.4
0.2	93	113	3.846	15.36	3.999	1.51	71.9

4. Conclusions

In this study, we synthesized $HgBa_2Ca_{2-x}K_xCu_3O_{8+\delta}$ system with x=0, 0.1 and 0.2. The samples were prepared by solid state reaction process. The partial substitution of calcium with potassium in the Ca-O2 layer of $HgBa_2Ca_2Cu_3O_{8+\delta}$ has been studied with special emphasis on the effect of this partial substitution on superconductivity and microstructure properties. The XRD data collected from various samples show that all the samples are polycrystalline correspond to Hg-1223 phase. The critical transition temperature $T_{c(0ffset)}$ decreases from 118 to 93 when increasing potassium concentration. The results conclude that the substitutions of potassium lead to change in the volume fraction, lattice parameter and mass density.

Abstract. In this study, high quality ZnO/Ag-NPs thin transparent and conductive film coatings were fabricated *via* sol-gel process combined with spin-coating technique. Structural, surface morphology, electrical and optical properties were investigated by means of XRD, Hall effect measurements, FESEM and UV-Vis. The synthesized ZnO/Ag-NPs thin films shows a polycrystalline wurtzite structure, and the grain sizes enlarged when the annealing temperature increased. The surface morphologies of the coatings were dense, smooth and homogeneous as proved by FESEM images. The resistivity of (5.8×10^{-4} Ω.cm), the carrier concentration of (3×10^{20} cm^{-3}) and the mobility of (40 cm^2/V s) were obtained from the film post heated with 500 °C. Same thin film also shows the highest transmittance and energy gap of 88% and 3.71 eV respectively.

Keywords: ZnO, Transparent conductive coatings, Sol-gel, spin coating

1. Introduction

Over the past decades, optical transparency and electrical conductivity were considered inversely proportional. However, transparent and conductive materials (TCMs) have changed and wiped out this consideration through the exhibition of high optical transparency over the visible range of the light spectrum along with excellent electrical conductivity. Amongst these TCMs, transparent conductive oxides (TCOs) have been widely used in numerous optoelectronic devices including solar cells, light emitting diodes (LEDs), touch screens, displays, smart windows and sensors [1, 2]. Different materials were used as TCOs such as Indium oxide (In_2O_3) and tin-doped indium oxide known as indium tin oxide (ITO), zinc oxide (ZnO), aluminum and gallium doped ZnO (AZO, GZO), cadmium oxide (CdO) and tin oxide (SnO_2) [3, 4]. ZnO-based thin TCOs coatings have been widely used recently owing to its non-toxic, high stability and good optoelectronic properties. The TCOs based thin film coatings were produced so far *via* RF and DC sputtering, pulsed laser deposition, thermal evaporation, and sol-gel processes [5, 6]. The sol-gel is cheap, able to control the doping concentration, performed at low temperature and short time and produced coatings with preferred shape and surface area [7, 8]. ZnO can be doped with different elements including some transition metals such as aluminum (Al), silver (Ag), gallium (Ga), copper (Cu), indium (In), Titanium (Ti) etc. [9-11]. Combining silver nanoparticles (Ag-NPs) which have a reasonably good electrical conductivity and high optical transparency with ZnO has not been widely overlooked and discussed.

In this study, highly transparent and conductive system of ZnO/Ag-NPs was deposited on glass substrates by sol-gel spin-coating method. The thicknesses and the concentrations of both ZnO and Ag-NPs coatings were kept consistent throughout the sample fabrication process and the prepared thin films were post annealed at different annealing temperatures (300, 400 and 500) °C. Such kinds of bi-layer systems have not been extensively studied by researchers. The main goal of this investigation is to point out the role of Ag-NPs and annealing temperature on the structural surface topography, electrical and optical characteristics of ZnO coatings.

2. Methodology

2.1. Materials and methods

ZnO and Ag-NPs sols have been prepared using Zinc acetate dehydrate ($Zn(CH_3COO)_2.2H_2O$), purity 99.99%, Silver nitrate ($AgNO_3$, 99.5%), sodium borohydride ($NaBH_4$, 99.6%), 2-methoxy ethanol ($C_3H_8O_2$), purity 98%, mono ethanolamine (C_2H_7NO), purity 98% and polyvinylpyrrolidone (PVP, M = 40000g/mol). All the aforementioned chemicals were used without any purification.

A ZnO solution with 0.2 M was prepared by dissolving the appropriate amount of zinc acetate in 2-methoxy ethanol and stirring for 2 hours at 60 °C on a magnetic stirrer. The ethanolamine with a molar ratio of 1:1 was added to the resultant solution and stirred for another 2 hours at 60 °C.

The Ag nanoparticle solution was prepared with a concentration of 0.2 M. The required amount of silver nitrate was dissolved in 10 ml of de-ionized (DI) water. The concentration of $NaBH_4$ was kept consistent at 0.2 M in this work. In order to prepare the $NaBH_4$ solution, an adequate weight of sodium borohydride was dissolved and vigorously stirred in 50 ml DI water, and the obtained solution was chilled in an ice bath prior to the addition of $AgNO_3$ sol. The resultant mix was further stirred until a yellow solution was obtained.

The chemical reaction and reduction of $AgNO_3$ could be characterized by the following reactions [12, 13]

$$2AgNO_3 + 2NaBH_4 \rightarrow 2Ag + H_2 + B_2H_6 + 2NaNO_3 \quad (1)$$

$$AgNO_3 \rightarrow Ag^+ + NO_3^- \quad (2)$$

$$Ag^+ + e^- \rightarrow Ag \quad (3)$$

The ZnO/Ag-Nps thin film coatings were fabricated by depositing 50±5 nm Ag nanoparticles thin films onto 25×25 mm^2 dimensions glass substrates followed by pre-heat treatment at 150 °C for 1 hour. Then, 150±10 nm of ZnO thin film was deposited onto Ag-NPs thin films followed by pre-heating the resultant ZnO/Ag-NPs thin films at 150 °C for 1 hour. The spin-coating process for synthesizing ZnO/Ag-NPs thin films was performed at 3000 rpm for 30 seconds, and the resultant coatings were heat treated in air atmosphere at (300, 400 and 500) °C.

2.2. Characterization techniques

The crystallographic features of the ZnO/Ag-NPs films were characterized *via* (XRD) examination using a Siemens diffracto-meter with Cu-Kα source (λ=0.154nm). The surface topography was imaged using JEOL JSM-6301 (FESEM). The optical characteristics were carried out using UV-VIS spectrometer. The electrical properties were performed using a Dasol Eng. FPP-HS8 4-point probe, while the ECOPIA HMS-2000 instrument was used for Hall-effect measurements.

Scherrer relation was used to estimate the mean particle size of the synthesized ZnO/Ag-NPs thin films [14].

$$D = \frac{0.89\lambda}{\beta cos\theta} \quad (4)$$

where λ is the wavelength of X-ray beam, β is the line width at FWHM and θ is Bragg's diffraction angle.

The electrical resistivity (ρ) and conductivity (σ) are given by the following relations [15, 16]:

$$\rho = \frac{\pi}{ln(2)} t \left(\frac{V}{I}\right) \quad (5)$$

$$\sigma = N_e \times \mu \times e \quad (6)$$

where t is the film thickness, V is the voltage across the inner two probes and I is the current passed through the outer two probes, N_e is the carrier concentration, μ is the carrier mobility and e is the electron charge.

The free carrier mobility μ can be defined as:

$$\mu = \frac{e\tau}{m_e} \quad (7)$$

where m_e is the effective electron mass in the conduction band and τ is the average collision time of electrons.

The absorption coefficient (α) of the thin films can be calculated from the following equation [17]:

$$\alpha = \frac{1}{t} ln\left(\frac{1}{T}\right) \quad (8)$$

where t is the film thickness and T is the optical transmittance.

The transmittance and the absorption can be computed from the following equations [18]:

$$T = A \times exp\left(\frac{-4\pi kt}{\lambda}\right) \sim exp(-\alpha t) \quad (9)$$

$$A = \frac{16 n_\circ n_1 (n^2 + k^2)}{((n_\circ + n)^2 + k^2)+((n_1 + n)^2 + k^2)} \quad (10)$$

where n_o, n and n_1 are the refractive indices of air, film and substrate, respectively and k is the extinction coefficient.

The band gap energies (E_g) for the prepared thin films were estimated using the formula [18]:

$$(\alpha hv)^2 = A(hv - E_g) \quad (11)$$

where α is the absorption coefficient, hv photon energy, A constant represents the proportionality coefficient, E_g the energy band gap and $n = 1/2$ for allowed direct transitions.

3. Results and discussions

3.1. Descriptions of Ag-NPs colloidal solution

The mechanism of reduction Ag ions by $NaBH_4$ to form Ag nanoparticles follows three main steps. Once the solutions mixed, the first step starts, and the tiny particles of 3 nm were grown. As the reaction continues (the second step), the Ag particles further grow within a period of (20 – 60 min) reaching (8 – 20 nm). In the final step, all the $NaBH_4^-$ is used. Accordingly, the stabilizing BH_4^- is consumed, and the solution changed from reducing state to the oxidizing state [19]. Both the modifications of the surface potential of Ag particles and the adsorption of BH_4^- promote the agglomeration of Ag-NPs.

The distinctive colours of Ag-NPs solution are mainly assigned to the plasmon absorbance, especially when the incident light promotes the vibrations of the electrons at Ag-NPs surfaces subsequently, the light is absorbed [20, 21]. From figure 1, the absorption peak of Ag-NPs solution was located at 405 nm. It has been evident that the shape and the position of the absorption peak of metal-NPs depend on the particle size and the dielectric medium [22]. Also, Van Hyning *et al.* stated that the maximum of the plasmon absorption peak for Ag-NPs solution at 405 nm wavelength is attributed to the formation of a grain size of (10 – 14) nm [19].

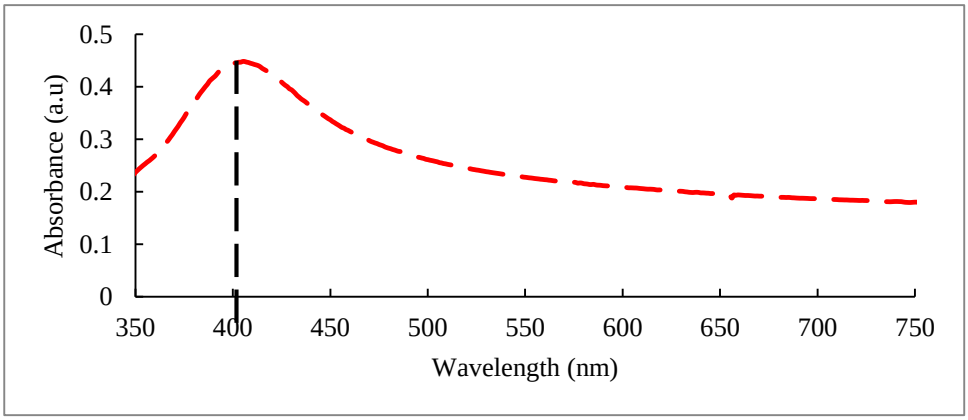

Figure 1. Absorption spectrum of prepared Ag-NPs solution

3.2. Crystalline structures

Figure 2 shows the XRD outlines of ZnO/Ag-NPs thin films post annealed at different temperatures. From figure 2, synthesized films exhibited polycrystalline feature with sharp and intense peaks correspond to the wurtzite structure of ZnO as expected and *P63mc* space group (JCPDS card 070-8070) [23]. The peaks of ZnO/Ag-NPs coatings observed at 2θ values of 31°, 34°, 36°, 47°, 56° and 63° are linked to (100), (002), (101), (102), (110) and (103) reflection orientations respectively. This may be attributed to the early coalescence of the Ag-NPs coating that facilitates the growing of high quality top ZnO layer, and reduces the effect of the thermal expansion mismatch between the glass and the ZnO film. With increasing the calcination temperature, the polycrystalline structures for all the synthesized thin films were improved, and the film treated with 500 °C shows the most intense peak as seen in figure 2. This is because at high temperature the ZnO particles supplied with a sufficient energy to accumulate at the preferred (002) orientation. Also, high annealing temperature assists the diffusion and the accumulation of Ag-NPs within the ZnO matrix by increasing the thermal energies of these particles and/or substituting of the Zn atoms in their sites by Ag atoms. It has been reported by Cao and co-workers [24] that the energetic particles in a crystalline structure tend to gathering and accumulating along the preferred orientation plane lead to improve the crystalline quality.

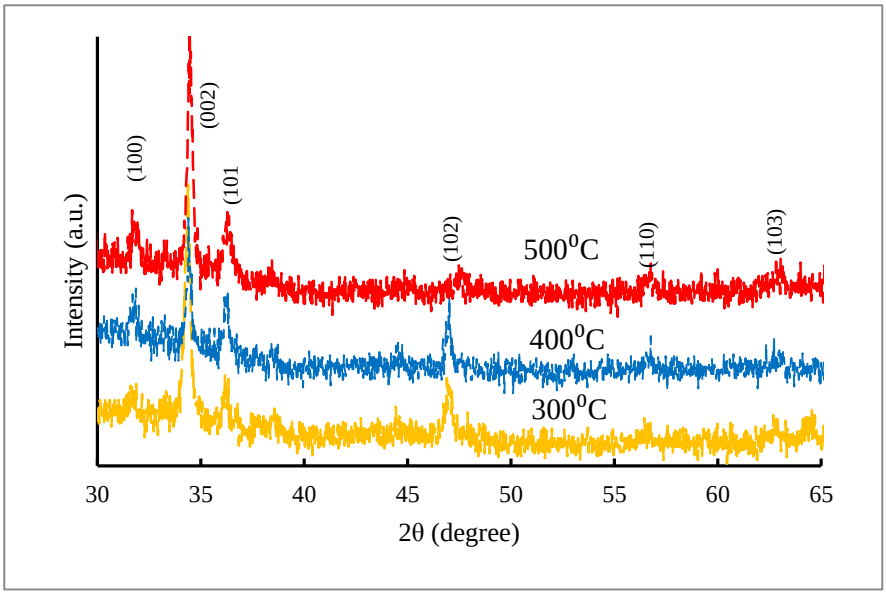

Figure 2. XRD patterns of post annealed ZnO/Ag-NPs thin films

Scherrer relation (Eq. 4) was used to estimate the mean particle size of the synthesized ZnO/Ag-NPs thin films.

The grain size of ZnO/Ag-NPs coatings is enlarged with increasing the calcination temperature and the highest value of *D* was found to be 45 nm for the film annealed at 500°C due to enhance the substitution of Zn by Ag ions, and the agglomeration of the Ag particles in the grain boundaries of ZnO matrix which lead to decrease the density of the grain boundaries and hence improve the crystalline quality. Liu and co-authors [25] have been reported the same tendency of enlarging the crystallite size of both Ag-NPs and ZnO thin film and they stated that the crystalline structure of ZnO thin film did not changed with introducing Ag-NPs to the film material.

3.3. Surface morphology

Figure 3 shows the FESEM images of annealed ZnO/Ag-NPs thin films. All the fabricated coatings exhibited uniform, smooth, dense and homogenous surfaces confirming the growing of a crystalline feature of ZnO. This could be attributed to the formation of continuous Ag-NPs coating underneath the ZnO coating which assists the growing of homogenous and free pinholes surface morphology for ZnO coating. Also, high annealing temperature results in improving the surface morphology along with increasing the grain sizes of the fabricated ZnO-based thin films.

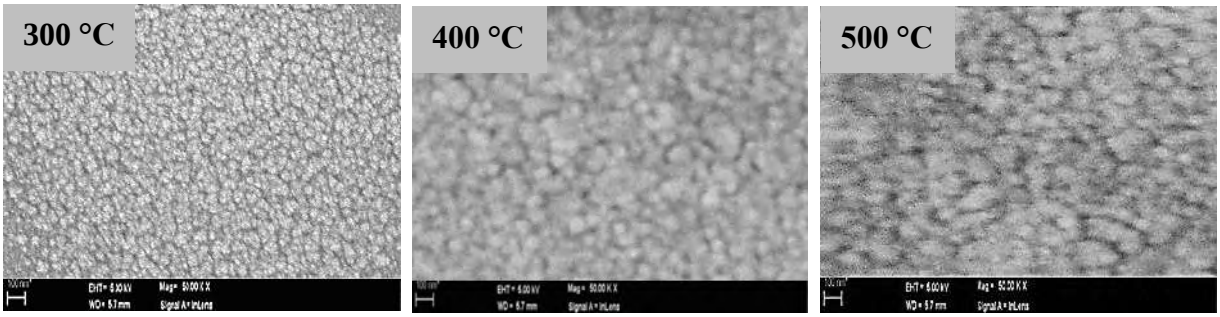

Figure 3. FESEM images for post annealed Ag-NPs thin films

3.4. Electrical properties

Figure 4 (a and b) displays the variations of the resistivity, conductivity, carrier concentration and mobility of annealed ZnO/Ag-NPs thin films with annealing temperature. In general, the average resistivity of the ZnO/Ag-NPs thin films is low enough comparable to those for ITO-based thin films in our previous study [26]. This confirms that ZnO-based thin transparent and conductive coatings can be good choice to substitute the expensive ITO material. With increasing annealing temperature from 300 °C to 500 °C, the resistivity is reduced from 7.8 $\times 10^{-4}$ Ω.cm to 5.8 $\times 10^{-4}$ Ω.cm while the conductivity is improved from 1282 $S.cm^{-1}$ to 1724 $S.cm^{-1}$. Moreover, the carrier concentration and the mobility of the synthesized ZnO/Ag-NPs thin films are also improved and the highest values of the carrier concentration (~ 3×10^{20} $cm^{-}3$) and mobility (~ 40 cm^2/Vs) were obtained for the film annealed at 500 °C. This could be assigned to the role of annealing temperature that assists the diffusion of Ag atoms through ZnO matrix either to substitute Zn atoms on their sites (as discussed previously) or to occupy random sites and growing as coalescences of Ag particles and hence forming effective conducting paths for the charge carriers. It has been reported that the free electrons prefer to transport through these conducting paths rather than ZnO matrix, and these paths also enhance the carrier mobility of the thin film [27]. Furthermore, annealing temperature results in enhancing the crystalline structure and enlarging the grain size of fabricated thin films as proved in the XRD analysis. Accordingly, the density of grain boundaries reduced and the chained electrons liberated thus the number of the charge carriers in the thin film matrix increased.

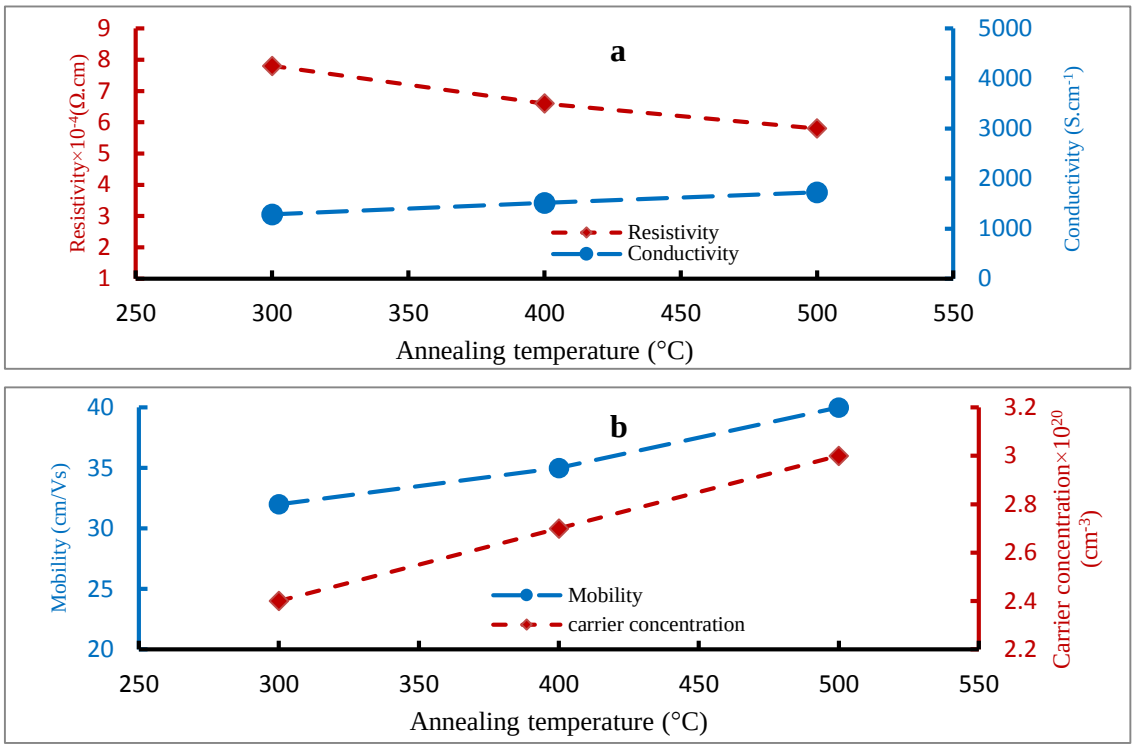

Figure 4. Variations of the electrical properties of Ag-NPs coatings with annealing temperature

3.5. Optical properties

Figure 5 (a and b) displays the transmittance spectra and the variation of the optical band gap energy of ZnO/Ag-NPs thin films. The optical transmittance of all the thin films strongly depends on the annealing temperature and it is increased from 85 % to 88% after increasing the annealing temperature from 300 °C to 500°C. This can be attributed to the high uniformity of both the ZnO top layer and the Ag-NPs bottom layer, as well as the low density of the scattering centres along with low absorption of incident photons. In addition, increasing annealing temperature enhances growing of continuous thin film coatings. Despite the obtained optical transparency of ZnO/Ag-NPs thin films in this investigation is poorer than that obtained for ITO-based thin films in our previous study [28], it stills considered adequate for optoelectronic devices.

The calculated energy band gaps of annealed ZnO/Ag-NPs thin films are presented in figure 5b. The results show that the ZnO/Ag-NPs thin films have high energy band gap values indicating a band gap broadening takes place. This is an expected behaviour due to higher optical transmittance of the ZnO/Ag-NPs thin films. Also, widening the energy band gap could be linked to the enhancement of the crystallographic features of ZnO/Ag-NPs films and enlarging the grain size along with increasing annealing temperature onto deposited thin films. The E_g for annealed ZnO/Ag-NPs thin film was increased from 3.68 eV to 3.71 eV when the annealing temperature increased from 300 °C to 500°C. This could be attributed to improving the crystalline quality through enlarging the crystallite size and

reducing the density of grain boundaries in the thin film matrix owing to increasing the annealing temperature. [28].

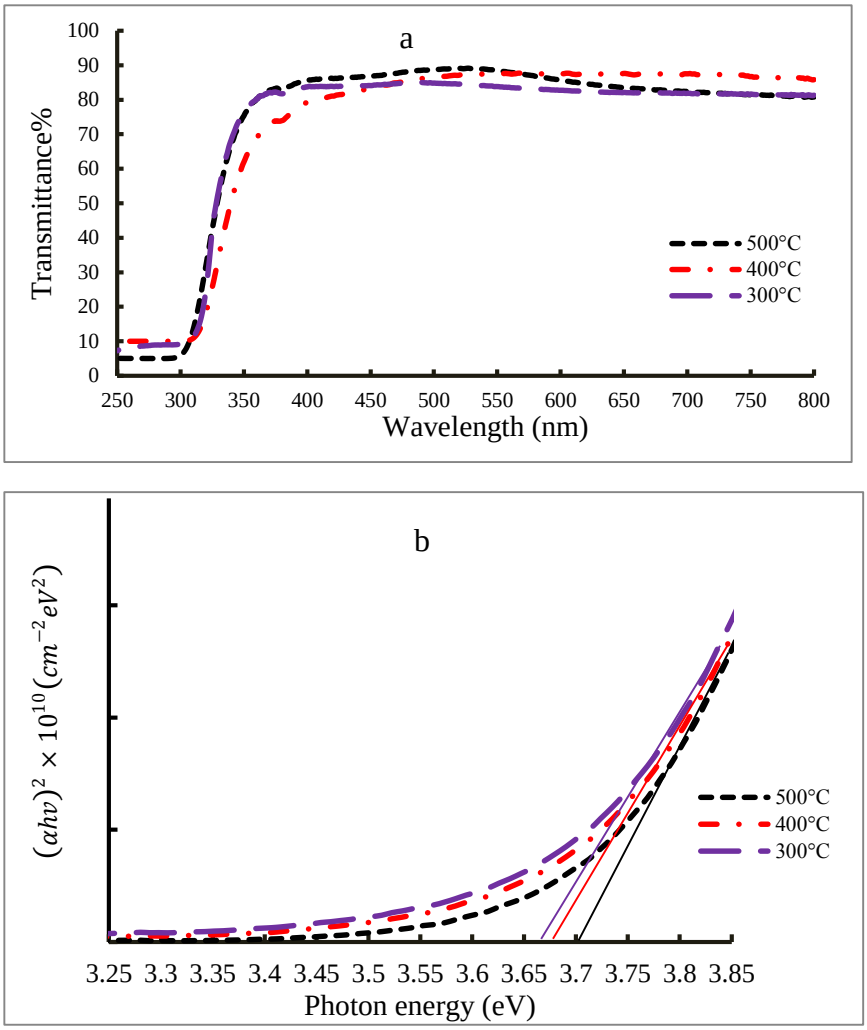

Figure 5. a- Transmittance and b- energy gaps of annealed ZnO/Ag-NPs thin

4. Conclusions

ZnO/Ag-NPs thin transparent conducting oxide coatings were successfully fabricated *via* a sol-gel spin-coating technique. The effects of annealing temperature on the structural, surface morphology, electrical and optical properties of these thin films were investigated. Combining Ag-NPs layer underneath ZnO layer did not affected the ZnO structure. The grain of these coatings is enlarged with further annealing, and the highest value was obtained for the film annealed at 500 °C. FESEM images show that all the thin films display uniform, smooth, dense and homogenous surface with a grain feature indicating a polycrystalline structure of ZnO phases. The electrical resistivity of the prepared thin films was dropped along with increasing annealing temperature achieving the lowest values of 5.8×10^{-4} Ω.cm. The maximum optical transparency in the visible region and the largest E_g were 88% and 3.71 eV respectively.

The structural properties and Energy Gap of PVDF/LiAlO2 Nanocomposite Thin Films

The structural properties and Energy Gap of PVDF/LiAlO2 Nanocomposite Thin Films

Ruqaya Fouad Kadhim and Zainab Raheem Muslim

University of Baghdad, College of Science, Physics Department

Ruqia.f.k@gmail.com

Abstract. lithium aluminate (LAO), $LiAlO_2$ powders were synthesized by sol-gel method because it was developed for preparing nano-sized at low temperature.The X-ray diffraction (XRD) found out a tetragonal structure for $LiAlO_2$. Various percentages of 1, 2, 3 and 4 wt. were applied to the LAO with polyvinylidene fluoride (PVDF) polymer. The obtained materials were characterized by Atomic Force Microscopy (AFM) and Field Emission Scanning Electron Microscope (FESEM). Structural analysis indicates the presence of polycrystalline phase with nanometre scale. Energy gap were studied and the results shows a decrease in energy gap with the increasing in weight ratio of LAO. This decline in the value of optical energy is due to an increase in the density of the band-gap of localized states.

Keyword: PVDF, $LiAlO_2$, polymer, energy gap

1. Introduction

In high energy density states, the increasing interest in solid batteries is leading many researchers to explore new concepts and related materials. The lithium-ion technology that uses polymer electrolytes as a separator for rechargeable batteries tends to provide the most promising choices[1]. Recently, there has been considerable interest in Al-doping ($LiMO_2$, where M is a transition metal) of lithium intercalation oxides. Theoretically and experimentally, Al transition-metal cation replacement has been shown to increase the cell voltage. Some of Al 's benefits are that it is light, cheap, and non-toxic [2].

Lithium aluminate ($LiAlO_2$) can be used as the best ceramic fillers for polymer electrolytes, and it is primarily used as a possible economical lithium battery cathode in the energy industry in nuclear physics and solid chemistry. $LiAlO_2$ normally crystallizes at ambient conditions, called γ-phase, in a tetragonal structure. Then, in the past few decades, several interesting phases of $LiAlO_2$ have been discovered or synthesized. A low temperature step with orthorhombic symmetry was defined as β-$LiAlO_2$[3]. Lithium aluminate synthesis has essentially been carried out by many methods: sol-gel, solid state, wet chemical, using templates, different precursors and combustion processes [4]. A graphite anode, a lithium-metal oxide cathode, an electrolyte solution containing lithium salts, and a polymeric separator typically consist of a lithium-ion battery [5].

Indeed, for electronic charges, the separator should be electrically insulated and at the same time sufficiently porous to ensure electrolyte uptake to enable ionic conductivity. A necessary requirement for the functioning of the battery is high ionic conductivity. In addition, the high dimensional stability,

as well as good mechanical properties of the polymeric separator at high temperatures is important to avoid a short circuit between the cathode and the anode, which can probably result in a failure of the battery. Several materials such as gel-forming polymers and polymeric separators have been investigated in the literature, such as polyvinylidene fluoride (PVDF), polyethylene oxide (PEO), polypropylene (PP), polyethylene (PE), and copolymers of the latter. PVDF separators obtained by phase inversion methods are used by most batteries on the market today [6].

Metal oxide nanoparticles applied to the polymer material will make a major contribution to the internal components of the battery in terms of electrical conductivity as well as mechanical strength and greater thermal stability thereby contributing to improving the protection of the cell [7,8]. Because of its characteristics, such as the ability to boost lithium ion transfer and electrolyte absorption, nano-silica is one of the most investigated fillers, thus increasing mechanical strength, electrode interface stability, and ion conductivity [9].

A. M. and P. Indolia. S. Gaur (2013) studied the optical characteristics of PVDF-ZnO thin films. This study showed that the optical properties of nanocomposite thin films depends on the ZnO contents and have the best optical properties [10].

The goal of this work is to explore the impact of LAO material on PVDF pristine and PVDF: LAO nanocomposites with different concentrations of LAO optically. The key focus of the present analysis is on the optical band difference of different percentages of PVDF and PVDF:LAO.

2. Experimental part

2.1 Preparation of lithium aluminate$LiAlO_2$

The $LiAlO_2$ powder synthesis was processed by the chemical method of Sol-gel. First, the mixture was dissolved in (50 ml) using equal quantities of Li and Al nitrates with citric acid (1:1:2) and combined with distilled water, and left to evaporate for 1 day at 70 ° C until gelled, then heat-treated for two hours at 650 ° C. The powder prepared by sol-gel shows a sponge with a color of white. The stage of heating in the 150 °C, LAO shows a sponge porous structure before the calcination process, these processes may be considered to have a fine and crystalline powder. The calcination temperature (650) °C was proper to get nanosized particles, followed by grinding process to reduce the coarser particles using a large in crucible like container. The resulting prepared powder color was white. Using hot process casting of these composites, this method decreases the prosily-due compacting, which increases composition conductivity in order to decrease volume and improve lithium ion mobility by offering the conductivity direction along with the structure.

2.2 Preparation of PVDF: LAO nanocomposites

The developed nanocomposites were prepared using the method of phase inversion. The casting solution was composed of PVDF powder dissolved in N, Ndimethylformamide (DMF) and various modified LAO concentrations. LAO in the ratio (1, 2, 3, and 4 % wt.) was applied to all the components and combined by stirring to prepare the casting solution for at least 5 hours. By means of a hand-casting knife, the solutions were uniformly cast on a glass substrate and then immersed in a coagulation bath after exposure to the air for a fixed period (one day). To ensure that the excess solvent was extracted, the flat-sheet thin film was kept in the water bath for at least 1 day.

3. Results and discussions

3.1 X-ray diffraction analysis

The X-ray diffraction spectra for lithium aluminate $LiAlO_2$ (LAO) synthesis by sol-gel method are reported in Figure 1. The X-ray spectra indicates the formation of tetragonal structure $LiAlO_2$ with card No.(JCPDSNO.) 96-100-8167, and the secondary phase Al_2O_3 has orthogonal structure with card No. (JCPDS 96-100-0443).

The main peaks at 22.25°, 24.3°, 28.19°, 33.35°, 34.63°, 50.12°, 56.25°, 61.34°, 72.44°, and 78.41° corresponding to (101), (110), (111), (012), (200), (220) (130), (302) (332), and (330) indicates the

formation of pure $LiAlO_2$, Some extra secondary peaks (secondary phases of Al_2O_3) are seen adjacent to the peak features and may be due to the presence of the impurity process. In Table 1, the structural properties are explained as full width at half maximum (FWHM), index plane, and grain size that agree with [11,12].

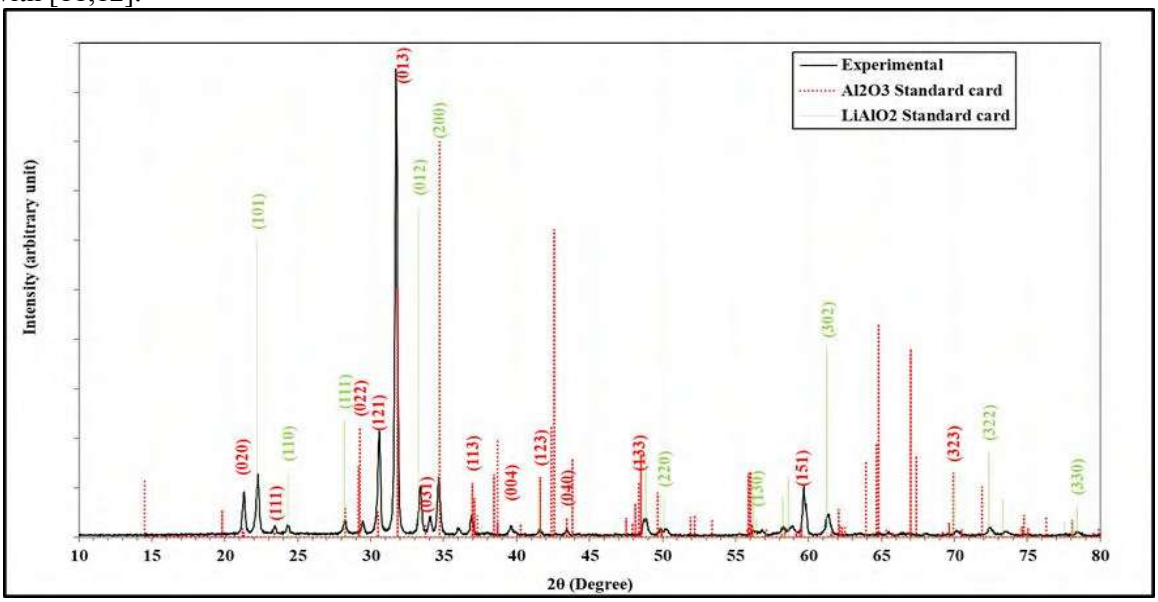

Figure 1. X-ray diffraction spectra of $LiAlO_2$.

3.2 Atomic force microscopy for $LiAlO_2$ powder

Atomic force microscopy (AFM) was performed to measure the average diameter and the grain size for the samples in the shape of a pellet by using AA3000 scanning probe Microscopy by Angstrom Advanced Inc (USA). The AFM pictures morphology for the surface of the $LiAlO_2$ NPs in the two and three dimensions are shown in Figure 2a and b. The pictures are shown a uniform surface; indicate that the particle has uniform dimensions.

The average diameter on the surface is found by granularity cumulating distribution chart to be 82.65 nm for $LiAlO_2$ as shown in Figure 2c.

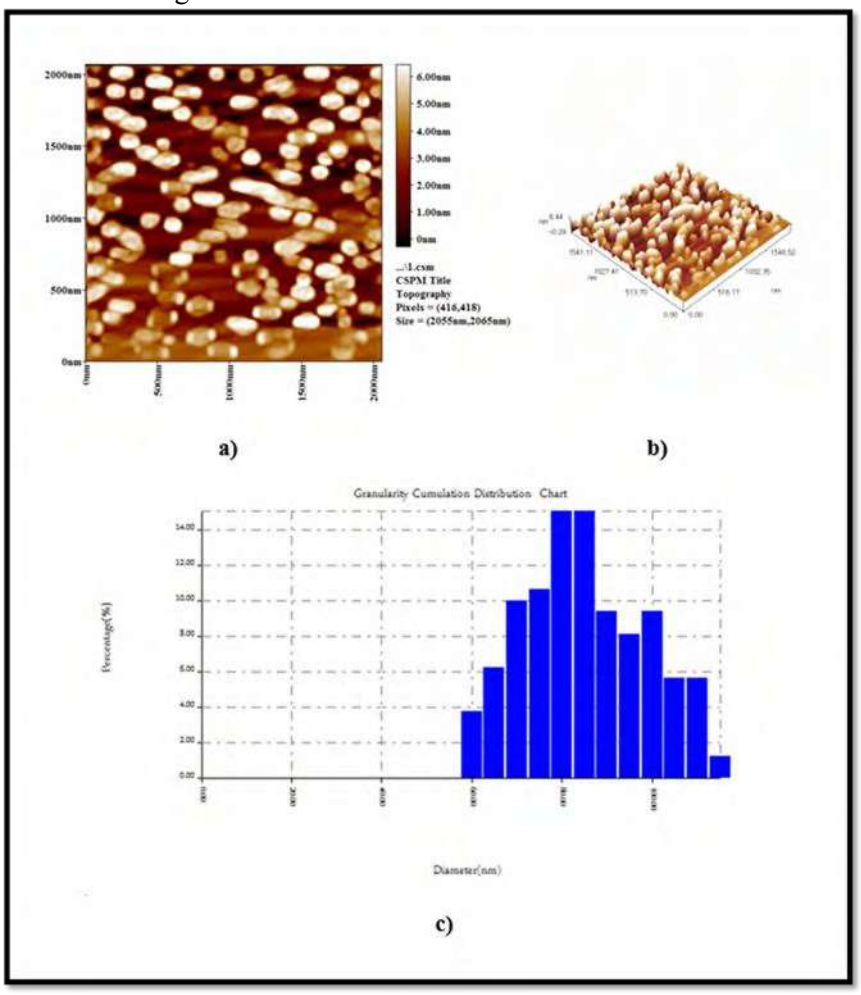

Figure 2. AFM micrograph for $LiAlO_2$ were (a) 2D, (b) 3D and (c) Granularity cumulation distribution chart.

3.3 Field Emission Scanning Electron Microscope (FE-SEM)

Typical sample findings from the field emission scanning electron microscope (FE-SEM) are shown in Figure 3. PVDF pure and PVDF: $LiAlO_2$ 1% thin film FE-SEM picture demonstrates that the sample consists of large agglomerated clusters. It can be seen under high magnification that each cluster consists

of multiple spherical nanoparticles, each of which has a smooth surface. The addition of LAO to the PVDF has a significant impact on the morphology of the film. As the content of LAO increased, the size and density of the pores increased.
In Figure 3a, the film is relatively smooth and flat with small and few pores. More bigger pores were formed when 1% LAO was added into the PVDF solution, as shown in Figure 3b.

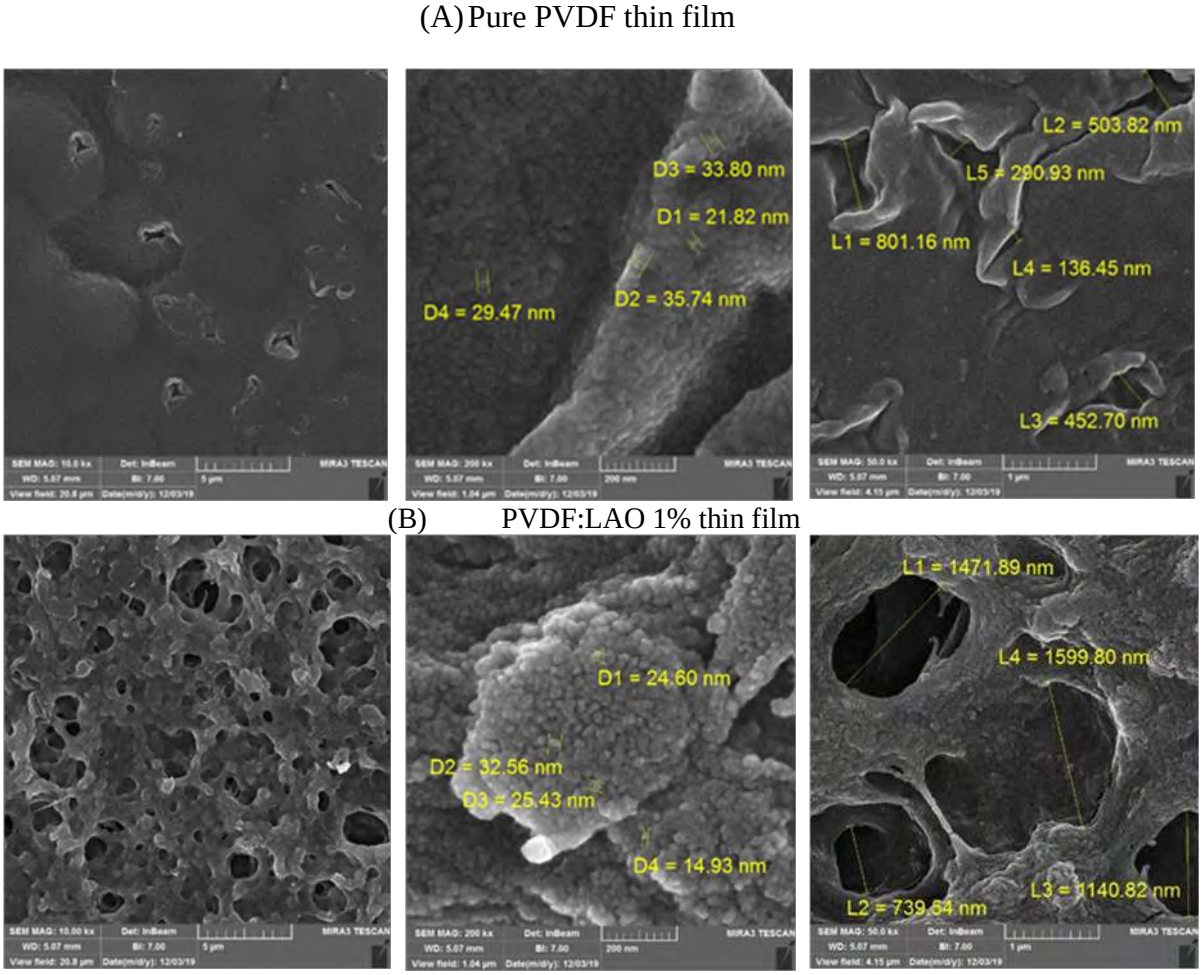

Figure 3. SEM images of (a) pure PVDF and (b) PVDF : $LiAlO_2$ 1% thin film.

3.4 Optical band gap
For pristine PVDF and PVDF: LAO composite films, the optical band gap can be obtained by taking into account the linear portion of the UV-Visible spectrum at the absorption edge. It is obvious from Figures 4 and 5 that all samples display absorption edges that are red-shifted with LAO nanoparticles.
Figure 4, 5 and Table 2 are shown the energy gap variation with Various LAO proportions (1, 2, 3, and 4 % wt.) nano-powder. The results show a decrease in the energy gap(direct band gap) due to an increased in inter atomic spacing which decrease the potential, this inturn reduce the energy band gap.
Tauc plots identified direct PVDF:LAO band gaps in nanocomposite films:

$$f(h\upsilon) = (\alpha h\upsilon)^2$$

Where α is the absorption coefficient which was determined by the following expression:

$$\alpha(\upsilon) = 2.303(\frac{A}{t})$$

When A is the optical absorbance, and t is the thickness of the polymer nanocomposite thin film and it is approximately equal to 3.5mm.

Doping may affect the optical band gap; the low energy gap was due to high density of localized state. Impurities are the increase in doping due to dopants, as the chemical composition changes during doping. A shift in the energy distribution of the permissible states cannot have a general rule such as after impurities are added, the band gap will decrease [10].

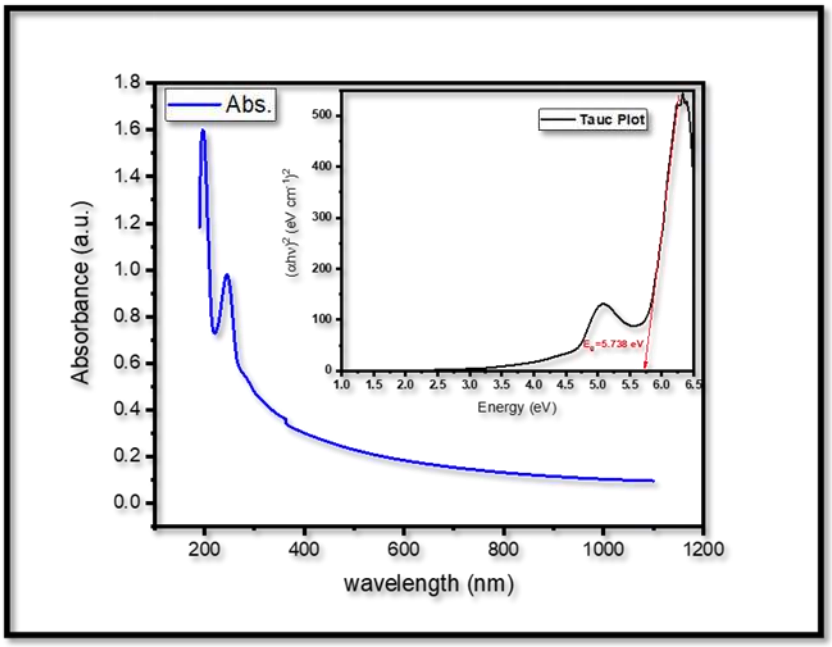

Figure 4. Energy gap of pure PVDF thin film.

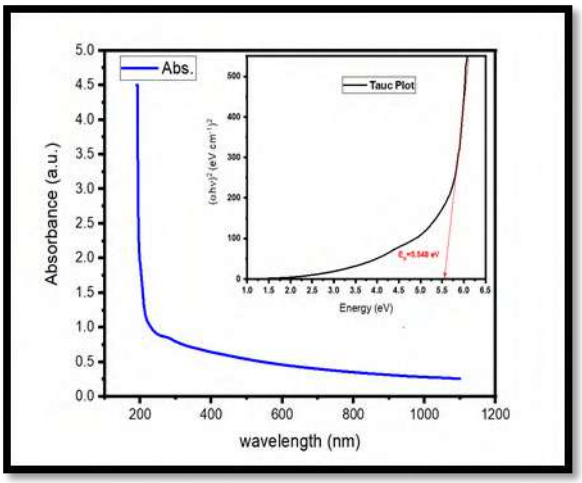
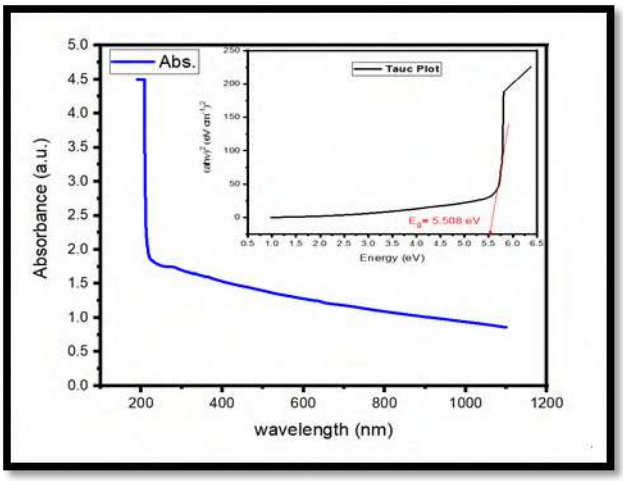
Table 2. The Energy gap of PVDF:LAO thin film.

Sample		Energy gap (eV)
PVDF		5.73
PVDF:LAO	1 %	5.54
	2 %	*5.50*
	3 %	5.45
	4 %	*5.33*

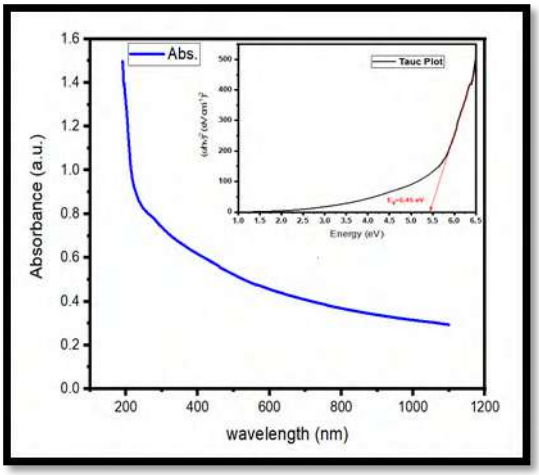
The band-gap is a non-approved energy zone. The density of states versus energy depends on the substance's chemical composition; if the chemical composition is changed, at least, in principle, the state density distribution should change. Dopants are impurities, because, by doping, the chemical composition changes. A change in the energy distribution of the permissible states cannot have a general rule such as: after the introduction of impurities, the band-gap would decrease. Generally, these



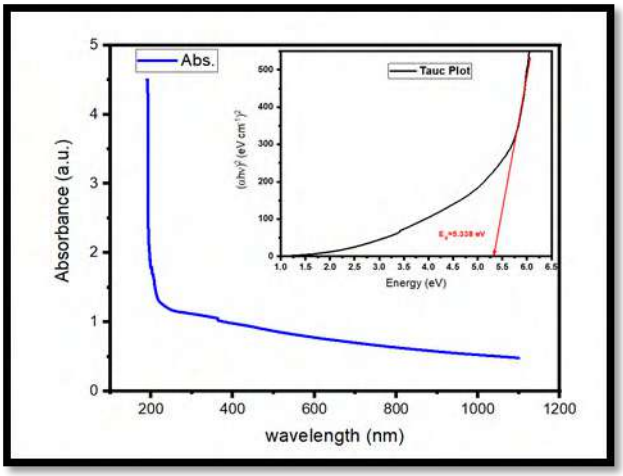
PVDF:LAO 1%



PVDF:LAO 2%



PVDF:LAO 3%



PVDF:LAO 4%

Figure 5. Energy gap of PVDF:$LiAlO_2$ thin film.

impurities are called dopants, which in the band-gap produce permissible shallow states. Shallow states have small energies of ionization; and when the doping density is high, a band is formed by dopant states. If the valence or conduction band edge is very close to this band, the band gap will decrease [10].

4. Conclusion

Lithium Aluminate ($LiAlO_2$) has been successfully prepared using sol-gel. The dependency of the optical properties of nanocomposites on $LiAlO_2$ material has been investigated. As the content of $LiAlO_2$ increases, the optical band gap for this process for direct transitions decreases. The structural changes

that occur after adding $LiAlO_2$ nanoparticles may be correlated with this activity. Due to the inclusion of $LiAlO_2$ nanoparticles, there is a drop in the optical energy gap of nanocomposites. The decrease in the optical distance indicated by the energy of optical activation can be associated with a decrease in network disorder.

Abstract. In this article, internal CRn measure have been carried out in twenty-three locations various rooms and Laboratory of Department Physics in science college in the university of Mustansiriyah. CRn were measure by Rad-7 detector. The results show that, the maximum CRn in indoor rooms was found in Electronics Laboratory (64.9 Bq/m3), whilst the minimum CRn was found in room rapporteur of higher studies (2) / Department of Physics (24.3 Bq/m3), which was lower (200-300Bq/m3) indoor air and the value of parameters hazard indices were lower than the value of permissibility limit.

Keywords: C_{Rn}, Science College, Rad-7, Laboratory.

1. Introduction

The exposure of 222Rn and the radioactive progeny present in the environment outcomes in big contribution to the rate effective dose received by the human beings [1,2]. The natural of 222Rn and it is airborne progeny can cause a significant indoor health hazard ,especially when they build up in enclosed regions, like educational laboratories in universities, caves and mines. The implementation of EURATOM directives [3] creates new scenarios in the radioactivity natural field, regarding 222Rn gas measurements in workplaces. Workplaces may differ from dwellings in terms of the structure building, microclimatic conditions, and occupancy factors. Some of workplaces of peculiarities are:(a) presence of forced ventilation or air conditioning(b) multi storeyed buildings with biger entrance hall (c) high probability of levels of humidity and finding elevated temperatures, dust and aerosols(d) widespread use of the basements or ground floor.

2. Detector technology

The interior detector of Rad-7(Serial Number 2764) is cell of the hemisphere with the volume approximately 0.72 L. The 222Rn gas and daughters, deposited on the detector surface and when decay, they emit alpha particles of special energy directly into the middle. Rad -7 detector draws air from the environment through desiccant and inlet the filter for the measure chamber.[4]. The detector of Rad-7 was related with tubing and the desiccant to soak up humidity, see in fig. (1).

Figure (2) shows RAD-7 electron- ic continuous radon monitor. Sniff mode and circle time was set to be 1 hour in accordance with running time of each path of the valve. To investigate radon released from the sample to air, the sample was enclosed into a column and airborne radon was measured with a continuous monitor of electrostatic type (RAD-7, Durridge company, USA).

Figure (2) shows RAD-7 electronic continuous radon monitor. Sniff mode and circle time was set to be 1 hour in accordance with running time of each path of the valve. In order to investigate radon released from the sample to air, the sample was enclosed into a column and airborne radon was measured with a continuous monitor of electrostatic type (RAD-7, Durridge company, USA).

3. Measurements of hazard indices:

Potential Alpha Energy conce. (PAEC) = $(C_{Rn} / 3700) \times (f)$ [1]
Where :C_{Rn} (^{222}Rn gas conce. in Bq.m^{-3}unit) , (f = 0.4) [6].
Exposure to ^{222}Rn progeny (E_P) = PAEC×8760 × n × 170 [2]
n= (0.8),(8760) is number of hours per one year,170 is number of hours per working month
annual effective dose (AED) = h × t × D × C_{Rn} × f [8]
(D) = [9×10^{-6} (m Sv)/(Bq. m^{-3}.h)] , f =(0.4), (h) = (0.8), t=(8760 h/y).
lung cancer cases per year per million person (CPPP)=(18×10^{-6} mSv^{-1}.y)×AED [3]

4. Outcomes and debate

Indoor C_{Rn}, were measurement in various compartments for twenty-three various rooms or Laboratory of Department Physics in science college in the university of Mustansiriyah , Table (1) summarize the C_{Rn} in indoor rooms .From Table (1) it can note that, the maximum C_{Rn} in indoor rooms was found in Electronics Laboratory (64.9 Bq/m^3),whilst the minimum C_{Rn} was found in room rapporteur of higher studies(2) / Department of Physics (24.3 Bq/m^3), see Fig. (3), with rate value (38.6±6.9), that is lower than the extent (200-300Bq/m^3) [9], however, the minimum value for indoor C_{Rn} due to very good ventilation conditions of rooms or Laboratory.

The maximum (PAEC) was found in Electronics Laboratory which was (0.007 mWL), whilst the minimum (PAEC) was found in room rapporteur of higher studies (2) / Department of Physics (0.0026 mWL) with rate value (0.0042±0.001mWL), that is lower than the value (53.33 mWL) [10].

The maximum (E_P) was found in Electronics Laboratory (8.36 $mWLMY^{-1}$), whilst the minimum (E_P) was found in room rapporteur of higher studies (2) / Department of Physics (3.13 $mWLMY^{-1}$), with rate value (4.97±0.9$mWLMY^{-1}$), that is lower than the extent (1-2 $WLMY^{-1}$) [6].

The maximum (AED) was found in Electronics Laboratory (1637.3 mSv/y), whilst the minimum (AED) was found in room rapporteur of higher studies (2) / Department of Physics (613.06 mSv/y) ,with rate value (973.83±0.9 mSv/y) , that is lower than the extent (3-10mSv/y) [11].

The maximum (CPPP) was found in Electronics Laboratory (29.47), whilst the minimum (CPPP) was found in room rapporteur of higher studies (2) / Department of Physics (11.04), with the rate value (17.53±3.1) , that is lower than the extent (170-230) [11].

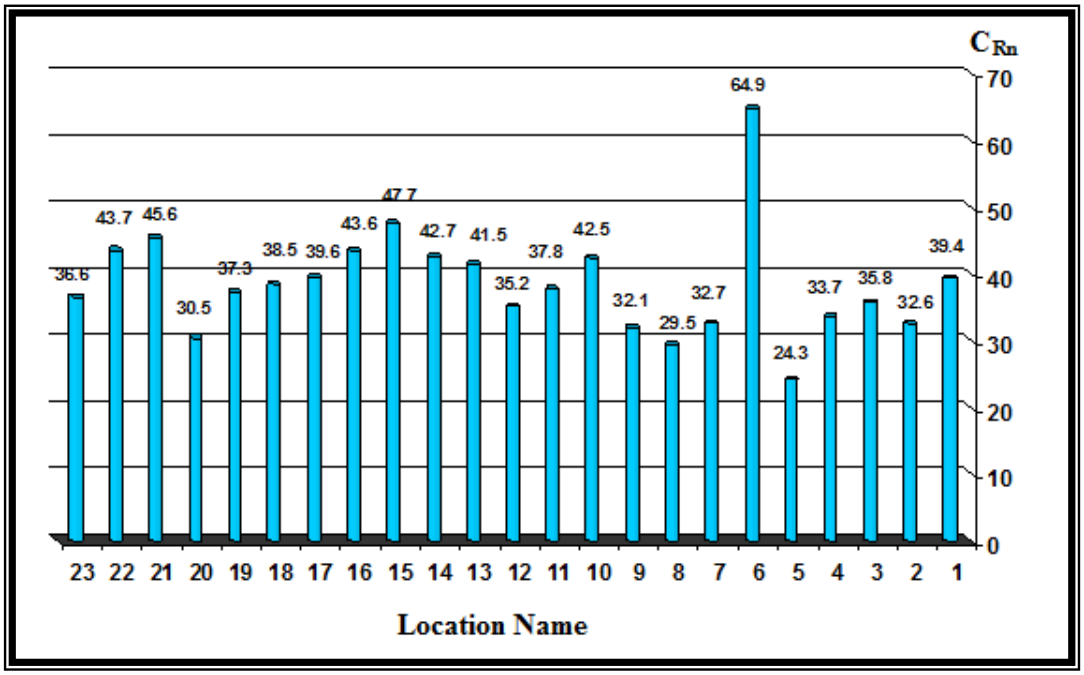

Figure 3. C_{Rn} in indoor rooms and Laboratory in science college buildings in the university of Mustansiriyah.

5. Conclusions

Indoor C_{Rn} level in rooms and Laboratory was determined in a total of twenty-three rooms or Laboratory. Indoor C_{Rn} in all rooms and Laboratory of Department Physics in science college building is lower extent (200-300Bq/m^3) and the parameters (CPPP), (AED), (PAEC), (E_P) values were lower than the permissibility limit value, the study offer that internal air in rooms and Laboratory of Department Physics in science college buildings in the university of Mustansiriyah is not dangerous to students and teachers alike.

Abstract. This research succeeded in the prepared of iron oxide NPs using rose plant extract with rust iron extract at 300 ^{o}C for two hours by simple chemical method. Iron oxide NPs have been developed as an death of antimicrobial as an alternative to toxic chemical drugs to prevent negative effects on human health. Iron oxide NPs were diagnosed using X-ray diffraction (XRD) analysis, Field Emission Scanning Electron Microscopy (FE-SEM) analysis, and Photoluminescence (PL) spectrum. XRD measurements explained the small crystalline size (61 nm) with (inverse cubic) structure (wustite) for ($Fe_{0.911}O_4$) NPs at 300 ^{o}C using rose plant extract. FESEM showed the average grain size of $Fe_{902}O$ NPs (wustite) rose plant extract at 300 ^{o}C was 79.59 nm. PL spectrum determined a blue shift for the optical near band edge value was 2.75 eV for $Fe_{0.911}O$ NPs (wustite) at 300 ^{o}C. Iron oxide NPs were applied in antimicrobial for removal of toxic bacterial by diffusion method. The success of this work will open wide new horizons for us in solving the problem of spent iron and how to get rid of it and the manufacture of new nanoparticles in medical treatments.

Keywords: Iron oxide NPs; Rose plant extract; Rust iron extract; Antimicrobial activity.

1. Introduction

Nanoparticles (NPs) could be defined as small particles with diameter ranging less than 100 nm in dimensions, synthetic of inorganic or organic materials, having new properties as contrasted to the bulk materials [1]. Among the NPs, Iron oxide NPs are significant materials which have great future advantages compared to other materials [2] special physiochemical properties, such as low toxicity, high catalytic activity, small sizes, with different physical properties [3-5]. At the present time human activity in all areas of life is associated with chemicals and these substances have great harm to the human body, especially a number of these substances are constantly increasing in used, and it is agreed that there is no completely safe chemical substance and in return it is not. There is a chemical substance that can be considered completely harmful. Chemists in the middle ages suffered from debilitating and other diseases due to the damages of explosive and toxic materials that they worked to, and serious environment troubles began for show in a world at the beginning of the 17 century due to cinder released of the mines, in addition into fabrication of pigment and other chemicals of charcoal tar in Germany through the 18 century, which led to emergence of toxic and polluting secondary compounds for the

environment, and the steadily increasing quantities and numbers of chemical compounds manufactured in 19 century, counting steely and waste iron rust, lead batteries and petroleum, and with it amount of pollutants and harmful materials raised in environment, among these materials a focus come to iron metal which play a major element in the universal due to the varied uses in too many applications and industry. The overmuch uses of iron metal, this led to founding as thousands of tons from scrap and rubbish rusty iron in the garbage yard without any possible resolution to reuse or benefit from it till now which make the perilous environmental issue in different places in this world.In summery the iron consumed and the huge quantities of it formed a burden on the environment and became a real problem for disposal at the present time.Bio-synthesis of iron oxide NPs using plant extracts as biological components has numerous interest such as cost-effectiveness, atom economy, simplicity, benign, nontoxic, elimination of toxic and dangerous materials, easy availability and removal toxic substances for environmental remediation [6-8]. Wüstite (FeO) is a mineral form of iron (II) oxide found with meteorites and native iron. It has a gray colour with a greenish tint in reflected light. Wüstite crystallizes in the isometric-hexoctahedral crystal system in opaque to translucent metallic grains. The Literature Review of this work: In (2020) R. C. Popescu et al., The synthesized of iron oxide NPs and application in cancer treatments [9]. In (2018), Helale Kaboli Farshchi, et al., Synthesized iron oxide NPs using Rosemary extract and application in cancer treatments [10].In (2017), Sathiskumar G., et al., Synthesized iron oxide NPs using Couroupita guianensis Aubl by (chemical method). Application in vitro anticancer activity and antibacterial activity [11]. In (2018),Shraddha C.,etal.,Synthesized of iron oxide NPs using henna leaves extract by(chemical method). Application of iron oxide in antimicrobial [12]. In (2019),SaeedJ.,etal.,Prepared iron oxide NPs using plant extract. Application in antimicrobial [13].The novelty of this work that all the materials used (which it is used in the first time as the authors knowledge) considered as a waste matter without any cost mentioned to produce valuable and useful NPs materials. In addition, there are no chemical compound used in this research, neither the raw materials nor the final product. All materials used are natural without any supplement. In this work, iron oxide NPs were prepared by mixing wasted iron rust with (rose plant) extract at the (300) oC for two hours. The antimicrobial treatment using iron oxide NPs by diffusion method. The iron oxide NPs (Fe0.911O) were characterization by X-ray diffraction (XRD) using "(XRD6000 Shimadzu, Company/ Japan), Filed EmissionScanning Electron Microscopy (FE-SEM) using (Tescan Mira3 FESEM-Czechia)". Also, the photo luminance (PL) by (Jobin Yvon HR800UV).

2. The experimental part

2.1. Apparatus and equipment

The plants have been collected from the local market in (Baghdad /Iraq), as a preliminary work. The wasted iron specie were pruched from locally (Baghdad / Iraq). All glass ware were cleaned by distilled water (distilled water device, Company / Gallenkamp, England). In addition, all solutions in this work were prepared via distilled water.The beneficial components present in the rose plant are flavonoids, anthocyanins, terpenes and glycosides, and it has been found that the components have the most therapeutic properties in leaf plants are the phenolic compounds that are antioxidant, depression and inflammatory, and the rose leaves contain a number of vitamins such as vitamin E, D, C., A, and vitamin B3 [14].

2.2. The prepared of the (rose plant) extract.

The rose plant were washed with distilled water and then dried under sunlight for 5 days. Then the rose plant were ground using an electric grinder. The mixing 7 gram from rose plant powder with 80 ml from distilled water on magnetic stirrer at 70 ^{o}C for 1.5 hours. It observes the colour change of the solution and this is an indication of the formation of an iron oxide NPs material. The final solve are

freeze to room temperatures and filter using whatman filter sheet. Figure 1 explains the phases of transferring the *(rose plant)* into the extract.

Figure1. shows the phases of preparation the plant extract (*rose plant*), A) *rose plant*, B) *rose plant* powder, and C) *rose plant* extract.

2.3. The prepared of wasted iron (rust) extract

The weight of the wasted iron (rust) used to synthesis iron oxide NPs is 146.0 g. The wasted iron piece was washed with distilled water to get rid of the impurities attached to it. After that, the wasted iron piece was placed with 500 ml of distilled water in a glass flask under the sunlight for 8 days. Then the wasted iron extract was obtained in red color with a size of 250 ml and stored in sealed tubes to synthesis iron oxide nanoparticles. Figure 2 explains the phases to synthesis wasted iron (rust) extract from wasted iron specie (rust) with distilled water.

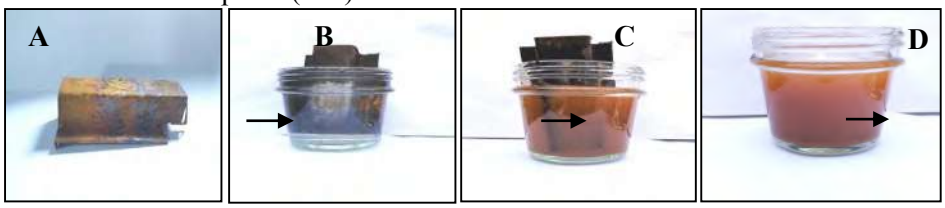

Figure 2. shows the steps for preparation a spent iron extract, A) iron specie, B) iron specie with distilled water before exposes for sunlight, C) spent iron extract after exposes for sunlight, and D) spent iron extract.

2.4. The prepared of iron oxide NPs ($Fe_{0.911}O$) of (rose plant) extract and wasted iron extract (rust).

The Prepared of iron oxide NPs from mixing 250 ml of wasted iron extract (rust) to 100 ml from rose plant extractor. After that, solve were place on hotplate stirrer at 70 °C for 60 minutes. It observes the solution during synthesis, the colour from extractor reaction changed suddenly from translucent offlight pink into black, referring the formed of iron oxide NPs. The resulting solve was cooled at room temperature. For obtain the nano-powder of iron oxide solve, the taken 30 ml of iron oxide NPs solution was putted in a ceramic vine with steamed at 200 °C for 2 hours. Lastly, iron oxide NP solves were stocked in sealed serum tubes to further diagnostic. In figure 3 (A-D) explains the phases to synthesis for iron oxide NPs from rose plant extractor and wasted iron extract (rust).

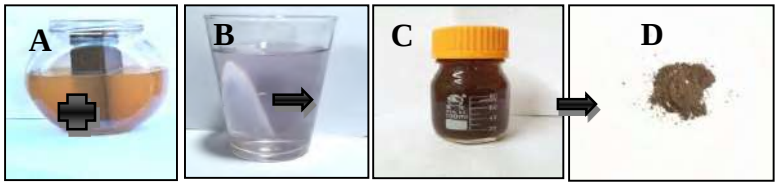

Figure 3. The transfering phases of the wasted iron specie into extract under sunlight for 5 dayes, A) wasted iron specie, B) *rose plant* extract, C) iron oxide NPs, and D) iron oxide NPs powder.

2.5. Characterization of iron oxide NPs ($Fe_{0.911}O$) created using (rose plant) extract.

The specimen was determined by XRD analysis of via the results supplied using the joint committee on powder diffraction standards (JCPDS) card. The scale range of XRD measurements were collected between 20°–70° by use a step-by-step examination model (XRD-6000, Shimadzu) employment at 30 mA and 40 kv. The PL spectrum were resolved by a double beam spectrophotometer (Jobin Yvon HR800UV).

2.6. Antibacterial activity from the spent iron extract with (rose plant) extract.

The microbial cultures were providing by the Microbiology laboratory of the University of Baghdad-College of Education for pure science/ Ibn al-Haitham. This test carried out by agar well diffusion methods in sterile petri-dishes with 90 mm diameter containing sterile nutrient agar medium. Nutrient agar medium was prepared by dissolving 0.5 g peptone this provides organic nitrogen; 0.3 g yeast extract these contributes vitamins, carbohydrates, nitrogen, and salts; 28 g agar this gives the mixture solidity in 1000 ml distilled water. pH was adjusted to 6.8 at 27 ^{o}C. These ingredients are combined and boiled for approximately 15 minutes to ensure they are mixed typically at 121 ^{o}C and poured into petri dishes which are covered immediately until it becomes solidified. After that, iron oxide NPs were dissolved in Dimethyl Sulphoxide (DMSO) solvent with concentration 30 mg/ml. The freshly prepared bacteria were swabbed over the surface of the petri-dishes. Wells of 8 mm diameter each were made, in the medium of bacterial and fungal for each plate using sterilized gel puncher/crok borer. Each well contains 40 µL of iron oxide NPs, and control (DMSO) for bacteria and fungi respectively at desired concentration is introduced into the well. The test samples were incubated at $\pm$25 ^{o}C for 24 hours for bacteria and fungi followed by the gauge of diameter of inhibition zone in (mm). Percentage of inhibition zone have been measured using the following equation:

$$Inhibition\ Zone\ (\%) = \frac{Diameter\ of\ the\ inhibition\ zone\ in\ mm}{Diameter\ of\ pertiplate\ (90\ mm)} \times 100\% \quad (1)$$

3. Results and discussions

3.1. Synthesizing and Characterizing of iron oxide NPs from (rose plant) extract.

Iron oxide NPs prepared bythe modern plant rose plant extract; the extract is mixed with spent iron extract at different reaction conditions. The factors identifying a terms of the rose plant extract to control the rate from iron oxide NPs formation as well as their filed and stability. The phytochemicals inside *rose plant* extract have ability to less spent iron ions in short time. In addition, *rose plant* extract plays an important role from reduce and stabilize factors in iron oxide NPs prepared way for simplify iron oxide NPs. The beneficial components present in the rose plant are flavonoids, anthocyanins, terpenes and glycosides, and it has been found that the components have the most therapeutic properties in leaf plants are the phenolic compounds that are antioxidant, depression and inflammatory, and the rose leaves contain a number of vitamins such as vitamin E, D, C., A, and vitamin B3, which are responsible to synthesis of iron oxide NPs.

3.2. The XRD analysis of iron oxide NPs ($Fe_{0.911}O$)prepared from (rose plant) extract with rust iron extract.

Iron oxide NPs were bio-synthesis by a chemical way from mixing the (*rose plant*) extract with rust iron extract at 300 ^{o}C in Figure 4. The peaks high of the crystalline ($Fe_{0.911}O$) phase (Wustite,space group Fm-3m, JCPDS no.01-079-1880) is (*220*) corresponding to (*111*), and (*200*) millers indices with the face centre cubic (F.C.C), as shown in Figure 4 [15-16]. The results the phases, and crystallite size of

iron oxide NPs ($Fe_{0.911}O$) shown in Table 1. The crystallite size (D) was determined Applied the following Scherrer's formula [17-18].

$$D\ (nm) = \frac{k.\lambda}{\beta cos\theta} (2)$$

Where k called shape factor (0.9), λ the wavelength (0.15418) nm (CuK_{α}), β is full width at half maximum (FWHM) and θ is diffraction angle [19].

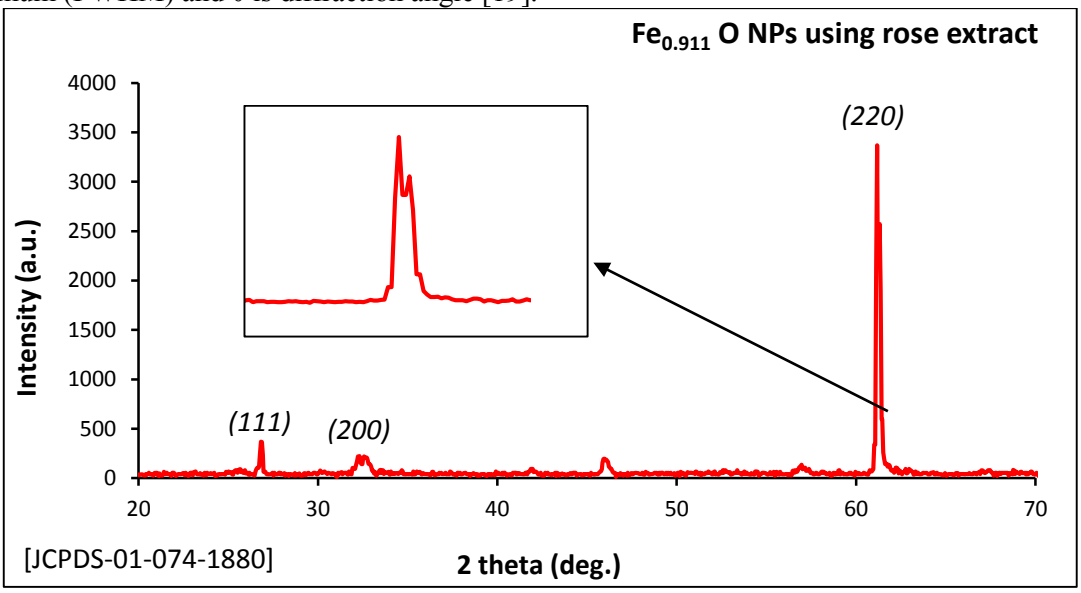

Figure 4. XRD analysis shows of the iron oxide NPs prepared from rust iron extract with the(rose plant) extract, the crystalline $Fe_{0.911}O$ phase (wustite,space group Fm-3m, JCPDS no.01-079-1880) at 300 °C.

Table 1. XRD analysis shows of the crystallite size for iron oxide NPs prepared from rust iron extract with (*rose plant*) extract.

Plant extract	Materials	Temperature (°C)	(*hkl*)	FWHM	Crystallite size D (nm)
Rose Plant	$Fe_{0.911}O$ (wustite)	300	(220)	0.13	61

3.3. The FE-SEM images of iron oxide NPs (Fe0.911O)prepared from (rose plant) extract with rust iron extract.

.

The FE-SEM images shows the size distribution and the surface morphology of eco-friendly iron oxide NPs created from the (*rose plant*) extract with rust iron extract at 300 °C. The grain average size is from (71.59) nm with the morphology is (nano-Slices) structure of the $Fe_{0.911}O$ NPs (Wustite) at 300 °C, as shown in Figure 5 (A-B).

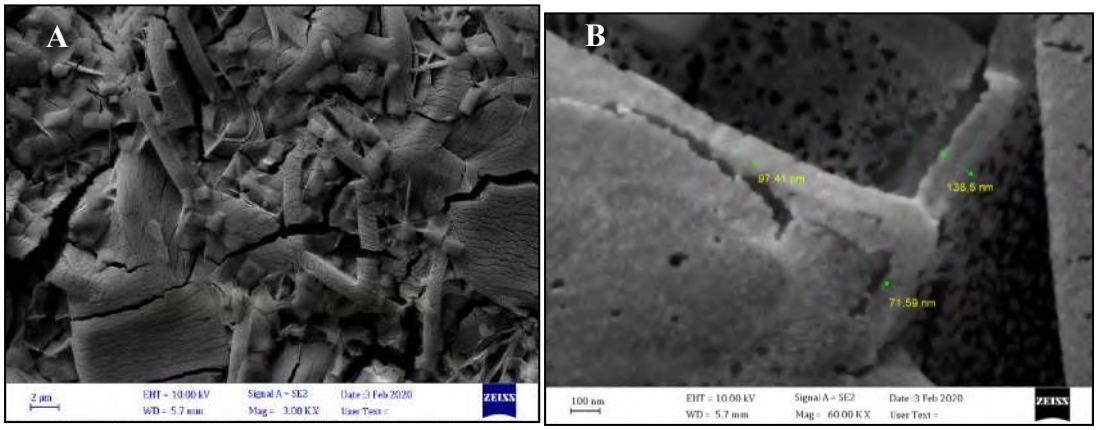

Figure 5. A-B FE-SEM images shows the results of iron oxide NPs prepared from rust iron extract with *rose plant* extract, at 300 ºC.

3.4. The PL spectrum of iron oxide NPs ($Fe_{0.911}O$)prepared from (rose plant) extract with rust iron extract.

The PLspectrum shows the near band edge of eco-friendly iron oxide NPs created from the (*rose plant*) extract with rust iron extract at (300)ºC by a chemical way. The near band edge is (2.65) nm with the exaction band is 325 nm of $Fe_{0.911}$ONPs (Wustite, the near wavelength (469) nm at 300 ºC, as shown in Figure 6.

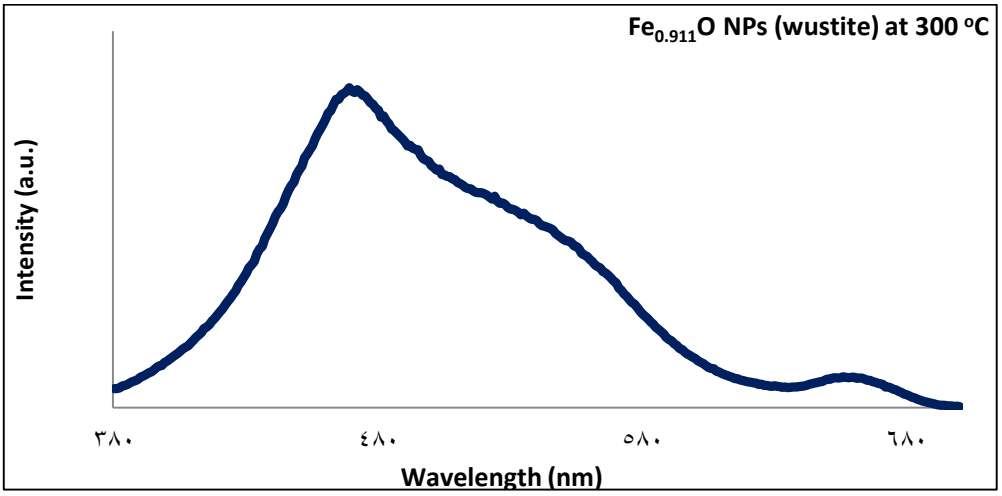

Figure 6. The PL spectrum shows the results of iron oxide NPs prepared from rust iron extract with rose plant extractat 300 ºC.

3.5. Antibacterial and antifungal activity of iron oxide ($Fe_{0.911}O$)NPs using rose plant extract.

The efficacy of anti-bacterial and antifungal activity in terms inhibition of zones (mm) has been measured against four slander bacterial isolates: gram-positive bacteria (B. subtilis and S. aureus), gram negative (K. pneumonia) and (candida). The bio-synthesis of iron oxide NPs showed the good effectiveness of inhibition percentage, but bios-synthesis of iron oxide NPs prepared from *rose plant* extract were more effective than rose plant only extract. The antibacterial activity of iron oxide NPs is chiefly due to the release of iron ions all have attached to the bacterial cell wall due to electrostatic attraction. Furthermore, the metal ions are not only interacting with the surface of membrane but can

also penetrate inside the bacteria. NPs may react with the thiol group (-SH) in the cell wall of the bacteria and not allow the transport of nutrients through the cell wall. The protein decreases inside the cell, eventually causing the cellular death. Or the other reason is that the smaller particle size of the synthesized matels NPs connected with (linked with) the large band gap and consequently, more available oxygen will lead to the generation of a higher concentration of reactive oxygen species (ROS) to enhance antimicrobial activities. However, the activity depended on large surface area to volume, concentration of iron oxide NPs, crystalline structure, and particle shape. The results of iron oxide NPs ($Fe_{0.911}O$) prepared using (*rose plant*) extract using, dose give good result against (k. pneumonia).

It notes the highest rate of destruction of negative and positive bacteria of both types when using iron oxide ($Fe_{0.911}O$) NPs, as shown in Figure 7 and in the Table 2.The disk-diffusion agar method tests the effectiveness of antibiotics on a specific microorganism. An agar plate is first spread with bacteria, then paper disks of antibiotics are placed atop of it. The bacteria are then allowed to grow on the agar media and then observed for growth and effect of the antibiotic on it.

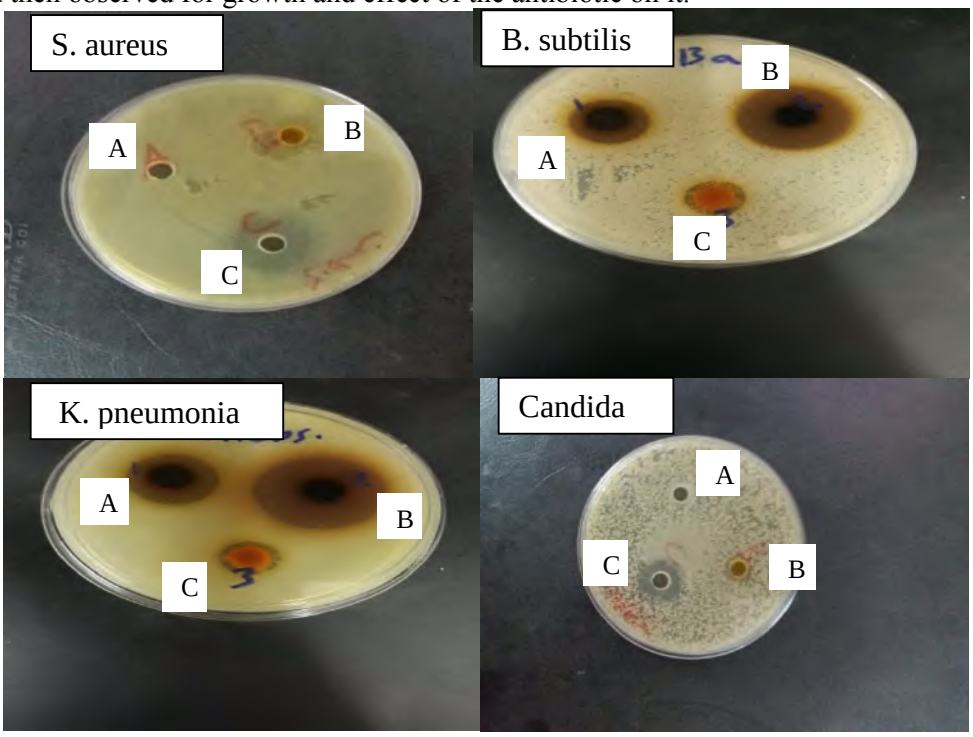

Figure 7. Antibacterial and antifungal activity (gram-nagative and gram-postive) of A. rose plant extract only, B. Fe0.911Ousing rose plant extract, C. rust iron extract.

Table 2. results inhibition of zone of material iron oxide NPs, againts bacteria and fungi at 30 (mg/ml) concentrations.

Com	Staphylococcus aureus	Bacillus subtilis	Klebsiella pneumoniae	Candida albcains
A	-	30	32	-
B	20	38	45	23
C	25	10	8	-

4. Conclusion

This work succeeded in preparing iron oxide nanoparticles using natural extracts, and this success will open new and broad horizons for us in solving the problem of spent iron and how to get rid of it and the manufacture of new nanoparticles in medical treatments. Antibacterial of iron oxide NPs were certain by investigating the inhibition of zones which were from 45 mm to gram-negative bacteria (klebsiella pneumoniae) and 38 mm to gram-positive bacteria (Staphylococcus aureus and Bacillus), but were results are 23 mm to candida activity. Also, this work succeeded in studying the effective effect of bandaging of bacteria, and therefore excellent results were obtained in killing and destroying bacteria. Thus, the ability of these NPs to preserve human life from diseases caused by these bacteria was proven.

Abstract. Superconducting compound $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$ were Synthesized by method of solid state reaction, at 1033 K for 160 hours temperature of the sintering at normal atmospheric pressure where substitutions Yttrium oxide with Strontium. When Y_2O_3 concentration (0.0, 0.1, 0.2, 0.3, 0.4 and 0.5). All specimens of $Bi_2Sr_2Ca_2Cu_3O_{10+\delta}$ superconducting compounds were examined. The resistivity of electrical was checked by the four point probe technique, It was found that the optimum and maximum transition temperature T_c = 125 ^oK. The crystal structure studied by using XRD analysis and it was showed that the all specimens have tetragonal structures. Bi-2223phase increase by increasing Y_2O_3 concentration up x=0.4, The increasing addition Yttrium oxide concentration produce increasing in high-phase (Bi-2223) and c lattice parameter.

Keywords: Transition temperature: Superconductors; $Bi_2Sr_2Ca_2Cu_3O_{10+\delta}$oxide; XRD

1. Introduction

Superconducting is a phenomenon of total loss of electrical resistivity in some materials when cooled to a low temperature, and these materials are characterized by their ideal conductivity and diamagnetic behavior [1]. The primary properties of interest in solid-state physics at extremely low temperatures for many compounds and elements are electrical resistivity. Where there are two types of superconducting materials [2]. Depending on the way in which the electrical resistance decreases when the temperature decreases until it becomes zero. The first type of materials the resistance decreases suddenly when cooled to the critical temperature degree, and the other type is gradually decreasing until it becomes zero, meaning that it has two critical temperatures. The first type includes metals and metal alloys, including elements such as tin, tin Aluminum, forms of different metal alloys, while the other type includes ceramic materials with a perovskite composition, such as some high-doping semiconductors and some ceramic compounds. Where the second type contains layers of copper oxide and these compounds are referred to as “cuprates Superconducting materials" with high critical transport temperatures, and the phenomenon of superconductivity is not obtained in noble metals or in magmatic metals [3-5].

The bulk of superconducting materials are additives and alloys, which are not pure elements. The temperature of the transfer of compounds affected by substitution elements is completely different from pure compounds or metal alloys and their parts. In fact, many researchers have observed that there is a very clear rise in the temperature of transformation in alloys and compounds upon partial replacement of some elements of the compound with other elements other than it in the pure compound [5]**.** One of the very important properties of a material is electrical resistance, and it is the most common method for determining the transition temperature of a superconducting material. In this article, some measurements will be made of the structural and electrical properties of samples of $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$with various x, such as X-ray, electrical resistance and the effect of partial precipitation of Sr with Y element.

2. Experimental Work

The $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$compounds with (x=0.1, 0.2, 0.3, 0.4, 0.5) were synthesized by the (SSR) method after weighing specific quantities of high-purity pure powder oxides with a purity (99.99%) of the Bi_2O_3,Sr_2O_3,Y_2O_3 ,CaO and CuO. The materials included in the composition of the compound were weighed using a high sensitivity balance of up to (10^{-4}) g arranged, and the oxides of the reactants were mixed with each other using a slurry with the addition of a little isopropanol (C2H3O5) to make the mixture homogeneous. To get rid of the water vapor in the mixture, the powders were dried for 1.5 hours at a temperature of 150 ° C, after which the mixture was grinded by a spiral electric mixer for a period of six hours in order to obtain fine homogeneous powders.The powders were pressed with a hydraulic press of 0.7G Pa for a period of 2 minutes, in the form of tablets with a diameter of 0.75 cm and a thickness of 0.3-0.35 cm.

Samples were placed in a thermal furnace for the purpose of sintering and its temperature was raised to 760 ° C for a period of (160 hours) with an average rise (5 ° C per minute) to obtain smooth bonding and to ensure the optimum gradual diffusion between the atoms to form the compound. Then the samples were cooled to room temperature at 5 ° C per minute (same heating rate).

The samples were examined with X-ray diffraction, the (X-ray) diffraction angle ranging from (10-80) to obtain the samples structural properties. The crystal lattice constants (a, b, c) were mathematically calculated using the values of each d and (Miller indices) for the observed patterns during a computer program [6-8].Volume fraction phase in addition, density of mass was measured, and Volume fraction phase calculation based on the following formula [7-8]:

$$\boldsymbol{Vph} = \frac{\sum \boldsymbol{I^{o}}}{\sum \boldsymbol{I^{o}} + \sum \boldsymbol{I1} + \sum \boldsymbol{I2}} * \mathbf{100\%} \qquad \ldots\ldots\ldots\ldots \quad (\mathbf{1})$$

The concentrations of hole-carrier per Cu ion, It is calculated by means of the formula of following [11]:

$$\boldsymbol{P} = (\mathbf{0.16}) - \left[\left(\mathbf{1} - \frac{\boldsymbol{T_c}}{\boldsymbol{T_{c(max)}}}\right)/(\mathbf{82.6})\right]^{\frac{\mathbf{1}}{\mathbf{2}}} \ldots\ldots\ldots\ldots\ldots (\mathbf{2})$$

P is the concentrations hole-carrier per Cu ion,

Four probe method at temperature range (77-300) K was used to measure the resistivity(ρ). Critical temperature (Tc) calculated using the relation [9].

$$\boldsymbol{\rho = (R*A)/L} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots \mathbf{(3)}$$

Where R is resistance of electric, A is specimens area and L is specimens length.

3. Result and Discussions

3.1 structural properties

XRD was examined for pure samples $Bi_2Sr_2Ca_2Cu_3O_{10+\delta}$ and samples containing Y_2O_3 $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$ for a deflection angle ranging between (10^{o} to 80^{o}), the results shown in Fig. 1

Indicated that all samples have polycrystalline structure with a tetragonal structure. The illustration the (XRD) pattern for $Bi_2Sr_2Ca_2Cu_3O_{10+\delta}$doped by ($Y_2O_3$) shows that all the samples contain a high percentage of the high temperature phase $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$(Bi-2223) and a few low-intensity phase peaks (Bi-2212&Bi-2201) that have a low temperature, with some impurity phases appearing[10]. By comparing the phase ratio (Bi-2223) in the pure sample and the partially replaced samples with yttrium, it was found that there is a significant increase in this phase corresponding to a fluctuation in the phases (Bi-2212) and (Bi-2201) as well as in the percentage of impurities that accumulate it may be due to defects in The internal structure of the compound. the substitution of $Y_2O_3$by SrO produce very small shifting in the diffraction angle 2Θ and change in magnitude of peaks intensities. Calculation of lattice parameters was shown in Table 1. This table noticed that the increase of yttrium substitution concentration produce increasing in c-axis values due to the variation in radius of the ionic.

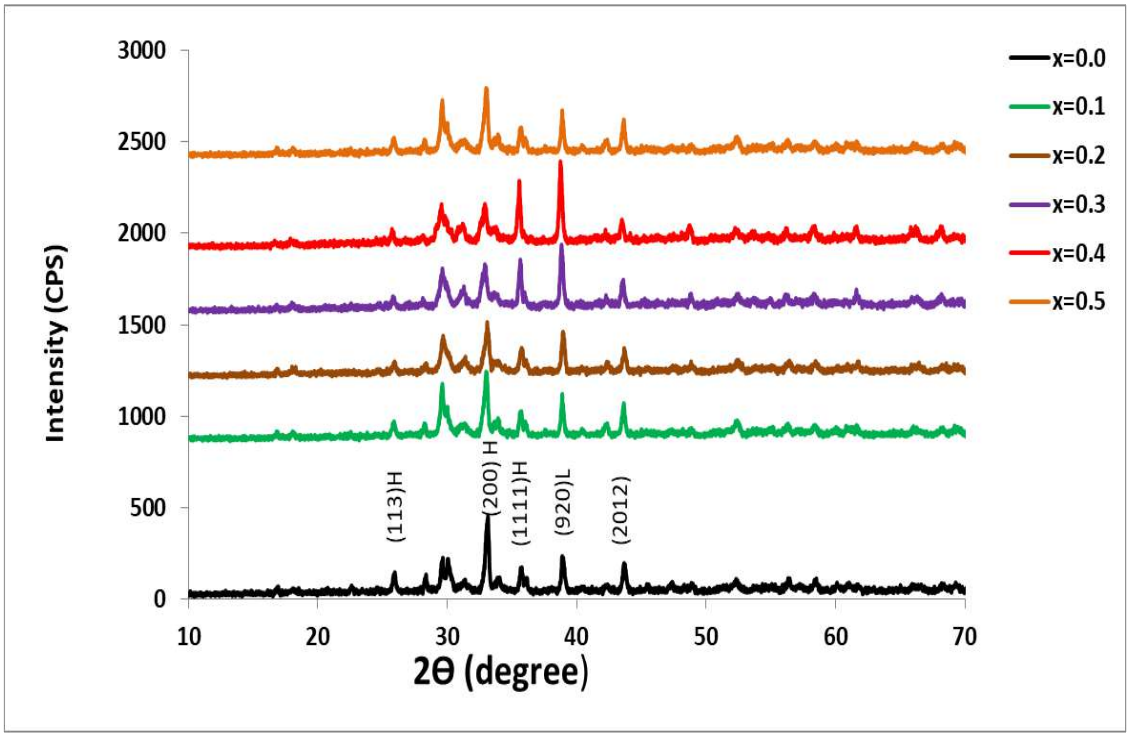

Fig.1. XRD pattern of $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$ compound (x=0.1, 0.2, 0.3, 0.4 and 0.5).

The change in the (c) axis can be attributed to the increase in the oxygen percentage resulting from substituting (Y_2O_3) instead of (SrO) and that this increase in oxygenation is taken by the double bismuth oxide layers which cause stronger bonding due to the equivalence of yttrium tertiary. It leads to an increase in the strength of the ionic bonds formed in the bismuth oxide layers and thus changes the lattice constant (c).The parameters of lattice a, b, c based on method of Cohen's least square, calculation by software program, density of mass D_m and fraction of volume (V_{phase}) were calculated from the above equation which are revealed in Table 1. It was clear show that Y_2O_3 concentrations increasing produce variations on a, b, c values, concentrations of hole-carrier, c/a, mass density and volume fraction of unit cell [6-8].

Table 1. Values of a, b, constants, ρ_M,c/a, V_{phase},Vof $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$ compound (x=0.1,0.2,0.3,0.4 and 0.5).

3.2 Electrical properties

The electrical properties of the samples were examined by relying on the four-sensor technique, where the voltage and current readings were taken as a function of temperature, and then the electrical resistance was calculated as a function of temperature and was drawn in Fig. 2 , shows a measured of temperature versus resistance (T) at variable concentrations of Y. From Fig. 2, it is noticed that resistance of electrical as a function of the temperature of the $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$ compound with (x=0.1,0.2,0.3,0.4 and 0.5) that all sample ratios showed metallic behavior at temperatures higher than the initial transition temperature ($T_{c(onset)}$) and then fell to zero at the transition temperature. Depending on the ratios of yttrium and that the concentration x = 0. 4. The best partial substitution ratio for yttrium oxide is (125K). This can be attributed to the fact that the crystal structure became perfect with the presence of Y_2O_3 and that the transition width (T_c) is the narrowest compared to the other samples due to the width range. It shows the transition and represents the purity of the superconducting material.The transition temperature values (Tc) for $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$ when x = 0, 0.1, 0.3, 0.4 phases of 115 K, 119 K, 118 K and 122 K, respectively. We can observe the increase in the degree of critical temperature values (Tc) up to It reaches the best sample by partially substituting yttrium oxide at a concentration of x = 0.4 so that a critical transition temperature of 125K is obtained[11].

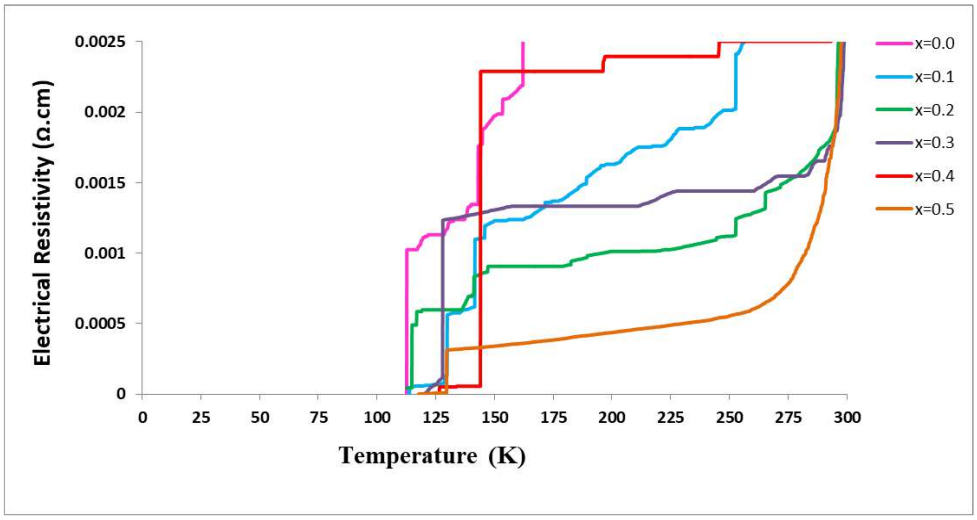

Fig.2. The Electrical Resistivity as temperature function of $Bi_2Sr_{2-x}Y_xCa_2Cu_3O_{10+\delta}$ compound (x=0.1, 0.2, 0.3, 0.4 and 0.5).

4. Conclusions

Through our experimental research in the study of the effect of partial substitution of yttrium oxide with Strontium of the superconducting compound ($Bi_2Sr_{2-x}Ca_2Cu_3O_{10+\delta}$), where we were able to obtain superconducting samples under the preparatory conditions that we adopted during the work. Through the X-ray diffraction analysis, it was revealed that all samples have a quadruple crystal structure and that the partial substitution (Y_2O_3) did not change the crystal structure of all samples with respect to the pure sample. Also, all samples contain phases (Bi-2223, Bi-2212,Bi-2201) with low levels of impurities. As for the electrical resistance tests, all samples revealed It has a metallic behavior where its resistivity changes with a decrease in temperature before transforming into the superconducting state and the best sample was obtained at a concentration of x = 0.4 and equals 125K.

Abstract. The PV solar system on the rooftop of buildings is a good source of renewable electric energy. Iraq has very large number of educational institutions with large non-invested rooftop with shortage of electrical energy supply. The present work aims at construction a simulation for PV- System action installed on rooftop of educational institutions in Baghdad using Green Power Solution (GPS) and PV-Syst programs. Based on the surface area of the schools' roofs, the GPS program estimated three main PV-Systems which can be carried out, 63kW, 50kW, and 30kW in order to supply the electric power to selected school. Due to allocating few hours for school's studying time along the year, the suitable PV-System is on-grid connection. The results indicated that the annual system performance ratio is 81.9% and the annual output power of these systems were 111.0 MWh/year, 88 MWh/year and 51.4 MWh/year respectively, 19.3MWh/year of them was consumed for this school and the rest is a feedback for grid. This green generation reduced the amount of emission CO_2 by 73.981 tons, 62.216 tons and 36.3398 tons per year for systems 63kW, 50kW and 30kW respectively. The results also appear that the initial capital cost of each system can be recovered during the first six years of system operation.

Keywords: PV-Solar system, performance of PV- module, PV-Feasibility study, rooftop solar system, Carbon dioxide emissions.

1. Introduction

Electric generation by PV Solar system is one of the suitable means in a generation the power in Iraq, due to the negative environmental influence of fossil fuel, shortage in supply of electric energy, losses on the transformation sector, and the shortage between the generation of energy and increasing of demand [1]. Iraq has a high rate of solar irradiation and the maximum value of irradiation distributed in the south and mid of it, the average annual irradiation of Baghdad is about 5.27 kWh/m2/day [2]. The Iraqi Ministry of Electricity has adopted a new policy by generating solar power at the center of loads in city where the domestic sector and government buildings are the largest in energy consumption. The most important projects are the 1MW project at the Ministry of Electricity and the 100 kW project in the oil training center department and other smaller projects [3]. Hashim et al achieved an assessment and evaluate the performance of 15 kW system for 12 months period of the year 2018 under Baghdad environment and compare it with simulated software of PV system, the anual energy yield was 23.77 MWh/ year, it is found that the total of annual energy yield forecasted by PV-Syst software was 24.08 MWh/ year, annual average performance ratio was75.55% with system efficiency of 13.27% [4]. Mensah et al presented a study of a Grid-Tied of PV solar system in the northern part of Ghana at

Navrongo. They found that performance ratio was 70.4% and the mean annually generated energy was 3547.8 MWh and payback period time is found to be 14.95 years [5]. Environmentally, there are many factors influence negatively on solar PV performance such as increasing in environment temperature [6], and dust [7, 8]. On the other hand PV solar systems can reduce the emission of CO_2 [9, 10]. Dondariya et al, modeling and study the feasibility of the system in the proposed location. These can be done on the various available software platforms and the reports generated can be used to compare and get the best-suited model among them in implementing the same at field level [11]. Many projectors had achieved for a green generator in the world. Tesla with support from the South Australian Government is developing a network of up to 50,000 home solar PV and Power wall battery systems across South Australia – all working together to form the world's largest virtual power system. A virtual power system is a network of home solar photovoltaic (PV) and battery systems working together to generate and store energy, and feed energy into the grid. [12]. Lazaroiu et al, 2016, studied and analyzes the optimized operation of a virtual power system owner on the day-ahead market for maximizing his overall profit. The virtual power system is composed of distributed energy resources with variable produced power, energy storage systems, and classical generating units [13]. Al-Khazzar study the performance of a 5 KW Photovoltaic grid tied system is suggested to cover the demand of an Iraqi primary school. The PV-Syst simulation software is selected, the performance ratio for the system in Baghdad is 0.825 and about 9.82MWh is generated by the system per year, 62.7% is consumed by the load and the remaining is injected to the national grid. The results showed that the primary capital cost is $5,442 which is repaid after five and a half years [14]. Alfahed et al, study the 4.0kW stand-alone Solar PV system for providing electricity to a sample home in the Haur Al-Hammar region in the south of Iraq, by using mathematical equations with Excel worksheet and PVsyst 6.68 software simulation package [15]. The present work aims at build a simulation for green generation by PV-Solar system installed on rooftop of schools using Green Power Solution (GPS) amd PV-Syst programs.

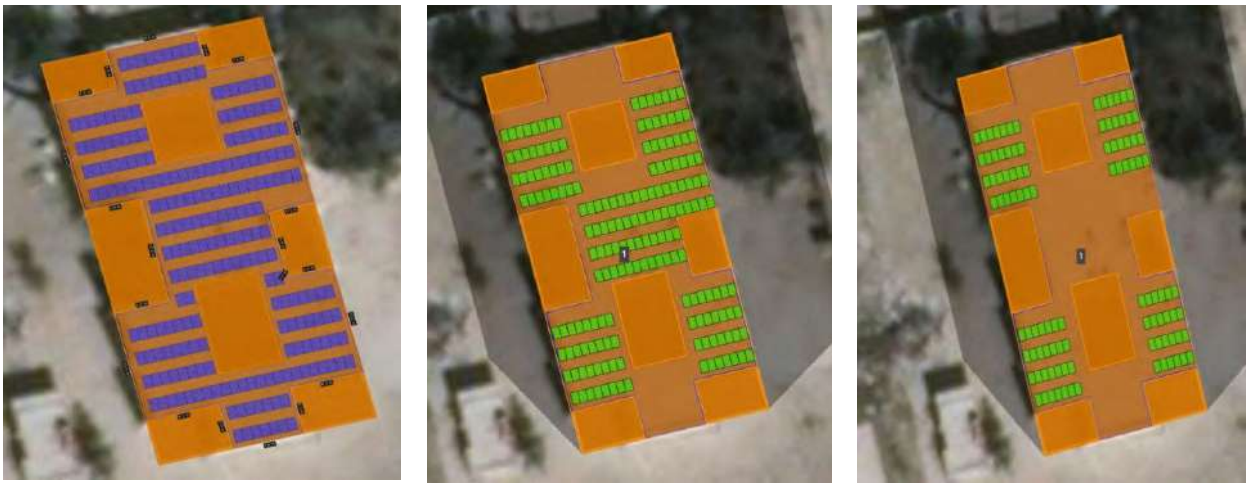
2. System Description

The number of public school buildings in Iraq in 2013 are (17435), including (2520) in Baghdad [16].The schools in Iraq (kindergartens, primary, intermediate, preparatory) ranging from a small area to a large area. The school chosen for the present study with unused rooftop is a secondary school (Al-Maqdam) (33.3489923, 44.4739866) in the Al-Baladiyat district in Baghdad. The study achieved by a PV-Syst. There are several hundred of schools having same design and area, Figure 1 shows the satellite image for the school location.

Figure.1. Satellite image for the school located in Baghdad- Iraq

The first system designs to generate 63kWh and the number of modules are 225. The solar panels are considered to be south-ward, the ideal direction for fixed systems, as shown in Figure 2a. The tilt angle for modules is 15o to suitable for the summer season where the energy demand is Maximum in Iraq. The second designs with number of modules are 178. The system designs to generate 50kW.

The solar panels are considered to be southward as shown in Figure 2b with tilt angle for modules is 15o. From the figure we observe the full exploitation of the surface area of the school. The third design with the number of modules is 104, the system designs to generate 30kW. The solar modules are considered to be southward as shown in Figure 2 c with tilt angle for modules is 15o.



.a b c

Figure 2. Schema of systems a-63kW, b-50kW, c-30kW.

The solar modulestype that can be used isREC 280TP (280W) which is efficient and bear high temperatures. The specification of the PV module is listed in Table 1.

Table 1. Technical specification of PV module 280W [17]

Parameter	Value	Parameter	Value
Dimensions	1958*9991*50(mm)	p_{max}	280(W)
weight	27 (kg)	Temperature coefficient V_{OC}	-0.31(V/^{o}C)
No.of Cells	72 (in series)	Temperature coefficient I_{Sc}	0.045% /^{o}C
I_{Sc}	9.40(A)	Temperature coefficient P_{max}	-0.39 %/^{o}C
V_{OC}	39.2(V)	Module efficiency	17%
I_{mp}	8.78(A)	NOCT	44.6(^{o}C)
V_{mp}	31.9(V)	Type of cell	Pc-Si

Component of 63KW, 50KW and 30KW system is listed in Table 2.

Table 2. Component of 63KWh system.

Component	Name	Count(63KW)	Count(50KW)	Count(30KW)
Inverters	SuunyTripower 10000Tl(SMA)	6(60.0 kW)	4(40KW)	3(30KW)
Strings	10 AWG(Copper)	12(200.8 m)	10(193.4m)	6(154.9m)
Module	REC Solar, REC280TP	255(63.0 kW)	178(49.8KW)	104(29.1KW)

3. Estimation of the energy production

The practical short circuit currentI_{sc}, and practical open circuit voltage$V_{oc}$are given as [18, 19].

$$I_{sc}(GT) = I_{sc}(STC) \times GT \quad in\ 1\ KW/m^2 \qquad (1)$$

$$V_{oc}(T_C) = V_{oc}(STC) - 0.0023 \times numberof\ cell \times (T_C - 25) \qquad (2)$$

Where (GT) is the solar irradiance, STC is a standard test conditions.
The output power (P_{out}) of the PV solar module is given by the following equation [14, 15].

$$P_{out}(GT, T_C) = I_{sc}(GT) \times V_{oc}(T_C) \qquad (3)$$

4. Energy Demand of the School

The school has 24 rooms, only 16rooms use and the others using as storage. Table 3 shows the details of the equipment and their wattage. The total daily power that required supplying by the solar system is estimated at138.4 kWh/day.

Table 3. Daily Power required

Name of equipment	No	Consumption Watt	Total Consumption kWh	Hours of operation	Total Consumption kwh/day
Air-condition	4	3000	12	8	96
Lamp	70	40	2.8	8	22.4
Fan	17	100	1.7	8	13.6
Refrigerate	4	200	0.8	8	6.4
Laptop	2	100	0.2	8	1.6
water pump	1	370	0.37	1	0.37
Server	1	15	0.015	6	0.09
Mobile charger	2	5	0.01	1	0.01
Printer Mach	2	720	1.440	1	1.440
Sum			19.335		141.91

The school is open only 168 days per year and closed for 197 days, the real demand of energy for a year is 23.848MWh/year; also the suitable connection for this system is on grid connection or hybrid connection due to the longtime of closing of schools.

5. Results and Discussion

The amount of annual incident solar irradiance with tilt angle 15° is 1964.1MWh. The monthly solar irradiance and temperature in Baghdad city as shown in Figure 5.Through the study duration in Iraqi schools (October-May) the average temperature is not hot between (10°-30°) as shown in figure 3 and therefore does not require a high cooling voltage but only lighting and fans and electric heater instead than air-condition, which does not consume so much of system power during the study season. The increase in temperature causes a decrease the power in summer with an increase in the amount of solar irradiance in same time. The increase in output power in summer months where the school is closing leads to supply the grid by the power at a peak load of energy in Iraq.

Figure 3. The monthly solar irradiance and temperature in Baghdad city.

The average loss in power due to the increasing in temperature is about 7.6%. The average of ambient temperature is 24.2°C where the average operating Cell temperature is 36.1°C during the day. Also an important source of losses in power production is the accumulation of dust and dirt on the solar panel, which about 2.0% of the production. The total loses of solar power production is 17.2%. Figure 4 illustrates all sources of energy loss in the system.

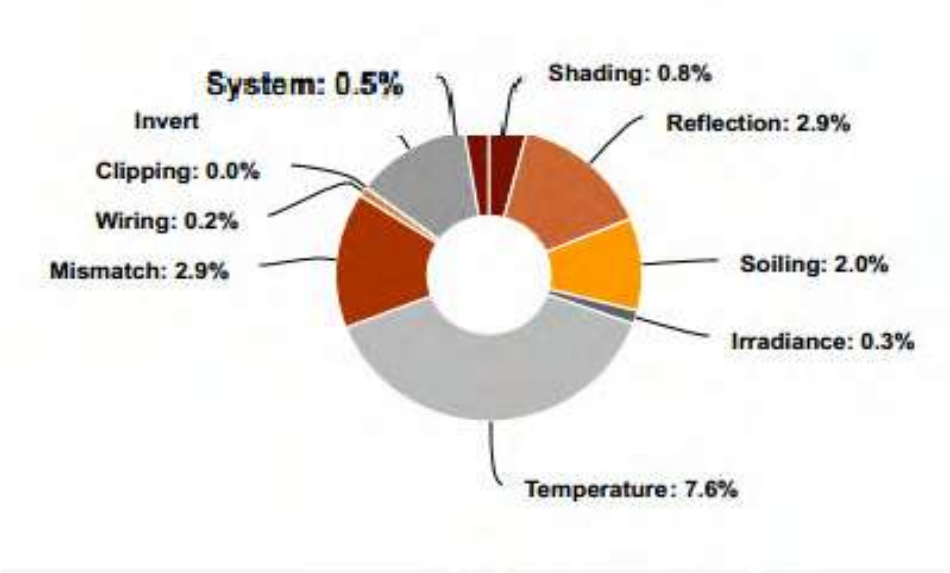


Figure 4. Sources of the system losses.

The AC power for every month for a system of 63kW, 50kW and 30kW are shown in Figures 5, 6, and 7 respectively.

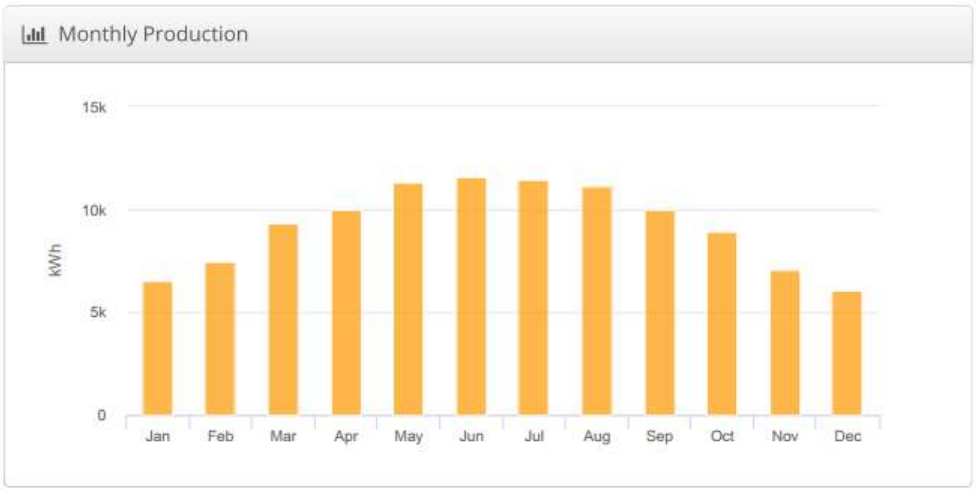

Figure 5. The AC power for every month of year for a system of 63kW.

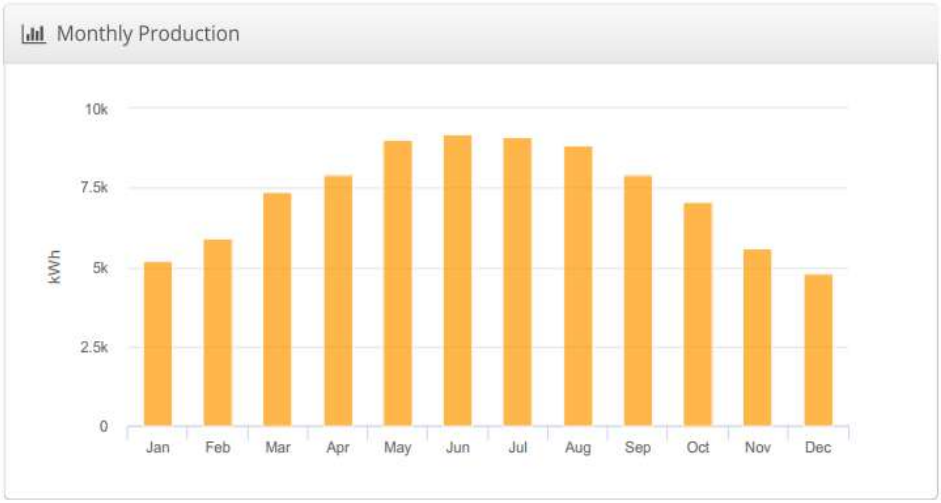

Figure 6. The AC power for every month of year for a system of 50kW.

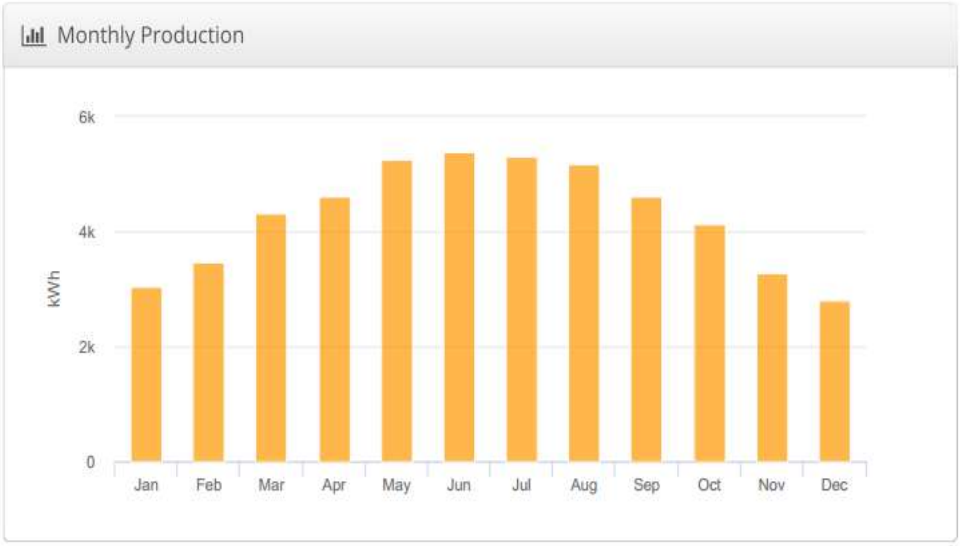

Figure 7. The AC power for every month of year for a system of 30kW.

The AC annual output power produced from systems 63 kW, 50kW and 30kW were 111.0MWh, 88MWh and 51.4 MWh respectively, with annual operating hours of 4540, 24kWh/year of them was consumed for school services and the rest were a feed of grid. In the hot summer season where the longest sunny days are actualized and due to high incident solar radiation the gain in output power was higher than the loss in power that caused by heat. The cost of establishing the solar power system (mechanical and electrical components, mechanical and electrical works) is 1$ per watt in Iraq market. The cost of the solar power systems 63kW, 50kW and 30kW were 63000$, 30000$ and 50000$ respectively. Investment of the rooftop of the school provides free space of 225m^2, 178m^2 and 104 m^2 for systems 63kW, 50kW and 30kW respectively. The price per square meter of school land is 1250$ and therefore the project cost is reduced by 281250$ (342.6%), 172500$ (345%) and 100000$ (333%) for systems of 63kW, 50kW and 30kW respectively.

The subsidized price of production power is 0.1$ per KWh in Iraq, the annual price of producing solar power in the present systems were (11100 $, 8800$ and 5140$ for systems of 63kW,

50kW and 30kW respectively. The design cost of three systems could be refunded after about (5.67) year and the solar system could work more than 25year.

By GPS program, the performance ratio for the system was 81.9%. The monthly reduction of emission of CO_2 by the production of solar power is shown in figures 8, 9 and 10 for systems 63kW, 50kW, 30kW respectively.

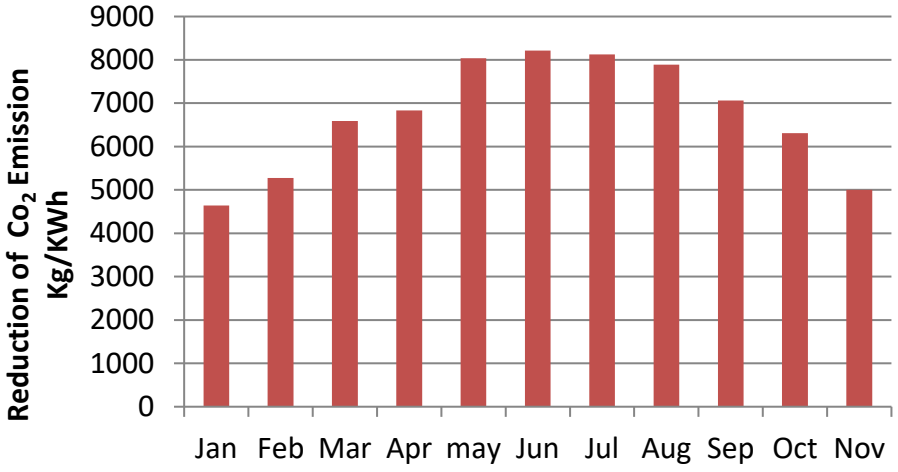

Figure 8. Reduction of emission of $CO_2$with solar power for a system of 63kW.

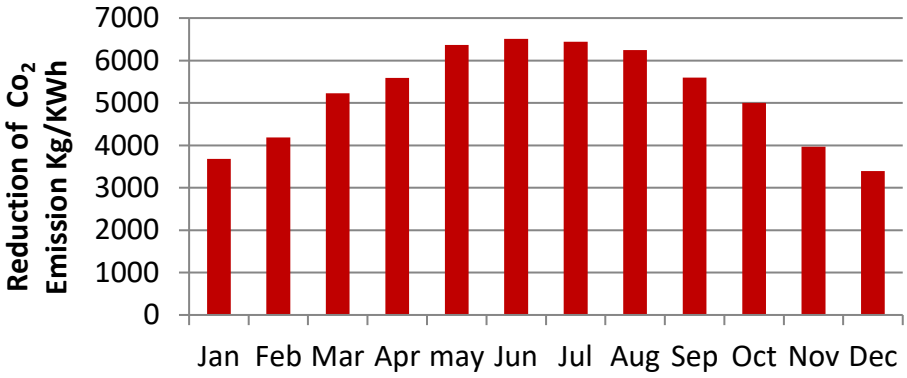

Figure 9. Reduction of emission of $CO_2$with solar power for a system of 50kW.

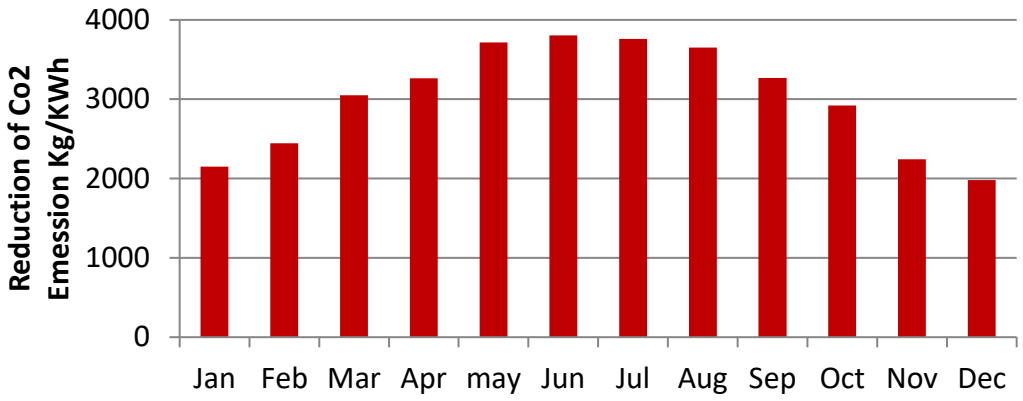

Figure 10. Reduction of emission of $CO_2$with solar power for a system of 30kW.

by using solar power instead of fossil fuel in the present system, the annual amount of emission CO^2 reduce by 73.981 tones, 62.216 tones and 36.3398 tones for systems 63kW, 50kW and 30kW respectively. The system's performance was compared with other installed PV system to have a good idea of PV solar system performance in current study as shown in Table 4.

Table 4. Performance Study Comparison of PV Systems in Different Countries

Location	Power (kWp)	Type of PV technology	Energy yield MWh/year	PR (%)	Pay back	Ref
Iran	5	Poly-crystallineSi	9.428		11.6	Korsavi et al,2018
Iraq	15	HITHeterojunction	24.08	75	-	Hisham, 2019
Iraq	5	poly-crystallineSi	9.820	82.5	5.5	Al-Khazzar, 2018
Ghana	2500	›oly-crystallineSi	3547.8	70.4	14.95	Mensah et al,2019
Iraq	63,50, 30	›oly-crystallineSi	111.0,88, 51.4	81.9	5.67	Present study

Also, the system can be a free realistic science lab for the school. This laboratory can explain the photoelectric phenomenon, semiconductors, types of (solar) battery connection, types of energy and the relationship between them and the conversion from photovoltaic to electrical and thermal energy, voltage, current, power and power, direct, alternating current, etc.

6. CONCLUSION

Iraqi environment is a benefit for green generation and it cans investment the rooftop of educational institutions to generate electric power by PV-Solar systems for these institutions and supply the grid with additional power. The localized green generation reduces transport power losses and reduces the emission of CO_2.

E-mail: randmudher13@gmail.com

Abstract. Activity concentrations of natural radionuclides, artificial radio-cesium, and soil-to-plant transfer factor in common different plants species grown at Abu-Ghraib city in the capital Baghdad have been evaluated using NaI(Tl) gamma spectroscopy. Five species of plants have been selected, namely green pepper, cucumber, celery, basil, and mint. The measurements were made on four parts of each plant sample which were included soil, roots, stalk, and leave for knowledge and evaluation the transfer factors. The maximum mean specific activity concentration of U-238 and Th-232 was 9.853±10.904 Bq/kg, 6.005±2.729Bq/kg in celery, while the maximum mean specific activity concentration of K-40 was 141.172±71.703 Bg/kg in cucumber, respectively. The results showed that the uranium, thorium, potassium and cesium concentration not exceeded the permissible limit. The mean Radium equivalent activity was 35.553 Bq\kg lower than 370 Bq\kg recommended by UNSCEAR. The maximum absorbed dose rate in root-mint samples was 30.290 nGy/h which is lower than 84 nGy/h, while the mean annual outdoor effective dose equivalent in root samples was148.597 mSv/y which is lower than 290 mSv/y recommended by UNSCEAR, respectively. The maximum H hazard index was 0.097 in root samples which is less than ≤1 recommended by UNSCEAR. The excess lifetime cancer risk (ECLR) ranged from 5.441×10^{-3} to 520.081×10^{-3}. This value is higher than recommended limit 0.29×10^{-3} and 1.16×10^{-3} reported by UNSCEAR. The ELCR is a function of environmental geology and K-40 has very high soil-to-plant transfer factor compared to other radionuclides in the samples. Therefore, there is a risk of their administration. The maximum of radioactivity level index was 0.265 Bq/kg which is less than ≤1.

Keywords: plants; transfer factor; radionuclides; hazards; cancer risk; Abu-Ghraib

1. Introduction

Natural radionuclides are found in the environment such as soil, water, air and plants, and by eating them; our bodies contain these natural radioactive materials. They usually have a low concentration of radioactivity. The natural background radiation originates from the uranium series 238, thorium 232 chain and from potassium 40, while cesium 137 originates from industrial sources [1-3]. Radionuclides are released from the soil, which is the main source of the natural background radiation. The plants will acquire these radionuclides through the roots, sticks and leaves. These radionuclides are transferred to humans by directly eating plants as food. Radionuclides that are ingested by food constitute a large part of the average dose of radiation received by the various parts of the human body, including the skeleton [4]. The dissolution of these radionuclides (uranium and thorium) in foodstuffs and inside the human

body deserves to be monitored and evaluated, and the most important thing is the naturally occurring potassium 40 as an essential component of cellular materials in all foodstuffs, where the person receives approximately 180 μSv annually from it. The average total amount of natural potassium in a normal human is about 0.14 kg, so the natural background can be considered as a constant source of human radioactivity. These have disadvantages and accumulated damage on humans that must be taken into consideration [5-6]. There are two mechanisms of plant contamination, either through absorption by roots or directly by atmospheric precipitation of radionuclides that fall on plants. So most of the radiation doses that humans receive can be considered from the consumption of food contaminated with various radionuclides, whether from natural or industrial sources, or from radioactive pollution to the environment [7-9]. That is why we found it necessary in this research to conduct an accurate assessment of radionuclides activity in plants and their transfer factor from soil to plants that are an important part of the food today used by humans and to determine the resulting risk factors.

2. Materials and methods

2.1. Collection and preparation of samples

Twenty samples of plant were collected at Abu-Ghraib city. Fifteen samples of plants and five samples of soil for each plant. Three samples parts representing (root, stalk, and leave) for each type of plants, namely cucumber, green pepper, celery, mint and basil. All samples have undergone drying, crushing, and grinding processes. Then, they were stored in tightly closed Marinelli Beckers for 30 days to achieve secular equilibrium.

2.2. Radioactivity measurement

Detection of natural radioactivity for U-238, Th-232, and K-40 in different parts of plants (cucumber, green pepper, celery, mint, basil) and soil samples were measured using sodium iodide detector technique. The standard samples were used for the calibration and the absolute efficiency of the detector as recommended by IAEA. The mixture of radionuclides with their corresponding energies are Am-163 (59.3keV), Co-60 (1173.24 and 1332.50 keV), Cs-137 (661.66 keV). The background was measured too; both were counted for two hours. U-238 activity was given by the product decay of Bi-214 (1764.5 keV). The activity of Th-232 was given by the product of Tl-208 (583.19 and 2614.5 keV). The K-40 (1460.8 keV) and Cs-137 (661.61 keV) concentrations were measured gamma lines of their energies, respectively.

3. Parameters calculation

3.1. Specific activity

The specified activity in unit Ci/kg or Bq/g is given by [10]:

$$A_i(E,\gamma) = \frac{N}{\varepsilon\,(E_\gamma)\times\ I_\gamma\,(E_\gamma)\times t\times m} \quad (1)$$

Where, N and m are the counts of area under the curve and mass of sample in kg, respectively.

3.2. Absorbed dose rate D

The outdoor absorbed dose rate can be calculated using the following formula [11, 12]:

$$D_{out}(nGyh^{-1}) = 0.427\ A_U + 0.662A_{Th} + 0.043\ A_K \quad (2)$$

Where, A_U, A_{Th} and A_K are the activity concentrations in (Bq/kg) of uranium, thorium and potassium respectively.

The indoor absorbed dose aye is given by [13]:

$$D_{in}(nGyh^{-1}) = 0.92\ A_U + 1.1A_{Th} + 0.081\ A_K \quad (3)$$

3.3. Radium equivalent Ra_{eq}

The radium equivalent activity can be expressed by [1]:

$$Ra_{eq}(Bq.kg^{-1}) = A_U + 1.43\,A_{Th} + 0.077\,A_K \quad (4)$$

The recommended limit of Ra_{eq} is 370 $Bqkg^{-1}$ given by UNSCEAR, 2000 [1].

3.4. Hazard index H

The external (H_{ex}) is given by UNSCEAR, 2000 [1]:

$$H_{ex} = \frac{A_U}{370\ Bq.kg^{-1}} + \frac{A_{Th}}{259\ Bq.kg^{-1}} + \frac{A_K}{4810\ Bq.kg^{-1}} \quad (5)$$

The internal radiation exposure is quantified by the internal hazard index (H_{in}) given by UNSCEAR, 2000 [1]:

$$H_{in} = \frac{A_U}{185\ Bq.kg^{-1}} + \frac{A_{Th}}{259\ Bq.kg^{-1}} + \frac{A_K}{4810\ Bq.kg^{-1}} \quad (6)$$

The limit of these indexes should be less or equal to unity, as reported by UNSCEAR and ICRP [1, 14].

3.5. Annual effective dose equivalent AEDE

The outdoor and indoor annual effective dose equivalents are given as the following [1]:

$$AEDE_{out}(\mu Sv/y) = D_{out}(nGy/h) \times 8760(h/y) \times 0.20 \times 0.7(Sv/Gy) \times 10^{-3} \quad (7)$$

$$AEDE_{in}(\mu Sv/y) = D_{in}(nGy/h) \times 8760(h/y) \times 0.80 \times 0.7(Sv/Gy) \times 10^{-3} \quad (8)$$

3.6. Life-time cancer risk ELCR

The excess life-time cancer risk ($ELCR$) which is given by Taskin et al. 2009 is as follows [15]:

$$ELCR_{out} = AEDE_{out} \times DL \times RF \quad (9)$$

$$ELCR_{in} = AEDE_{in} \times DL \times RF \quad (10)$$

Where; DL, and RF are the life span and risk factor respectively as given by ICRP, 2012 [16].

3.7. Annual gonadal dose equivalent AGDE

The annual gonadal dose equivalent ($AGDE$) can be calculated as follows [11]:

$$AGDE\left(\frac{\mu Sv}{y}\right) = 3.09A_U + 4.18A_{Th} + 0.314A_K \quad (11)$$

3.8. Radioactivity level index I_γ

This index is used to estimate the level of radiation risk, especially γ -rays, associated with natural radionuclides in material. It is defined as follows [17].

$$I\gamma(Bq/kg) = A_{Ra}/150 + A_{Th}/100 + A_K/1500 \leq 1 \quad (12)$$

Where A_{Ra}, $A_{Th}$and A_K are the activities of Ra-226, Th-232 and K-40 in Bq/kg respectively.

3.9. Soil-to-plant transfer factor TF

Using (IAEA) guidelines, the soil-to-plant transfer factor TF was estimated as follows [18, 19]:

$$TF = Cp\ /\ Cs \quad (13)$$

Where Cp and Cs are radionuclide concentration in plant and soil in Bq/kg respectively.

4. Results and discussion

Table 1 and Figs. 1 to 6 show the variation of activity concentrations of U-238, Th-232, K-40 and Cs-137 in green pepper, cucumber, celery, basil, mint and soil samples in Abu-Ghraib city in different parts of each sample. For the green pepper the activity concentrations of U-238 were varied from 1.504 to 12.155 to Bq/kg with an average value of 7.068±4.949 Bq/kg. Whereas, for Th-232 it was varied from 7.403 to 0.180 Bq/kg with an average value 2.909±3.424 Bq/kg. The activity concentrations of K-40 ranged from 26.570 to 76.738 Bq/kg with average value 68.633±34.272 Bq/kg, and 0.014 to 1.588 Bq/kg with an average value 0.617±0.746 Bq/kg for Cs-137. For cucumber, the results were 7.068±4.949, 2.909±3.424, 0.617±0.746, 68.633±34.272 Bq/kg. For celery, the average activity concentrations were

9.853±10.904, 6.005±2.729, 1.198±0.591, 93.320±85.462 Bq/kg. For basil, the average activity concentrations were 3.737±5.631, 4.200±2.536, 0.455±0.756, 71.687±54.966 Bq/kg. For mint, the average activity concentrations were 4.390±5.067, 8.483±6.199, 0.517±0.722 and 61.863±53.147 for U-238, Th-232, and K-40, respectively. All these values are significantly less than permissible limits (33, 45, 412, and 2.0 Bq/kg) for U-238, Th-232, K-40, and Cs-137, respectively [12, 20].

Table 1. Specific Activity Concentration for U-238, Th-232, K-40 and Cs-137 of samples, at Abu-Ghraib city.

Table 2 and Figs. 7, 8 and 9 show the calculated results of radiation hazard indices (absorbed dose, annual effective dose, annual gonadal dose equivalent (dose ingested)) respectively. The estimated average values for the outside absorbed dose rate in green pepper, cucumber, celery, basil and mint varied from 14.772 nGy/h in cucumber-root to 2.020 nGy/h in basil-leaves. However, the inside absorbed dose rate varied from 30.290 nGy/h in mint –root to 2.363 nGy/h in green pepper-leaves. It seems clear that the results are less than the worldwide permissible limits, 84 nGy/h [12]. The highest value of the annual effective dose inside and outside the body was shown in mint sample. The results of annual gonadal dose were varied from 115.655 µSv/y in mint-root to 9.139 µSv/y in green pepper-leave. All results of annual effective dose equivalent and annual gonadal dose equivalent were below the allowable limit 290 µSv/y according to UNSCEAR, 2008 [21], and below 1000 µSv/y limit, according to ICRP, 1996 [22].

Table 3 and Figs. 10, 11, 12 and 13 explain the results of the Hazard index, Life-time cancer risk, radium equivalent activity and radioactivity level index. The results show that all hazards were less than ≤1 limit [1]. The results explain that there is a variation in cancer risk. The highest life-time cancer risk, in and out of the body was found in green pepper-soil, cucumber-root, celery-root, basil-root, and mint-root. As wall, the lowest values were found in leave for each the plants. The Ra_{eq} in green pepper, cucumber, celery, basil and mint varied from 35.553 Bq/kg in mint-root to 2.137 Bq/kg in green pepper-leave. Subsequently, the highest radium equivalent was recorded in green pepper-soil, cucumber-root, celery-root, basil-soil, and mint-root while; the lowest highest radium equivalent values were in leaves of each type of plant. So, all values were less than 370 Bq/kg limit recommended by UNSCEAR, 2000 [1]. Also, Table 3 and Fig. 13 show the results of radioactivity level Index. The highest value recorded 0.265 Bq/kg in mint-root while; the lowest value was 0.019 Bq/kg in green pepper-leaves. All results of radioactivity level index were below the permitted limit 1Bq/kg [17].

As tabulated in Table 4 and illustrated in Fig. 14, the average rate of transition factor in green pepper sample of U-232, Th-232, K-40, and Cs-137 was 0.045±0.044, 0.190±0.274, 0.859±0.685 and 0.185±0.287. For cucumber sample it was 0.314±0.248, 0.604±0.271, 1.406±0.568 and0.086±0.057. With regard to celery sample was 0.704±0.418, 0.748±0.424, 0.812±0.586 and 0.673±0.410. For Basil the average rate of transform factor was 0.048±0.038, 0.423±0.226, 0.912±0.8745 and 0.048±0.032. As for mint sample was 0.102±0.052, 1.194±1.018, 0.741±0.833 and 0.101±0.089. The highest rate for transform factor was 1.194±1.018 recorded in the mint sample at a concentration of Th-232respectively. The lowest rate for the transfer from the root to the leaves was in the basil sample in Cs-137 concentration at a rate of 0.048±0.032. The results show that the highest rate of transfer factor was to the roots and the highest rate of uranium transmission was 0.983 in the celery roots sample. As well the highest transfer rate for thorium was 2.347 in mint roots while; the highest transfer rate for potassium is 1.909 to the basil roots, were comparable to those reported elsewhere. Roots won the highest transmission factor for potassium-40 which was found in most of the study samples. Extremely high K-40 transfer factor values were found in cases where the concentration of potassium was very low in soil samples. This is because of the continuous accumulations for prolonged absorption by roots of potassium-40. The mean concentrations of activity of K-40 in basil samples were greater than those in green pepper, cucumber, celery and mint and were all less than the permissible value. Finally, the highest transfer rate for Cs-137 was 1.053 in celery root.

The highest K-40 transfer factors values were concentrated in the roots and were close to the limit recommended by UNSCEAR, 2010. This high absorption i.e. uptake of K-40 by the roots, it may be due to its presence in food crops while; for U-238 differed in the average range from 0.045±0.044 in green pepper to 0.704±0.418 in celery plant. And also for Th-232 were 0.024 in the green pepper leaves to 2.247 in the root of the mint sample, with an average range of 0.190±0.274 in the green pepper plant to1.194±1.018 in mint plant. The transfer factors for Th-232 were higher than that obtained for U-238 in this study. The average soil-to-plant transfer factors for Cs-137 varied from 0.048±0.032 in basil plant to 0.673±0.410 in celery plant. These transfer factors for Cs-137 are not significant because of their low concentration in environmental samples which was obtained in this study**.**

5. Conclusions

The radioactivity was measured in samples of green pepper, cucumber, celery, basil, mint, and their soils on a regular basis. Specific activity concentrations U-238, Th-232, K-40, and Cs-137 using the NaI (Tl) gamma ray spectrum detector. To assess radiological hazards, radium-equivalent equivalents, absorbed dose rate, annual effective dose rate, hazard indices, annual gonadal dose equivalent and radioactivity level index were all estimated below the permissible limits that are considered safe from radiological hazards. In this study K-40 transfer factors were found to be arranged at the roots. Gradually, descending from the roots to the stalk and then to the leaves in the selected basil, celery and mint plants under study. Therefore, the current study proved that the samples selected under study do not have dangerous radiological effects. We recommend studying and measuring the concentrations of radionuclides and their activities in terms of availability in the local market to determine the quality of consumer foodstuffs.

Acknowledgements

The authors would like to knowledge all those contributed in declaring this work. Special thanks to the staff of nuclear physics lab. for post graduate students, College of Science, Mustansiriyah University. The authors also extend their thanks and gratitude to the employees of the Nuclear Laboratory at the College of Science, Al-Nahrain University for allowing measurements. There is no financial support for this work leading to this publication. We the authors confirm that we have not any organizations that funded our research. It is noteworthy that the transfer of radionuclides from plants to

livestock and then to humans through the food chain, may lead to many radiation hazards to the humans if the transfer factor exceed unity.

Abstract. Interest in the study of global gravitational models has increased recently all over the world because it is necessary for height datum transformations. Today the International Center for Global Earth Models (ICGEM) provides the largest collection in the world produced through gravitational data from the gravitational satellite's missions CHAMP, GRACE, and GOCE ... Etc. To allow easy access through the internet with its more intelligent technologies, it is one of the International Gravity Organization's services. While the Global Positioning System (GPS) has become one of the most preferred technologies in engineering surveying, a major dilemma in GPS survey lies in oval-based elevations. At the same time, orthometric heights are commonly used in the engineering field. Therefore, it is necessary to convert the measured heights by satellites assigned to the elliptical surface into orthometric heights and supported to the geoid surface (mean sea level) through an accurate geodetic model. The differences between orthometric measurement heights from DGPS/leveling data (obtained from 57 points in the study area) are increasingly used by professionals geographical information systems(GIS). However, the local determination of Geoid is necessary for better accuracy of the orthometric height from DGPS. This paper aims to introduce a modern technique for determining elevation, avoiding cumbersome and time-consuming spirit leveling operations. Fast vertical positioning can be obtained using DGPS with geoid models. The Root Mean Square Error (RMSE) is ± 0.19 m with high precision of DGPS derived with EGM08; thus, the more it describes the Earth's gravitational field in more detail.

Keywords: GIS, leveling, orthometric height, EGM08, Heights, Root Mean Square Error.

1. Introduction

The determination of the Earth's surface and its external gravitational field, and the normal Earth ellipsoid is the biggest issue currently confronting geodesists worldwide. The Earth's surface is uneven and, as a result, impossible to be described by a mathematical surface. Instead, Geoid, the gravitational field's equipotential surface will strongly approximate the mean sea level (M.S.L.).The Geoid is important for every country to achieve accurate vertical positioning. All geodetic measurements are directly related to gravity's real field when taken on Earth's physical surface. This anomaly area is the fundamental parameter for the transition of geodetic measurements from the physical space of observation (Geoid) to the computation's geometric space, ellipsoid [1].

To convert ellipsoid height into a more useful orthometric height, we need to know the relation between Geoid which representing the actual equipotential figure of the Earth's surface. The

ellipsoidal height represents Earth's mathematical figure. The Geoid is one of the most important parts of a geodetic infrastructure. It is well known that globally, mean sea level best fits. In the least square sense, Geoid, representing the equipotential surface of the Earth's gravity field and used as a reference for physical height system like orthometric heights. This means that by combining ellipsoidal heights from GPS and geoid heights, the orthometric height can be determined [2].

2. Study Area

The chosen study area is the campus of the University of Baghdad in the heart of the capital, Baghdad, located between Latitude (33º 16' 55.6") to (33º 16' 4.5") N, Longitude (44º 22' 11.8") to (44º 23' 20.4") E., which covers an area of (2.9km$^{2)}$. It is shown in figure (1).

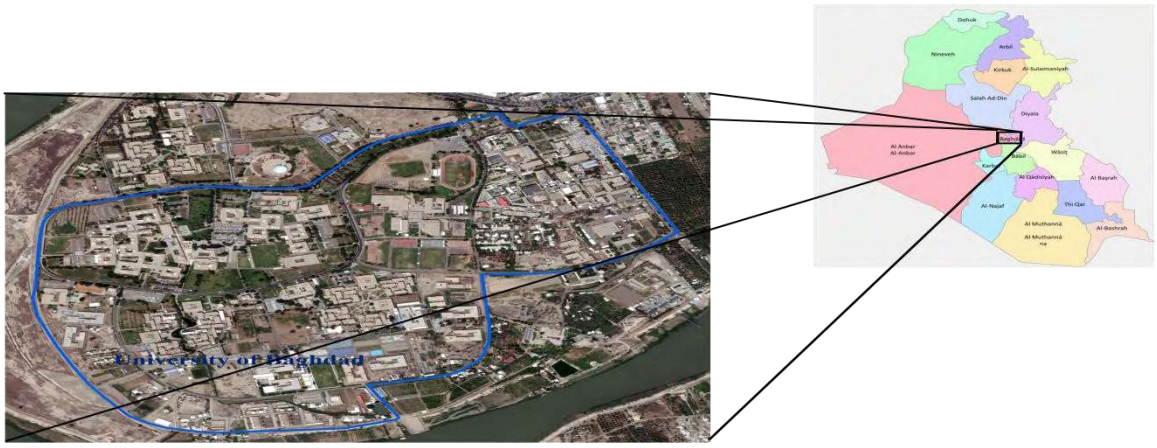

Figure 1. The study area of the campus of the University of Baghdad.

3. The Theoretical Background

3.1. The Orthometric and Ellipsoid Heights

The (H) refers to an isotope reference surface. The orthometric height of a distance from the point on the surface of the Earth to the distance that points to the Geoid (the equipotential surface that coincides with the mean sea level) is measured along the normal vertical line to the Geoid, which is measured by using the level [3]. The ellipsoidal height measured using DGPS represents the height from the surface of any reference ellipsoid to the point on the ground. The separation between the ellipsoid and the Geoid surface is called Geoid height or Geoid Undulation **(N),** as shown in figure (2). The determination of the Geoid Undulation at each point can be calculated using a well-known formula**[4]**:

$$N = h - H \quad (1)$$

h is ellipsoidal height, **H** is orthometric height, and **N** is geoid undulation

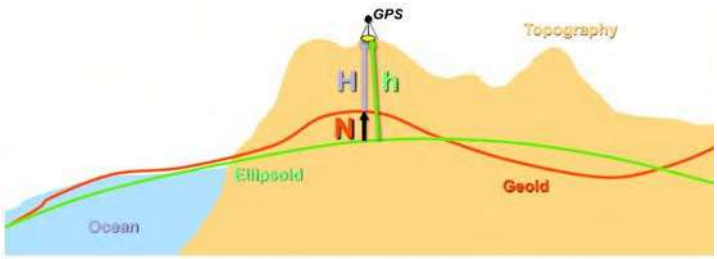

Figure 2. TheOrthometric height(H), N is the geoid undulation,[5].

3.2. Leveling

Leveling is the general term applied to any of the various processes by which height is determined. It is a vital process in producing the data needed for mapping, engineering design, and construction. Leveling results are used for designing highways, railways, canals, sewage, water supply systems, and other facilities with a grade line that best aligns with the current terrain [6]. The type of level device used in this paper is Topcon (ABN 26).

3.3. DifferentialGlobal Positioning System(DGPS)

The GPS heavenly body was initially planned as 24 satellites put in three orbital planes. Each slanted at 63 degrees as the equator chose height was *(* 20~200 *)*km, offering to ascend to an orbital time of 12 sidereal hours. This is 50% of the Earth's turn time frame, offering to ascend to rehashing ground tracks' operational advantage. These satellites were disseminated consistently in the orbital planes, with each plane having eight satellites [7].

3.4. Earth Gravitational Model of 2008 (EGM2008)

The EGM2008 is a gravitational model of the Earth created by a least-squares mix of the ITG-GRACE03S gravitational model (with its related blunder covariance lattice) and a 5'x5' matrix of free-air gravity irregularities. EGM2008 is created to degree/request 2159 with some extra terms up to degree/request 2190 [8].

EGM2008 depends on the GRACE (Gravity Recovery and Climate Experiment) just gravity field model ITG-GRACE03S which gives a profoundly exact depiction of the long-and medium-frequency gravity field range up to degree and the order 180. The ITG-GRACE03S model joins right around six years of GRACE gravity field perceptions and different wellsprings of gravity information, especially point gravity estimations. Consequently, the EGM2008 circular consonant coefficients should be extended to degree 2190 instead of 2159 or 2160 when utilized in pragmatic applications [9].

3.5. Data Sets

The orthometric heights for the 57 points were obtained from the leveling for these heights in the middle of Iraq (FAW). The datum was called MSL FAW, and this data is shown in Table 2. The differential global position system (DGPS) type Topcon Hiper-II GNSS has used a static method to observed 57 points, each point is observed 3 hours. The data points were then submitted to the AUSPOS online GPS Processing Service (HTTP: www.ga.gov.au). To calculate Geoid undulation using EGM2008, a zip file can be downloaded that contains an ESRI GRID raster data set of 2.5-minute. The American Surveying Authority worked on making Raster networks that cover all parts of the world. Each network is about 45×45 of Latitude and longitude that gives the values of N within the ready-made Raster network, and that can be called to the ARC GIS program. The network files cover lines from the length is 2 to 90, and the width from 5 to 60 covers approximately the eastern Arab world, including the Iraqi lands. The Raster can be downloaded from the link below:
https://earth-info.nga.mil/GandG/wgs84/gravitymod/egm2008/egm08_gis.html.

As shown in table (3) and Fig. (3), by cutting the province of Baghdad and noting that the value of Tthe Geoid Heights N varies from the highest [0.690 m] to the lowest [-2.910 m].

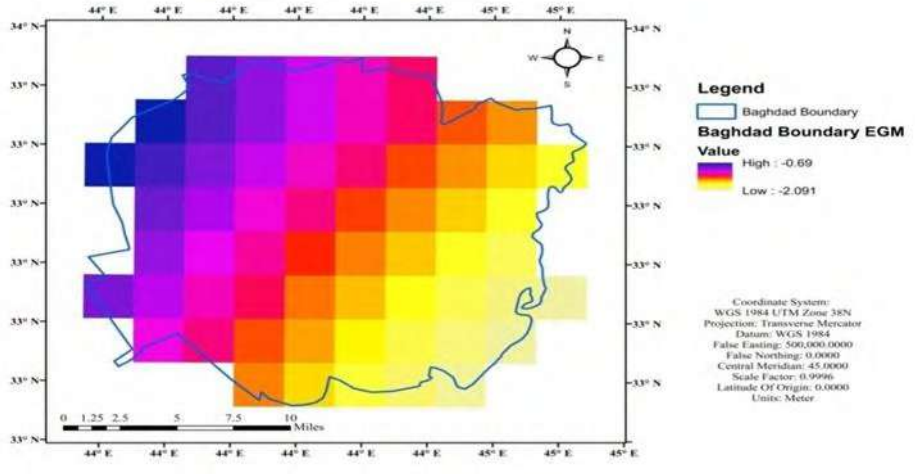

Figure 3. The Geoid HeightsEGM08 raster within the capital Baghdad.

3.6. Calculate the root mean square error (RMSE)

Modeling heights of the calendar using a geometric method of calculating model accuracy with a root mean square error indicator (RMSE) to calculate model accuracy requires orthometric point heights from the model (H_{GGMs}), i.e., orthometric heights of points obtained from the differences between typical geodetic heights and elliptical point heights with the corresponding altitudes in addition to the orthometric heights (H_{obs}) to obtain (orthometric residuals remains). The orthometric residuals and the total number of points specified for the RMSE are used along with the model accuracy. The RMSE index is provided in the formula to calculate model accuracy [8].

$$RMSE=\pm\sqrt{\frac{1}{n}\sum_{i=1}^{n}(\delta H_{Residual})^2} \quad \textbf{(2)}$$

$$\delta H_{Residual} = H_{obs} - H_{GGMs} \quad (3)$$

H_{obs}: Known Orthometric Height
H_{GGMs}: Model Orthometric Height
n: the number of points.
GGMs are the smallest RMSE values. Since then, the better it represents the Earth's gravitational field in more detail, and vice versa. The greater the value of it, the greater the representation of gravity with less detail.

4. Results and Discussion

Accuracy assessment of GPS observations processed by (EGM2008 RASTER)
The level is the most accurate way to calculate orthometric heights for scanning points above the geode .But this method has become obsolete no longer to keep pace with the rapid development in the modern world. So, it is no longer feasible for several reasons, including it takes a long time and great effort and high cost, thus, an easier, faster, and less expensive is required.
Unfortunately, GPS delivered only height relative to the Earth's mathematical ellipse, known as ellipsoidal height, rather than the orthometric height related to the MSL with its physical meaning, thus, parallel to the development of GPS and methodology.
To convert the Ellipsoid heights obtained from DGPS for the observed points into orthometric heights calculated by applying equation (1) converting the heights inside the program is required.

Table 1. The Comparison of leveling data with GPS processed data.

METHOD	Maximum (m)	Minimum (m)	Mean (m)	Standard deviation (m)
Leveling measurement height H(m)	38.264	35.930	36.653	0.586
GPS processed data	38.128	35.762	36.541	0.625
Difference	0.399	-0.401	0.111	0.152

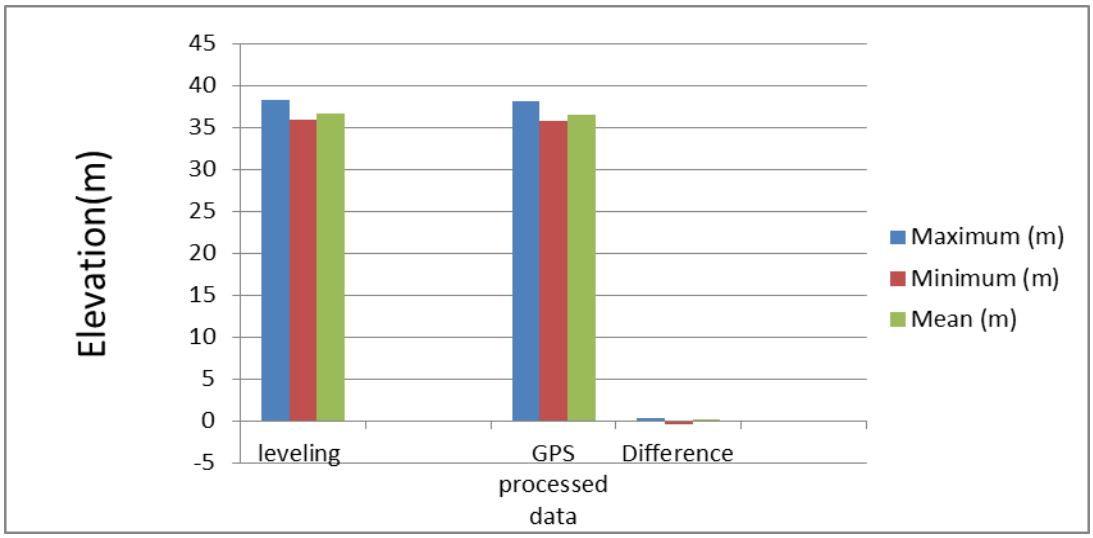

Figure 4. The Accuracy of DGPS data after processing.

The difference in leveling data with GPS processed data(HEGM08) is clearly shown that the accuracy of the results of GPS data is within the Standard deviation ±0.152m as illustrated in the table (1). The RMSE The EGM2008 model equal to [± 0.187973m] as shown in figure (4), applied the equal (3).
The height data performed herein offers useful insight for a range of applications relating to height. The production and updating of large-scale topographical maps in various engineering and construction applications, particularly for water resource management. The topographic map of the Study Area is shown in figure (5).

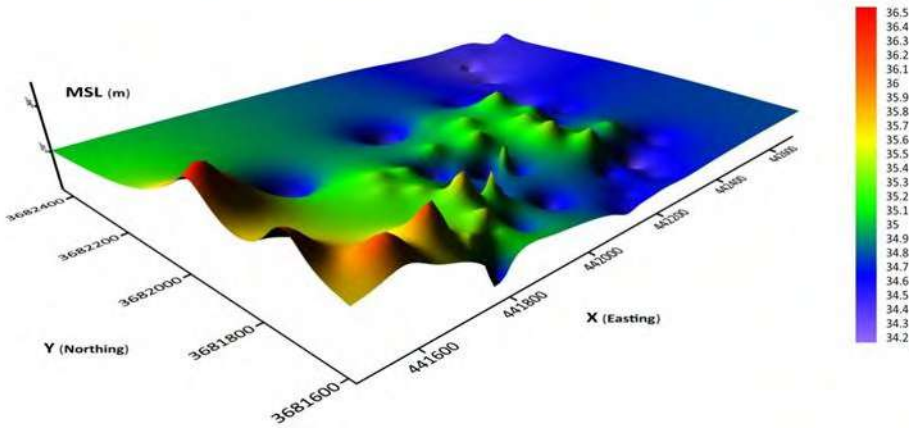

Figure 5. Representing the topographic map of the Study Area.

5. Conclusions

By comparing the data of the orthometric heights (H) values, (H) practically measured by the level with the data obtained from the after processing by the EGM2008 model, which is obtained by Raster. This study indicates small and very close differences as the accuracy reached the standard deviation (SD) equal to [± 0.152 m]. This means that the level still one of the most accurate devices in this field and in various projects.

The RMSE is used to describe the long wavelength of Earth's gravitational field. The EGM2008 model produces the smallest differences in terms of the Root Mean Square Error (RMSE), which is equal to [± 0.187973m.], and the method of the calculation by Raster is within the arc GIS program.

The orthometric Heights from DGPS Data can thus be considered a modern tool for converting the height.

Abstract. The mechanism of the electronic flow rate at Al-TiO_2 interfaces system has been studied using the postulate of electronic quantum theory. The different structural of two materials lead to suggestion the continuum energy level for Al metal and TiO_2 semiconductor. The electronic flow rate at the Al-TiO_2 complex has affected by transition energy, coupling strength and contact at the interface of two materials. The flow charge rate at Al-TiO_2 is increased by increasing coupling strength and decreasing transition energy.

Key words: Electronic Flow Rate, Al-TiO_2 and Interface.

1. Introduction

The reactions of an electronic transfer are a simple process that occurs in donor-acceptor media and it is an elementary electronic transition from an atom to atom system. It is one of the main reaction in physics devices involves oxidation-reduction state systems. It is developed since the beginning of the twentieth century [1]. Electronic transfer over distances has been investigated extensively in both experimental and theoretical studies in different inhomogeneous devices and through monolayers on the electrode system [2]. Nowadays, structure evaluations of electronics are important tools to investigate the physical properties of materials [3]. The electronic transfer due to metal/semiconductor interface has been devoted to investigate the origin of the potential barrier height at interface and effect on the electrical characteristics of this device [4]. Titanium dioxide (TiO_2) produces by low cost and higher stability and has very attractive research for mechanical, electronic and optical properties material. TiO_2 is used in many electronic applications such as adsorbents and catalytic systems [5-6]. Generally, the transition reaction at metal/semiconductor interfaces is a considerable inhomogeneous quantity of states. Therefore, the flow rate of transfer improves the performance of metallic junction devices; the transfer of electron continues across the interface above the potential junction [7]. In this work, we study the electronic flow rate at Al-TiO_2 System with coupling, electronic reorientation energies and potential coefficients. We investigate the transition rate for Al-TiO_2 structure with concerning to driving force and transition energy of the system.

2. Theory

The electronic flow rate (EFR) refers to the electronic transfer current through donor- acceptor system. It is evaluated according to quantum theory for continuum energy levels. The flow rate EFR from metal to semiconductor interface in the medium of $Al-TiO_2$ is given by [8].

$$EFR_{Al}^{TiO_2} = \frac{2\pi}{\hbar}\left|\mathfrak{M}_{Al}^{TiO_2}\right|^2 \Lambda_{Al}^{TiO_2} \quad (1)$$

Where $\left|\mathfrak{M}_{Al}^{TiO_2}\right|^2$ is squaring coupling and $\Lambda_{Al}^{TiO_2}$ is Franck–Condon factor .The Franck–Condon $\Lambda_{Al}^{TiO_2}$ can be evaluated due to perturbation approximation according to potential and can be written as [9].

$$\Lambda_{Al}^{TiO_2} = (\aleph\, \mathcal{G}_S^D)^{\frac{-1}{2}} exp - \frac{\left(\Delta\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D\right)^2}{\aleph \mathcal{G}_S^D} \quad (2)$$

Where $\mathcal{G}_S^D$ is reorientation energy, $\aleph = 4\pi k_B T$:(k_B is Boltzman constant, T is room temperature, and $\varphi_{Al}^{TiO_2}$ is activity energy). Substitute Eq,(2) in Eq.(1) and integrate over space of system gives:

$$EFR_{Al}^{TiO_2} = \frac{2\pi}{\hbar}\int_{-\infty}^{\infty}\left|\mathfrak{M}_{Al}^{TiO_2}\right|^2 (\aleph\, \mathcal{G}_S^D)^{\frac{-1}{2}} exp - \frac{\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D\right)^2}{\aleph \mathcal{G}_S^D}\, d\epsilon \quad (3)$$

Under the condition of electrons above the Fermi level due to the activity energy (E) for system is reduced : $\Delta\varphi_{Al}^{TiO_2} = \varphi_{Al}^{TiO_2} - E$, then potential must be written as [10].

$$\mathbb{V}_{Al}^{TiO_2} = \frac{\left(\Delta\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D\right)^2}{\aleph \mathcal{G}_S^D} = \frac{\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D-E\right)^2}{\aleph \mathcal{G}_S^D} \quad (4)$$

Due to continuum levels material, Eq.(3) must be formed according to density function $F_{(\epsilon)}$:

$$EFR_{Al}^{TiO_2} = \frac{2\pi}{\hbar}\int_{-\infty}^{\infty}\left|\mathfrak{M}_{Al}^{TiO_2}\right|^2 (\aleph\, \mathcal{G}_S^D)^{\frac{-1}{2}} exp - \frac{\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D-E\right)^2}{\aleph \mathcal{G}_S^D} F_{(\epsilon)} d\epsilon \quad (5)$$

Where $F_{(\epsilon)}$ is the Fermi density of electrons at Al/TiO_2 system and may be written as [11] :

$$F_{(\epsilon)} = \frac{1}{e^{\frac{\epsilon-\epsilon_F}{k_B T}}+1} \quad (6)$$

The exponential term in Eq.(5) simplified to:

$$\exp - \frac{\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D-E\right)^2}{\aleph \mathcal{G}_S^D} = \exp \frac{-\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D\right)^2+2E\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D\right)-E^2}{\aleph \mathcal{G}_S^D} \quad (7)$$

And must be approximated to:

$$\exp - \frac{\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D-E\right)^2}{\aleph \mathcal{G}_S^D} \approx \exp \frac{-\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D\right)^2}{\aleph \mathcal{G}_S^D} \exp \frac{-E^2}{\aleph \mathcal{G}_S^D} \quad (8)$$

The potential of Al/TiO_2 system interfaces at powering term in Eq.(5) can be reformed to:

$$\mathbb{V}_{Al}^{TiO_2} \approx \frac{\left(\varphi_{Al}^{TiO_2}+\mathcal{G}_S^D\right)^2}{\aleph \mathcal{G}_S^D} \approx \frac{(\chi_{Al}-\chi_{TiO_2})}{kT} \quad (9)$$

Where χ_{Al} is work function for Al and χ_{TiO_2} is electron affinity for TiO_2

Inserting Eq.(9) and (8) in Eq.(5) result [12].

$$EFR_{Al}^{TiO_2} = \frac{2\pi}{\hbar}\int_{-\infty}^{\infty}\left|\mathfrak{M}_{Al}^{TiO_2}\right|^2 (\aleph\, \mathcal{G}_S^D)^{\frac{-1}{2}} \exp - \frac{(\chi_{Al}-\chi_{TiO_2})}{kT} F_{(\epsilon)} \exp \frac{-E^2}{\aleph \mathcal{G}_S^D} d\epsilon \quad (10)$$

The Eq.(10) has reformed to:

$$EFR_{Al}^{TiO_2} \approx \frac{2\pi}{\hbar} (\aleph\, \mathcal{G}_S^D)^{\frac{-1}{2}} \exp - \frac{(\chi_{Al}-\chi_{TiO_2})}{kT} \left|\mathfrak{M}_{Al}^{TiO_2}\right|^2 \int_{-\infty}^{\infty} F_{(\epsilon)} \exp \frac{-E^2}{\aleph \mathcal{G}_S^D} d\epsilon \quad (11)$$

The integral in Eq.(11) could be solved using mathematical physics to get [13]:

$$\int_{-\infty}^{\infty} F_{(\epsilon)} \exp \frac{-E^2}{\aleph \mathcal{G}_S^D} d\epsilon \approx \left[[\pi \mathrm{k_B T} - \frac{(\pi \mathrm{k_B T})^2}{16\pi \mathcal{G}_S^D} \right] \quad (12)$$

The average of flow rate electronic current EFR is given by:

$$\overline{EFR_{Al}^{TiO_2}} = \frac{V_{TiO_2}}{n} EFR_{Al}^{TiO_2} \quad (13)$$

Then Eq.(12) with Eq.(13) becomes:

$$\overline{EFR_{Al}^{TiO_2}} \approx \frac{2\pi V_{TiO_2}}{\hbar} (\aleph \mathcal{G}_S^D)^{\frac{-1}{2}} \exp - \frac{(\chi_{Al} - \chi_{TiO_2})}{kT} \left| \mathfrak{M}_{Al}^{TiO_2} \right|^2 \left[[\pi \mathrm{k_B T} - \frac{(\pi \mathrm{k_B T})^2}{16\pi \mathcal{G}_S^D} \right] \quad (14)$$

The electronic reorientation energies for Al/TiO_2 system is [14]

$$\mathcal{G}_S^D(eV) = \frac{e^2}{8\pi\epsilon_\circ} \left[\frac{1}{2R_{Al}} \mathbb{f}(n_{Al}^2, \epsilon_{Al}) + \frac{1}{2R_{TiO_2}} \mathbb{f}(n_{TiO_2}^2, \epsilon_{TiO_2}) - \frac{1}{4D_{TiO_2}} \mathbb{f}(n_{Al}^2, n_{TiO_2}^2 \epsilon_{Al}, \epsilon_{TiO_2}) - \frac{1}{4D_{Al}} \mathbb{f}(n_{TiO_2}^2, n_{Al}^2, \epsilon_{TiO_2}, \epsilon_{Al}) \frac{1}{d_{Al-TiO_2}} \mathbb{f}(n_{Al}^2 + n_{TiO_2}^2 \epsilon_{Al} + \epsilon_{TiO_2}) \right] \quad (15)$$

Where e is electronic charge, $\epsilon_\circ$ is space permittivity, $\mathbb{f}(n_1{}^2, \epsilon_1) = \left(\frac{1}{n_1{}^2} - \frac{1}{\epsilon_1}\right)$ and $\mathbb{f}(n_1^2, n_2^2 \epsilon_1, \epsilon_2) = \left(\frac{n_2^2 - n_1{}^2}{n_2^2 + n_1{}^2} \frac{1}{n_1{}^2} - \frac{\epsilon_2 - \epsilon_1}{\epsilon_2 + \epsilon_1} \frac{1}{\epsilon_2}\right)$ are the polarity function of two material system respectively, n_1 and ϵ_1 are the refractive index and dielectric constant of metal(Al), n_2 and ϵ_2 are the refractive index and dielectric constant of TiO_2, R_{Al} is Aluminum radius, and d_{Al-TiO_2} is the distance between TiO_2 and Al. Then the radii of any material estimates are [15]:

$$R_{mat} = \left(\frac{3}{4\pi} \frac{M_{mat}}{N \rho_{mat}}\right)^{\frac{1}{3}} \quad (16)$$

Where M_{mater} is the molecular weight, N is Avogadro's number, and ρ_{mater} is the mater density.

3. Results and discussion

The electric flow rate has been estimated by using a simple numerical model for transfer in Al-TiO_2 system ,it has been discussed and predicted by experimental results .It assesses to explained the effect of transition energy parameters on the performance of transfer in metal-semiconductor interfaces. The performance of transfer can be discussed in terms of electronic flow rate of the device. In order to evaluate the transition flow rate, we can estimate the transition energy according to Eq (15) with the estimation of the radii of Al and TiO_2 using Eq.(16) by inserting atomic density and molecular weight from Tables 1 and 2 of Al and TiO_2 material and resulted in Tables 1 and 2, respectively .

Table 1. Properties of Al Metal.

Properties	Values
Atomic weight	26.982 [16]
Crystal structure	cubic
Lattice constant (nm)	0.405 [17]
Dielectric constant	1.6-1.8
Refractive index	0. 2 to 1. 20 [18]
Density (g/cm^3)	2.70 [16]
Work function	4.05 [19]
Calculated radius (nm)	0.143

Table 2. Characteristic of TiO_2 semiconductor.

Properties	Values
Chemical Formula	TiO_2
Atomic weight	79.866 [20]
Density (g/cm3)	4.23[20]
Crystal structure	Tetragonal rutile[20]
Melting point (ºC)	1843°C[20]
Refractive index	2.609[20]
Dielectric constant	15.10 [21]
Volume (Å3)	62.432[22]
Energy gap (eV) at 300K	3.02[22]
Lattice constant (Å)	a=4.5936 c =2.9587[22]
Electron affinity (eV)	4.2[22]
Calculated Radius(Å)	1.95612
Effective density of states in conduction band, N_C m^{-3})	1.163×10^{25}[4]

The transition energy is calculated using the values of primary input refractive index and dielectric constant and radii of Al and TiO_2 parameters which are listed in Tables 1 and 2 and inserting in Eq.(15). The results are listed in Table 3.

Table 3. Results of transition energy for Al-TiO_2 system.

Refractive index(n_{Al})	Dielectric constant(ϵ_{Al})	Transition energy $\mathcal{G}_S^D(eV)$	Refractive index(n_{Al})	Dielectric constant(ϵ_{Al})	Transition energy $\mathcal{G}_S^D(eV)$
0.2	1.8	43.5806	0.2	1.6	43.4568
0.4	1.8	10.2653	0.4	1.6	10.1415
0.6	1.8	4.0937	0.6	1.6	3.9699
0.8	1.8	1.9315	0.8	1.6	1.8077
1	1.8	0.9285	1	1.6	0.8047
1.2	1.8	0.3817	1.2	1.6	0.2579

From Table 3, it can be seen that the transition energy decreased with increasing the refractive index and stable dielectric constant for the same Al metal. It also increases with increasing the dielectric constant of Al metal for same refractive index and dielectric constant for TiO_2 semiconductor. It means that energy as a function of the polarity of Al metal dependent on energy absorption by the system because the refractive index depends on energy.

On the other hand, Eq. (14) outlined in theory can be applied to calculate and studied the electron transfer flow rate in Al-TiO_2 system. To investigate the electronic transfer cross interface of Al-TiO_2 using quantum theory, we have considered continuum energy levels for two materials. All parameters of Al metal and TiO_2 are taken from Tables 1, 2 and 3 and take the strength coupling from literature

$\mathfrak{M}_{Al}^{TiO_2} = 4\times10^{-2}, 8\times10^{-2}, 12\times10^{-3}, 16\times10^{-3}, 2\times10^{-4}\ \ eV^2 state^{-1}$ [24] ,and input in Eq.(14) to result of flow rate that is listed in Tables 4 and 5 for dielectric constant of Al metal ϵ_{Al}=1.8 and 1.6, respectively.

Table 4. Electronic Flow Rate at Al-TiO_2 Interfaces System with dialectic constant ϵ_{Al}=1.8.

0.8047	8.0784E-12	1.6157E-11	2.4235E-12	3.2314E-12	4.0392E-14
0.2579	4.5048E-12	9.0096E-12	1.3514E-12	1.8019E-12	2.2524E-14

In order to show the effect of polarity of metal, we take two different dielectric constants for Al metal. Tables 4 and 5 show that the flow rate increased with decreasing of transition energy for two dielectric constant 1.8 and 1.6 respectively, in a way that flow rate increases with coupling strength for two Tables 4 and 5; this indicates that the energy levels for two materials must be closed to each other with high electrons concentration closed interface of the system. Similar behaviors of flow rate in Table 4 and 5 at dielectric constant with ϵ_{Al}=1.8 and 1.6 indicate that the structure and properties of Al metal is important effect on the behavior of flow rate of system. Specifically, we have considered the same properties of TiO_2 semiconductor with Al metal to avoid the effects of polarity of TiO_2 on the flow rate .However; the results were obtained from two tables (4-5) which show that flow rate increased with decreasing dielectric constant of Al metal.

4. Conclusion

In this study, we first conclude that the transition energy is a function of the refractive index of Al, and it decreased with increasing refractive index and increased with increasing the dielectric constant of Al metal with constant refractive index and dielectric constant for TiO_2 semiconductor. In fact we can conclude that transition energy is a function of polarity of Al metal. The Al-TiO_2 devices exhibit a continuous transition of electrons across the interface; the flow rate increased with decreasing of transition energy and increased of coupling strength. Here, we assumed continuum energy levels for

Al and TiO_2 material to direct transfer over closed space for two materials with high electrons concentration near interface of system. Aggregation, the transition energy and contact at interface with coupling strength coupling of Al metal with TiO_2 surface are key factors affected on the quantity of electronic flow rate.

E-mail: draqeelrsalih@gmail.com

Abstract. In this paper, a step-index fiber with core index 1.445517 and cladding index 1.443157 has been designed and studied. Multimode operation is achieved by using a fiber with core radius 25 μm operating at a wavelength of 1.3 μm. The mode parameters (effective refractive index, phase constant, fractional modal power in the core and cutoff wavelength) were calculated using RP fiber calculator (PRO version 2020). The shapes of the intensity and amplitude distribution of linearly polarized guided modes were shown.

Keywords: Fiber design, Step-index fiber, Multimode fiber, Linearly polarized modes, RP Fiber calculator.

1. Introduction

An optical fiber, which acts as the transmission channel, lies at the heart of an optical communication system [1]. A step-index fiber (SIF) consists of a core with a refractive index n_{core} that is slightly higher than that of the cladding, n_{clad} [2]. Most of the fibers are made from silica glass [3] which can be doped with (e.g., germanium or phosphorus) to increase the refractive index or with (e.g., fluorine or boron) to decrease it [4]. Fibers that support multiple guided modes (LP_{lm} modes) are called multimode fibers (MMFs) [5]. Typically, the core radius is around 25 μm for MMFs. The three lowest-order guided modes are illustrated in **Figure 1.**

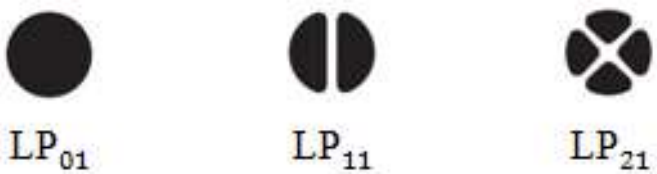

Figure 1. Intensity profiles for the three lowest linearly polarized (LP) modes [6].

In 1966, Kao and Hockham [7] proposed that glass fibers could be a practical optical transmission medium. They predicted that fiber loss could be reduced below 20 dB/km. The fiber process advanced very quickly after the demonstration of fiber with a loss of about 17 dB/km at a wavelength of 0.633 μm in 1970 [8]. By 1973, the loss of less than 5 dB/km at 0.85 μm was reported [9]. In 1976, the loss of 0.47 dB/km was reported at 1.2 μm [10]. In the late 1970s through the early 1980s, the

telecommunication systems used MMFs along with light emitting diodes (LEDs) or laser transmitters at 0.85 μm and 1.3 μm [4]. In 1988, the first transatlantic fiber cable was made operative at 1.3 μm. By 1996, data transmission at 1 Terabit/second was realized [11, 12]. In 2001, it has been possible to send about 11 Terabit/second through optical fiber [13]. In 2009, Kao received the Nobel prize for his work on fiber optics [14]. In 2018, successful transmission of 1.2 Petabit/second has been achieved [15, 16]. In my previous work [17], a single-mode SIF is designed at 1.31 μm and 1.55 μm. In this work, a MM SIF has been designed at 1.3 μm.

2. Theoretical Background

The *V* number gathers all of the design parameters characterizing the optical fiber. It is given by [18]:

$$V = \frac{2\pi}{\lambda} r \sqrt{n_{\text{core}}^2 - n_{\text{clad}}^2} \tag{1}$$

where r is the core radius and λ is the vacuum wavelength of operation. Fiber dispersion is the lowest at 1.3 μm wavelength. The *V* number determines:
The number of guided modes. If $V > 2.4048$ the fiber will be MM.
The fraction of power guided inside the core.
The phase constant for some wavelength is the effective refractive index (n_{eff}) times the vacuum wavenumber [5]. Guided modes occur if $n_{\text{clad}} < n_{\text{eff}} < n_{\text{core}}$. Modes with $n_{\text{eff}} < n_{\text{clad}}$ are called radiation modes. No mode exists when $n_{\text{eff}} > n_{\text{core}}$ [3].
The normalized phase constant is defined by:

$$b = \frac{n_{\text{eff}}^2 - n_{\text{clad}}^2}{n_{\text{core}}^2 - n_{\text{clad}}^2} \tag{2}$$

For guided modes, $0 < b < 1$.
The allowed discrete values of b of the guided LP_{lm} modes are determined by the transcendental equations:

$$U\frac{J_1(U)}{J_0(U)} = W\frac{K_1(W)}{K_0(W)}, \qquad l = 0 \tag{3}$$

$$U\frac{J_{l-1}(U)}{J_l(U)} = -W\frac{K_{l-1}(W)}{K_l(W)}, \qquad l \geq 1 \tag{4}$$

where $U = V\sqrt{1-b}$ and $W = V\sqrt{b}$. Here $J_l(U)$ and $K_l(W)$ are the Bessel functions of order l.
There will be a finite number of solutions of Equations (3) and (4) for a given value of l, and the mth solution ($m = 1, 2, 3, \ldots$) is referred to as the LP_{lm} mode.
The value of V at which $b = 0$ is known as the cutoff value (V_c) of the mode. The cutoff *V* values are tabulated in Table 1.

Table 1. Cutoff *V* values for the LP_{lm} modes [19].

l	m		
	1	2	3
0	0	3.8317	7.0156
1	2.4048	5.5201	8.6537
2	3.8317	7.0156	
3	5.1356	8.4172	
4	6.3802	9.7610	
5	7.5883		
6	8.7715		

The cutoff wavelength (λ_c) of the mode is the wavelength where that mode ceases to exist [5]. It can be calculated from [2]:

$$\lambda_c = \frac{2\pi}{V_c} r \sqrt{n_{\text{core}}^2 - n_{\text{clad}}^2} \quad (5)$$

The range of wavelengths over which LP_{lm} mode will propagate is $0 < \lambda < \lambda_c$.
From Equations (1) and (5),

$$\lambda V = \lambda_c V_c \quad (6)$$

A quantity of interest for SIFs is the fractional power carried in the core. It is given by [20]:

$$\frac{P_{\text{core}}}{P_{\text{total}}} = \frac{W^2}{V^2} + \frac{U^2}{V^2} \frac{K_l^2(W)}{K_{l+1}(W) K_{l-1}(W)} \quad (7)$$

3. Results and Discussion

In this work, a SIF characterized by the parameters in Table 2 has been designed. It operates at a wavelength of 1.3 μm as a multimode fiber.

Table 2. Parameters of the fiber.

n_{core}	1.445517
n_{clad}	1.443157
r	25 μm
V **at** λ **=1.3 μm**	9.9766

One finds that there are three modes each corresponding to $l = 0$ and $l = 1$, two modes each corresponding to $l = 2, l = 3$ and $l = 4$, and one mode each corresponding to $l = 5$ and $l = 6$. The mode properties (Tables 3 to 6) were calculated by using RP Fiber Calculator software (PRO version 2020). From these tables, it can be noted that:
All values decrease with increasing l, m indices of the LP_{lm} modes.
The fundamental LP_{01} mode is the one with the highest values.
Effective indices lie between core and cladding indices.
For any mode, the phase constant is the effective index multiplied by the free space wavenumber.
Far from cutoff value, the modal power is concentrated in the core.

4	2.02445	1.32325	
5	1.70215		
6	1.47258		

Cutoff wavelengths calculated from Equation (5) are listed in Table 7. These values are in good agreement with those in Table 6. Unlike other modes, the LP_{01} mode has no cutoff ($V_c = 0$). The cutoff wavelengths of LP_{21} and LP_{02} modes are the same (because the cutoff values are the same). Also, the cutoff wavelengths of LP_{22} and LP_{03} modes are the same. Cutoff wavelengths are larger than the operating wavelength (because the *V* number is larger than the cutoff values). If cutoff value for a particular guided mode approaches *V* number, then the cutoff wavelength will be close to the operating wavelength.

Figures 2 to 4 show 2D mode profiles and plots of the radial dependence. These figures have been produced with the software RP Fiber Calculator. The modes profiles have increasing complexity as their indices are increased. The three lowest-order modes are similar to those illustrated in **Figure 1.** The intensity distribution of the lowest-order mode (LP_{01}) is circularly symmetric. The LP_{11} mode has two lobes oriented left and right. The higher-order modes have multilobed patterns, with $2l$ maxima in the angular direction and m maxima in the radial direction. In each profile, the thin circle locates the

core boundary. The amplitude distribution can be obtained from the intensity distribution by taking the square root. It can be seen that only LP_{0m} modes have a profile having a peak in the center of the fiber core. While, the other modes have a peak away from the center.

4. Conclusions

Using RP Fiber Calculator program, it is possible to calculate cutoff wavelengths and other properties of modes. It is shown that if the operating wavelength is less than the cutoff wavelength, the fiber will be multimoded. The further away a mode is from its cutoff value the more concentrated its power is in the core. This fiber is candidate for practical use because most guided modes have fractional core powers of over 90%.

Abstract. This study was aimed to evaluate the effect of chitosan nanoparticles loaded oxytetracycline hydrochloride on health status, and survival rate of common carp infected with Columnaris disease. A total 160 fish of Cyprinuscarpio L. weighed between 48-50g were randomly distributed into eight treatments, and 48 fish were used to determine LD50. (Two replications for each treatment).The bacterial concentration of F. column are that used for infection test after a serial dilution was 0.2ml (1.8 × 106 CFU/ml), then removal a few of scales near the caudal fin and injection subcutaneously. The trial injected fish treated by ordinary oxytetracycline hydrochloride as T0 in dose 20 mg /L and T1, T2, T3, T4 and T5 treated by chitosan nanoparticles loaded oxytetracycline hydrochloride in dose 20, 15, 10, 5, 2.5 mg/L respectively. The control (+) infected without gave treatment, whilst, control- was no infected. All the treatments gave the bath treatment 1-hour per-day for 7 days, clinical signs post treatment were evaluated also, RBC counts, WBC counts, PCV, Hb, Total proteins, Albumin, Globulin, A/G ratio and survival rate were measured. One week after the end of the treatment period, an improvement in health and feed consumption was observed in T4 and T3. The results revealed significant increases ($P<0.05$) in PCV, Hb, RBCs count and WBCcount of C. carpio post-treatment in treated groups T4 (26.46%, 8.95 g/dl and 2.27 cell×106/mm3 and22.10 cell×103/mm3respectively) compared with control (+) (15.95%, 5.94 g/dl,1.55 cell×106/mm3 and19.13 cell×103/mm3respectively).In addition, Total proteins, Albumin, Globulin showed significant increase ($P< 0.05$) in T2, T3, T4, T5 comparison with the control+ group and highest values were recorded in T4. While, The result of A/G ratio revealed a significantly decreased ($P>0.05$) in all treatments in compared with Control(-) and no significant difference ($P > 0.05$) compared with Control(+).The best A/G ratio recorded in T4 and T5.In addition, survival rate 90% recorded as the highest value in T4. This current administration technique of oxytetracycline, proved to become much more efficient with respect to conventional exposure and has the potential to minimize the usage of antibiotics in fish farms and regarding environmental effects.

Keywords: chitosan, nanoparticles loaded, oxytetracycline, health status, common carp, columnaris

1. Introduction

Common carp (Cyprinus Carpio L.) is known to be the most important aquaculture fish in many Asian and European countries (Mohammad, 2015). It is introduced into Iraq as a breeding fish and transmitted among all Iraqi water bodies since it is living in different environmental conditions, has the fastest growth at water temperatures around 23-30 C, survives in cold winter, tolerates salinity of

12 g / L (Al-Hamed, 1971; Al-Rudainy et al., 2008). The production of fish farming causing massive economic losses each year worldwide is regarded as being considerably limited by the outbreak of disease (Austin, 2007). The infections of bacterial are a major impendence to economic viability for any aquaculture farming (Yousefian et al., 2009). Fish are sensitive to a wide range of infectious bacteria causing a high mortality rate in fish culture (El- Sayyad et al., 2010). Columnaris disease is one of the most common infectious bacterial diseases of freshwater fishes infecting both cultured and wild fish species. It has a huge economic effect on fish farming due to the increased and rapid mortality rates of it creates. (Marshet, 2018). Flavobacterium columnare is a widely available bacterium in aquatic ponds as well as a causative agent of Columnaris disease in fine fish. Flavobacterium columnare has also been recognised as a global bacterium for fish species (Figueiredo et al, 2005).

The administration of antibiotics, for many years, was the generality common method for handling the occurrence of bacterial infection in the aquatic ecosystem. However, dangerous problems still face the aquaculture because of adverse results of those drugs like accumulate in the tissue of creatures, immunosuppressant, development of bacteria to resistant antibiotic and ruin of environmental microbial flora (Baulny et al., 1996).Due to the increase in the outbreak of bacterial diseases in the aquaculture industry and the development of bacterial resistance, new antibacterial agents are required (Gong et al., 2007; Soltani et al., 2009). The nanoparticles have been used to deliver the drugs into the cells with negligible side effects (Scott, 2005). , chitosan nanoparticles and PLGA nanoparticles are being tested as nanoparticles for drug delivery in fish medicine. (Wang, 2011). Chitosan is a mucopoly saccharide that is closely related to cellulose. It is a derivative of chitin and is formed by chitin deacetylation. (Soutter, 2013: Crini, 2019).

Chitosan nanoparticles were used to boost their transfer efficiency in cells as drug carriers and gene carriers, as recorded in many researchers (Chopra et al., 2014; Csaba and Alonso, 2014). In the Fish culturists notified that the oxytetracycline-hydrochloric acid bath handlings were, efficient in decreasing mortality in freshwater fish diseased with F. columnare (Stehly 2002). Oxytetracycline-hydrochloric successfully minimize the mortality in walleyes (10 mg/L only) and channel catfish infected with Columnaris (Rach et al., 2008). The synthesis of antibiotic conjugates with biopolymers is a relatively new trend of research that generally has the purpose of prolongation the antibiotic action and decreasing its toxicity (Ueda et al., 1989).

In this current study explained the effect of chitosan nanoparticles loaded with oxytetracycline on some blood parameters and health status of carp fish with columnaris disease in comparison with conventional oxytetracycline hydrochloride therapy.

2. Materials and Methods

2.1. Materials

Chitosan, sodium tripolyphosphate, phosphate-buffered saline**,** acetic acid**,** Cytophaga Agar, De-ionized water Oxytetracycline hydrochloride (purity 99%) and distilled water. All other chemicals were obtained from commercially from AL-Bashir Scientific Bureau/Iraq. *Flavobacterium columnare* isolate were taken from Department of Pathology/Fish Diseases College of Veterinary Medicine/Baghdad University.

2.2. *Flavobacterium columnare*

Isolate of *F. columnare* bacteria was taken from "Department of fish diseases College of Veterinary Medicine/Baghdad University", the bacteria was a three-time passage into a stable common carp to improve bacterial virulence. Then, all biochemical tests were done to ensure the characteristics of the bacteria.

2.3. Preparation and loaded the chitosan nanoparticles

The chitosan nanoparticles were synthesized from the chitosan via sodium tripolyphosphate as a cross-linking agent by ionotropic gelation method (Vimal *et al*, 2013).About 1.5 g of chitosan dissolved in 200 ml of 2% acetic acid, this solution was placed for about 20 minutes under the magnetic stirrer process. Next to the above-Initialized chitosan solution, (0.8 g) of sodium tripolyphosphate dissolved in (107 ml) of conductivity water were added drop wise. Then stirred well enough to reach equilibrium for around 30 minutes. A milky colored emulsion of chitosan nanoparticles appears, which was formed upon the ionic cross-linking between the sodium tripolyphosphate and chitosan solution. After achieving equilibrium, the suspension was established in the conditions mentioned above.
Oxytetracycline hydrochloride melted in distilled water was added to the ChNPs solution in the ratio of 1:1, under stirring for twenty-minute. In addition, this suspension then was left under ultra-sonication for 45 minutes. After that lastly stirring for another, twenty minutes, to gain a final concentration of antibiotics 3.75 mg/ml (Du et al., 2009; Jain and Banerjee, 2008).

2.4. Experimental Design

This research was carried out at the (College of Veterinary Medicine of Baghdad, an Ichthyology laboratory). A total of 160 healthy carp fish selected and treated by the formalin at the concentration of (25ml/200L) water used for ten min to annihilate the fungal, bacterial, and parasitic infections. After that distributed into 16 glass aquaria filled with chlorine-free tap water and supplied with an air pump at a rate of 10 fish per aquarium (two replicates treatment) were maintained for each of the 7 treatments (T0, T1, T2, T3, T4, T5, Control(-) and Control (+). Then, 2 weeks of fish adaptation until beginning the experiment, and feeding on a commercial diet, at a rate of 2% of their body weight.
The bacterial concentration of *F. columnare* that used for infection test after a serial dilution was 0.2ml (1.8×10^6 CFU/ml), then removal a few of scales near the caudal fin and injection subcutaneously. In this experiment some of infected did not eat feed and to ensure that all fish are treated, the immersion bath was used for treatment according to researchers (Jeff *et al* 2008; Julinta *et al* 2017). The trial injected fish treated by ordinary oxytetracycline hydrochloride as T0 in dose 20 mg /L and T1, T2, T3, T4 and T5 treated by chitosan nanoparticles loaded oxytetracycline hydrochloride in dose 20, 15, 10, 5, 2.5 mg/L respectively.

All the treatments given the bath treatment 1-hour per-day for 7 days, mortality was already recorded daily for up to 14 days throughout all treatments, and assessment of survival rate after 7 days of treatment end, bacteria recovered from blood and kidney of the experimental challenge fish were identified as *F. columnare* after re-isolated it. In all treatments, live and dead fish were examined for abnormal behaviours' including movement, swimming and external lesions on the skin and gills. At the final of the experimental procedure, the fish were counted according to (Amend, 1981) to assess the survival rate.

$$\text{Survival rate \%} = \frac{\text{No. of fish counted after 7days post-treatment end}}{\text{No. of total fish counted at the initial time}} \times 100$$

2.5. Blood collection and sample preparation

Blood samples were collected using 3 ml plastic syringe (G 23 da). Three randomly selected fish were picked per aquarium from caudal vessels. To prevent any blood clot, the syringe was flushed with heparin. No anaesthetic medications have been used to avoid any possible effect on blood content, and the handling time was less than 1 minute to reduce the stress. The first part of the blood was transferred to lithium-heparin coated sterile Eppendorf tubes, which are used to measure blood haematology.

The second part was transferred to the gelatin-containing Eppendorf tubes and permitted to clot for 2 hours. Serum was already separated via centrifugation, store at-20°C that can be used for biochemical parameters (Albumin, Globulin and Albumin/Globulin Ratio).

2.6. Determination of Haematological Parameters:

2.6.1. Determination of Total Erythrocytes and Leukocytes Counts:

The total of erythrocyte and leukocyte count through diluted 20 µl of the freshly obtained blood sample with (0.98 ml) of Dacie solution. (10ml of 40% formaldehyde, 31.3g trisodium citrate, 1.0 g brilliant crystal blue dissolved in one L of distilled water and filtered through 0.45 µm syringe filter). Counts were performed on an improved hemocytometer of Neubauer. A drop in the hemocytometer was dripped, five squares were used to count the number of red blood cells (Dacie and Lewis, 1984). The followed equation was applied:
Total RBCs (Erythrocyte / µL6) = N (number of cell) x 2500

WBC's were counted in four squares (four corner squares) (Dacie and Lewis, 1984). The following equation was applied:
Total WBCs (Leukocyte / µL3) = N (number of cell) x 125

2.6.2. Packed Cell Volume (PCV %)

Haematocrit (packed cell volume) of total blood was calculated using the capillary system, the heparinized blood was drawn by heparinized capillary tube and one of its ends blocked with sealing material. Next separated using a haematocrit centrifuge (5000 round/min for 5 minutes, following centrifugation, the total percentage of PCV was determined with haematocrit reader (Thrall *et al*., 2006)**.**

2.6.3. Haemoglobin (Hb) content

The cyanomethemoglobin process (Blaxhall and Daisley, 1973) was used to assess haemoglobin amounts (Hb). By using haemoglobin kit, the haemoglobin reaction with cyanide was dependent upon for the formation of cyanomethemoglobin. The test tube administered with 20 µl non-coagulant blood that had been freshly obtained, applied to the 5 ml diluents mix (Drabkin's reagent), and left at room temperature for 5-10 minutes (25°C).Absorbance or optical density (O.D) was measured using a spectrophotometer at 540 nm The Drabkin Diluents reactant (1.0 g of sodium bicarbonate, 50 mg of potassium cyanide, 200 mg of potassium ferricyanide, dissolved in 1L water), was a stock of cyanomethemaglobalin as normal, distilled into a multi-dilutant (Dacie and Lewis, 1995).

3. Results

3.1. Treatment and Survival rate of C. carpio:

Following the carp fish injected with *F. columnare,* the treatment of the infected fish was started when mortality appeared in the fourth day after bacterial injection. All the treatments are given the treatment 1-hour per-day for 7 days; mortality was recorded daily up to 14 days in the all groups and recording the survival rate after 7 days of treatment end, and observe the clinical signs of treated carp fish daily after the end of treatment. The results revealed a clear increase in survival rate in T4 that were 90% and T3 were 70% followed by T5 and T2 which give the same percentage 55% .while, T1 was recorded the lowest survival rate 40% as shown in the Table 4.6. In comparison with T0 (OTC-HCL), 20 mg/L was recorded low survival rate 60%. And Control + (no treated group) were recorded 15% survival rate.

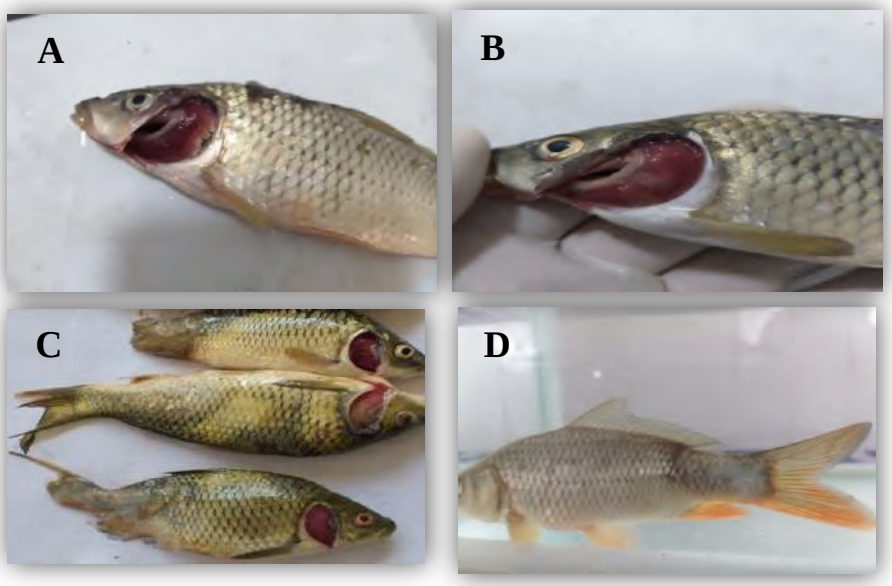
Table 1. Survival and Mortality Rate of *Cyprinuscarpio* treated with ChNP-OTC following challenge of *F. columnare*

Treatment	Total number	No. of dead fish	Survival rate%	Mortality rate%
Control(-)	20	0	100	0
Control(+)	20	17	15	85
T0	20	8	60	40
T1	20	12	40	60
T2	20	11	55	45
T3	20	6	70	30
T4	20	2	90	10
T5	20	9	55	45

3.2. Clinical signs of C. carpio before and after treatment:

In the experimental infection test and pretreatment, the moribund fish showed off feed, swam on the surface of the water with increased operculum movement without reflecting the external impact and staying on the side before death. The gross symptoms involved a mild discoloration of the skin. Hemorrhagic swelling mainly at the injection site, gills also congested with necrotic lesion patches, Mortality of fish started after 4 days post-injection *F. columnare.* These symptoms are shown in figures (1. A, B, C&D).

One week after the end of the treatment period, an improvement in health was observed, as well as swimming and breathing also was regularly, especially in T4, T3, T5.and T0 also Control$^{(-)}$. Post-treatment the feed was given to the fish in all groups at the rate of 2%. No feed consumption in C+, T1 and T2. While in T4, T3, T5, T0 all the feed was consumed, and the fish were active and swim normally.



Figures 1. (A&B): gills congested with necrotic lesion patches. (C): mild discolouration of the skin and hemorrhagic swelling (D): Hemorrhagic swelling at the injection site.

3.3. *Hematological parameters:*

3.3.1. Red blood cells count (RBC)

The results revealed significant increases (P<0.05) in RBCs count of *C. carpio* post-treatment in treated groups T4 (2.26 cell×10^6/mm^3) compared with control (+) group (1.40 cell×10^6/mm^3) and another treatment .Table (4.8.1). However no significant difference (P 0.05) with control (-). While, treated groups T0, T1, T3 and T5 (1.61, 1.56, 1.73 and 1.56 cell×10^6/mm^3 respectively) were revealed slight increases and no significant difference (P 0.05) with C+ and between them, Table **2**, and there were a significant decreases (P<0.05) in Control (+) compared with control (-).

3.3.2. Packed cell volume and Haemoglobin (PCV, Hb)

In the Table 2, there were significant increases (P<0.05) in concentration and packed cell volume and haemoglobin in treatments T3, T4 and T5.That were (20.43, 26.46 and 21.13 % respectively), and (7.31, 8.95, and 7.03 g/dl respectively) compared with Control (+) (15.95% and 5.94 g/dl) and recorded highest values in T4 from all other treatments which no and no significant difference (P > 0.05) with Control (-). In T0, T1, and T2 (19.40, 16.76, and 18.36% respectively) and (6.46, 5.59, and 6.07 g/dl respectively), that were no significant difference between them, but there is a significant increases (P<0.05) with Control$^{(-)}$), and there were a significant decreases (P<0.05) in Control$^{(+)}$ compared with Control$^{(-)}$.

3.3.3. White blood cells (WBC)

In Table 2, the results revealed no significant difference in WBCs count of *C. carpio* post treatment in group T0 (19.26×10^3cell/mm^3) compared with Control $^{(-)}$ and Control $^{(+)}$ ((17.94 and 19.13×10^3cell/mm^3 respectively). However, the recorded highest mean values and significant increases (P< 0.05) in, T1, T2, T3, T4 and T5 (22.10, 23.36, 22.03, 21.00 and 20.50 ×10^3cell/mm^3respectively) in comparison with Control (-), but no significant difference (P 0.05) between them. Highest mean values in T1.
These results mean WBC numbers showed a significant increase (P< 0.05) in treated groups.

Table 2. Hematological parameters of *Cyprinuscarpio* treated with ChNP-OTC following challenge of F. *columnare*

3.3.4. Biochemical parameters

Results of total protein, albumin, globulin, A/G ratio

Total protein level revealed a significantly increased($P \leq 0.05$),in treatments T2, T3, T4, and T5 (3.95 , 4.25 , 4.45 , and 3.85 g/dl respectively)compared with Control$^{(-)}$ and Control$^{(+)}$ (2.60 , 2.40 g/dl respectively).While, no important difference ($P > 0.05$) between them. In addition, the maximum levels were recorded in T4. Table 3. While the result of total protein in T0 and T1(2.40 and 2.91 g/dl respectively) revealed no important difference ($P > 0.05$) with Control$^{(-)}$ and Control$^{(+)}$.Also, Albumin level revealed a significantly increased ($P \leq 0.05$),in treatments T2, T3, T4, and T5 (1.75, 1.95, 1.76, and 1.57 g/dl respectively)compared to the Control$^{(-)}$ and Control$^{(+)}$,(1.45,and 1.19g/dl respectively).Whereas, the result of Albumin in T0 and T1(1.16 and 1.29 g/dl respectively) revealed no significant difference ($P > 0.05$) compared with Control$^{(-)}$ and Control$^{(+)}$.and between them. This recorded in Table (3).

As well, Globulin level in this trial resulted in a significantly increased ($P \leq 0.05$),in treatments T2, T3, T4, and T5 (2.20, 2.30, 2.68, and 2.21 g/dl respectively)compared to the Control$^{(-)}$ and Control$^{(+)}$,(1.15,and 1.20 g/dl respectively).While, T0, T1(1.24, and 1.63 g/dl respectively) revealed no significant difference ($P > 0.05$) compared with Control$^{(-)}$ and Control$^{(+)}$.and between them. The result of A/G ratio revealed a significantly decreased ($P \leq 0.05$) in all treatments in compared with Control$^{(-)}$ and no significant difference ($P > 0.05$) compared with Control$^{(+)}$.The best ratio recorded in T4 and T5 but not differ significantly from T3 , T2 and T1as shown in Table 3.There were a significant decreases($P<0.05$) in Control$^{(+)}$compared with Control$^{(-)}$.

4. Discussion

The presence of skin lesion and gill necrosis are similar to characteristic lesions reported by Kubilay *et al*. (2008). Columnaris disease is primarily an epithelial infection that causes necrotic gill or skin lesions (Thune, 1993; Noga, 2000). Off feed and swim at the surface with increased operculum movement are observed by Tripathi, (2003). In addition, Tien *et al*. (2012) showed the infected striped catfish swim frequently with convulsions at the surface of the water, in particular, apparent in the first 24 hr post-bacterial exposure. The gills in these fish turn into a deep red color with alternate white patches. In addition to that, these fish had de-pigmented patches on the body, with a yellowish

discoloration on the fins. Finally, they had more severe tail erosion and the gills were fully necrotic. Between 48-52hrthe mortalities happened after exposure to experimental bacterial immersion. In this study, the possible application of synthetic ChNPs for OTC administration in carp fish was evaluated. To date, there is a powerful need to develop new and alternative administration processes for this antibiotic in the aquaculture sector due to its wide use (Rigos and Smith, 2015). Exposure to ChNPs-OTC did not cause any important stress response in treated fish, that agreement with Chemello et al. (2015) when utilizing them the Oxytetracycline delivery in adult female Zebrafish by iron oxide nanoparticles.

The results of this study revealed a significant increase in survival rate in T4 and T3 and mortality rates decreased from 85% in the infected non-treated group to 10 and 30% in these immersion-treated groups, respectively. There are no similar studies. While, Rach *et al*.,(2008) In the channel catfish trial, survival at (10 days) post-treatment was remarkably ($P > 0.05$) greater for all Oxytetracycline-hydrochloric treatment groups comparative to controls, and the Oxytetracycline-hydrochloric treatments effectively decreased mortality in walleyes (10 mg/L only) and channel catfish infected with F. columnare.

Another study, Julinta *et al*.,(2017) evaluated the effectiveness of ox tetracycline (OTC) oral and bath therapies on Nile tilapia *Oreochromisniloticus* against *A. hydrophila* infection, where they are found The oral and bath therapies in fries with OTC recorded low mortalities (17 and 21%) than the respective control. In this study we comparison with some studies of oxytetracycline effect of the fishes, also effects of chitosan nanoparticles studies compared to ChNP-OTC that due to no similar comparison studies in vivo. Hematological parameters have been recognized as valuable tools for assessing the health status of fish. These parameters are affected by several factors, such as species of fish, age, period of sexual maturity and health status (Blaxhall, 1972; Hrubec *et al*., 2001).

Changes in physicochemical parameters may be reflected in blood parameters of the fishes (Abdul Naveen *et al.,* 2011). The results of this study revealed a significant decrease in RBCs count, Hb content and PCV% in non-treated Control$^{(+)}$ compared with control$^{(-)}$ group, but there is slight increase in WBC value in Control$^{(+)}$ than control$^{(-)}$. All of that agreement with (Tripathi *et al*., 2005), when they registered considerable changes in blood parameters were noticed in the infected koi carp fish. For the hematologic parameters, a remarkable reduction was observed in hemoglobin concentration, Packed Cell Volume (PCV), and red blood cell count. From our observation on all treatments there is increase the RBC count value in all treated groups compared with no treated group (Control $^{(+)}$). In addition, the higher value in T4 which has low dosage of ChNP-OTC 5mg/L where, recorded the less stress during treatment period on carp fish. That agreement with (Chemello *et al*., 2016) where they was recorded the exposure of Oxytetracycline Delivery in Adult Female Zebra fish by Iron Oxide Nanoparticles fish to the complex resulted in a 10 times higher OTC accumulation with respect to using water exposure. In addition, in fish exposed to 4 mg/L OTC (using water), the liver antibiotic concentration was very low during the completely experimental time.

Also agreement with (Nikapitiya *et al.*,2018) where was recorded Chitosan nanoparticles: a positive immune response modulator as display in zebra fish larvae against Aeromonas Hydrophila infection and CNPs exposure at 5 μg/mL could enhance the immune responses and develop the disease resistance against A. hydrophila, which could be attributed to its strong immune modulatory properties. The result of PCV and Hb value in our study showed decrease significantly ($P < 0.05$) in higher concentration treatment T0, T1, and T2. This decrease is compatible with previous studies showed that OTC can be responsible for the induction of toxicity in fish liver by altering the activity of enzymes involved in stress response(Bruno, D. W. 1989; Pari and Gnanasoundari, 2006; Nakano *et al*.,2018).Also, PCV and Hb value in T4 recorded increase significantly ($P < 0.05$) compared with all treatments.

In this study, the WBC count showed increase significantly in T0, T1, T2, T3 and T5 compared with Control $^{(-)}$.While in T4, the deference is insignificantly. Increase in number of WBC in diseased fish could be serving as a protective barrier towards any infection (Talpur and Ikhwanuddin, 2013). Moreover, WBCs are one of the most affecting factors in immunity of fish and WBC counts

has been used as marker of health of aquatic animals (Duncan and Klesius, 1996). That depend on range of immune response against bacteria. The antibiotic generally inhibits growth of the pathogen allowing the immune system to eliminate the invaded microorganisms and chitosan nanoparticles and its loaded antibiotics kill and inhibits the growth of bacteria due to the antibacterial activity increased with increasing the antibiotic content, that agreement with (Ibrahim *et al*., 2015)

In the study by Sebastião et al.,(2011) they have recorded the blood parameter results from naturally infected tilapia displayed that there were changes in the erythrocytic series and in organic defense blood cells, in the fish infected with the bacterium, with a decrease in erythrocytic variables and important raise in the numbers of neutrophils and circulating lymphocytes. The total serum protein appeared the most significant indicator of the nutritional state of the health condition of fish (Patriche, 2011). Other researchers notified that the total protein concentrations, albumin, and globulin in the plasma is an indicator of liver function and subsequently the reduction of serum protein may be referred to renal excretion or impaired protein synthesis, or because of the liver hypofunction or disorder (Bernet et al., 2001).

In this study, Total proteins, Albumin and Globulin levels increased significantly in treatments (T2, T3, T4, and T5), that indicates an improvement of innate immunity for fish. This result is in line with Ranjan *et al*. (2014) in Asian seabass (*Latescalcarifer*). Similar findings recorded in olive flounder Cha *et al*.(2008), the rising level of total serum protein may be caused by the activity of bactericidal, activity of serum lysozyme, globulin content and perhaps a few other peptides (Misra *et al*., 2006).

5. Conclusions

The present study represents an important first step for the study of the effect of chitosan nanoparticles loaded with oxytetracycline hydrochloride on the health status of common carp with Columnaris disease. As a result, this new drug delivery method appears to be much better in relation to the conventional method of antibiotic exposure, as it reduces the dose of antibiotics and increases the survival rates against bacterial infection in fish, and reducing the antibiotic-resistant fish, and reduces the potential environmental impacts. However, the action of chitosan nanoparticles-loaded oxytetracycline is unclear and more studies are needed to understand its mechanism of action and side effects on fish industry.

Calculation of Concentration of Radon Gas in Specimen of Rivers Water samples in Diwaniya-Iraq'By Using CR-39 Track Detector

Calculation of Concentration of Radon Gas in Specimen of Rivers Water samples in Diwaniya-Iraq'By Using CR-39Track Detector

Abbas A. Sweaf[1]

[1]Physics department, College Education , AL- Qadisiya University / Iraq

E-mail: abbas .abd@qu.edu.iq

Abstract. The concentration of radon gas in a specimen of water of specific areas in 'Al - Diwaniya"province was calculated through employing alpha-emitters registrations, which is in'(CR-39)"nuclear track detector. The study focuses in determining the concentration of the gas in tap water specimen provided by the water grid of houses in 'Al- Diwaniya province. The findings indicate that the radon maximum level in water' 'specimen was in (Alshanaafia 5) area assigned to be (0.56 ± 0.30 Bq/L), and the minimum level' is in'(Afak 5) area around (0.165 ± 0.031Bq/L), in addition, to a rate value of (0.336 ± 0.075 Bq/L). The results also indicate that the radon gas in tap water is less than the acceptable boundary from (ICRP) organization which is (0.5994 Bq/ L),but the concentrations of radon exhalation rate (RER) is about '(0.245– 0.072 μSv/y) and the rate value is '(0.1462 ±1.23 μSv/y).

Keywords : radon concentration ,'ground water, annual effective dose,CR-39,; Al- Diwaniya province'

1. Introduction

A radioactive gas 'Rad0n (222Rn)' with a (t1/2t= 382d)'is made by the degeneration of natural 'radionuclide'(226Ra) which is basically a degeneration result of uranium (238U) chains. A radon isotope, Thoron gas (220Rn) "is a degeneration result of the thorium (232Th) chains. Thoron half- life is (56 s) which is less than the radon [1].The concentrations of radon gas in ground'-'water depends on the geological circumstances of the' area in addition to the human activities' pollution such as 'phosphate fertilizers, mining, and combustion of coal 'or other fuels .The rocks that happened naturally' by dissolving the granite rocks in natural uranium was mixed with the ground-water through leaching and precipitation (illumination process) [2]. In current examinations, the passive technique called the solid situation nuclear track detectors SSNTDs is used. The Nuclear track detection technique which depends on radon size and'CR-39 detector used in' the present work due to its' clarity and continuing integrated read out; high sensitivity to alpha-particle radiation ruggedness, which is available and easy to handle [3];.The radon that exists in tap water represents a hazard for developing cancer of organs such as stomach cancer. Nevertheless, this hazard is nothing beside the hazard of developing lung cancer from radon released by water to air especially when water comes out a tap and the melted gases are free [4]. Actually, the study covers the area that is situated in Al-Diwaniya province in further parts of Euphrates, see figure 1. The goal of the study is to identify the

concentration of radon gas in a specimen of tap water in selected areas in Al-;Diwaniya province by employing alpha-emitters registrations that are released from radon gas of in CR-39 nuclear track detector using;sealed-cup technique [5].

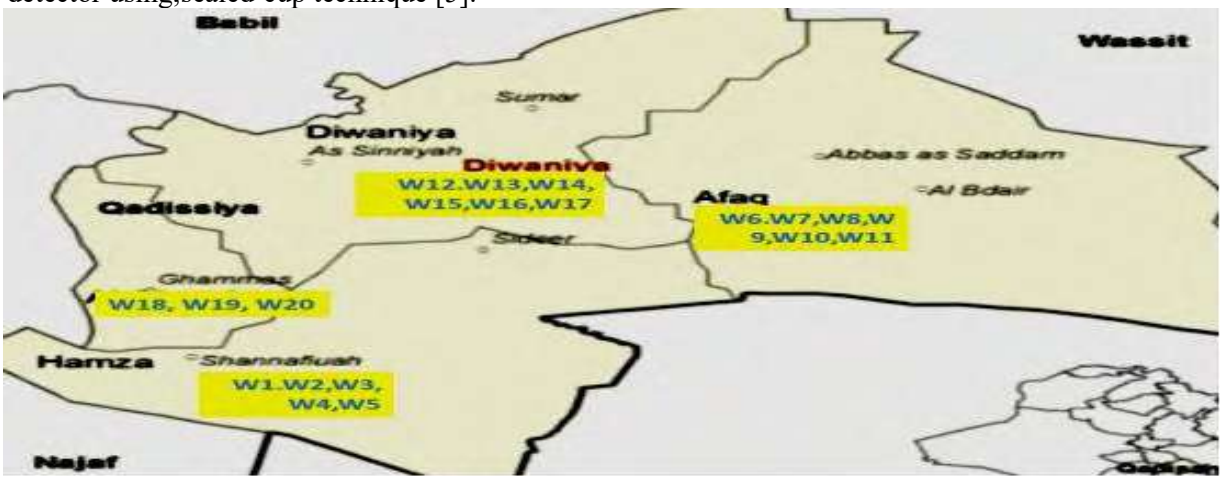

Figure 1. The dots are the locations where specimen taken from in Al-Diwaniya province with the numbers of stations.

2. Experimental Method

In this work, 20 samples of water were collected from different locations in some areas of Al-Diwaniya governorate as shown in figure 1. Each sample with 0.25 liter was placed at the bottom of a cylindrical sealed can of 10 cm height and 6 cm diameter. Solid State Nuclear Track Detector (SSNTD) with sheet thickness of 500μm was used in this study, which is usually known as CR-39 plastic detector [14]. Square pieces of detector of the sizes (1 cm × 1 cm) were fixed on the top of the inner surface of the can, in such a way, that the sensitive surface is always facing the water's sample [6]. The detectors were exposed to a period of 60 days. During exposing, the sensitive side of the detector is always facing the sample, and is exposed freely to the emergent radon from the water sample, so it could record alpha particles resulting from the decay of radon in the remaining volume of the can as seen in figure 2. After completing the exposure, the detectors were collected and chemically etched using 6.25 N NaOH at (70 C°) for (6 h). After that, these SSNTDs were washed, dried and scanned using an optical microscope with magnification of 400X (40x objective and 10x eyepiece) to count the number of the tracks per cm^2 in each detector. The determinations of the concentrations of alpha particles from radon gas in the samples were performed using CR-39 from the Intercast Europe Srl Company [7]. The radon gas concentration in the ground water samples was obtained by a comparison between track densities registered on the detectors of the ;sample and that of the standard water samples; using the following relation [8]

$$Tracks\ density\ (\rho) = \frac{Rate\ number\ of\ total\ pits\ (track)}{area\ of\ field\ view} \quad (1)$$

; The concentration of the radon gas is calculated using the following relationship [9].;

$$C_x = \rho_x \left(\frac{C_s}{\rho_s}\right) \quad (2)$$

where
C_X: the concentration of alpha molecules in an unidentified specimen
C_S: the concentration of alpha molecules in the standard specimen
ρ_X: Density of track of an unidentified specimen; (track/mm^2)

ρ_S: Density of track of the standard specimen; (track/mm^2)
The effective dose per year for a consumer based on the radon intake of ground water is assessed through the relationship [10].;

$$AED_w = C_w CR_w D_{cw} \quad (3)$$

;where AEDw is the annual effective dose (Sv/y) due to the absorption of radionuclide from the consumed water.;
Cw is the concentration of radon in the consumed ground water (Bq/L)
C_{Rw} is the annual intake of drinking water = 1095 L/y;
Dcw is the ingested dose conversion factor for = 4 Sv/Bq;[11].

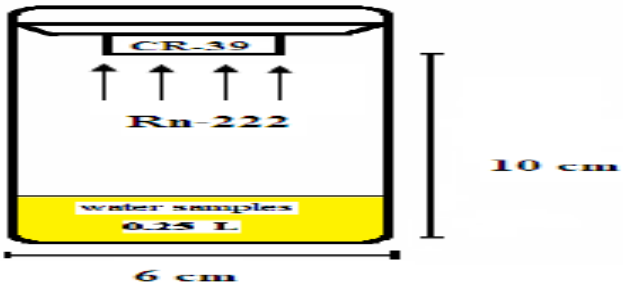

Figure 2. A graphic figure of the technique of;sealed-cup in water specimen

3. Results and Discussion;

In this survey, a total of 20; specimens of drinking water are collected from various regions in;Al-Diwaniya ;province through sealed-cup technique. Table 1 and Figure (4) shows the concentration of radon gas in the specimens of drinking water; from various areas in the;Al-Diwaniya province. It may be noted that the maximum level of the concentration of radon gas in the specimen of potable water is found in (Alshanaafia5) area which equal to (0.56 ± 0.30 Bq/L), while, the minimum level is found in (Afak 5) area which equal to (0.165 ± 0.031 Bq/L) and a rate value of (0.336 ± 0.075 Bq/L). Al shanaafia5 area has the maximum value of the annual effective dose in the specimen of potable water equal to (0.2452μSv/y), and the minimum value of the annual;effective dose (AED) is in;(Afak 5) area equal to (0.0722 μSv /y), and the rate value of (μSv /y) (0.1462 ± 1.23 μSv/y).;The annual effective dose (AED) of all the specimens are below the standard world parameters, which is equivalent to (1μSv/y).;Hence, the potable water in Al-Diwaniya province is safe as far as the concentration of the radon is concerned.; The recent paper measures the concentrations of the radon gas in 20 ground water specimens taken from different compartments (five specimen in each site) in Al-Diwaniya province by employing the sealed-cup technique. Based on the results, the concentration of the radon gas in the specimens of tap water in Al-Diwaniya Province (Iraq) is less than the permitted parameter from;(lCRP) agency that is equal to (0.59 Bq/L) [12]... ; ;

4. Calibration Curve for standard samples

To calibrate the curve plot between standard of different concentration of the radon gas solutions of known concentrations from;(**0 – 0.55** Bq /l) that have been arranged to calibrate the paper and track the density using neutron induced radiography that is depended on the norm of solid state nuclear detectors SSNTDs;CR-39..The concentrations of radon gas are calculated by comparing track dense register on the detectors of the specimen and the standardized specimen from the Regression equation : ;**y = 130.55 X +1.446 , R^2 = 0.9968**. A linear calibration as seen in Figure (3) is detected, tracked by measuring the slope. The findings are investigated in (mg Bq/L)..

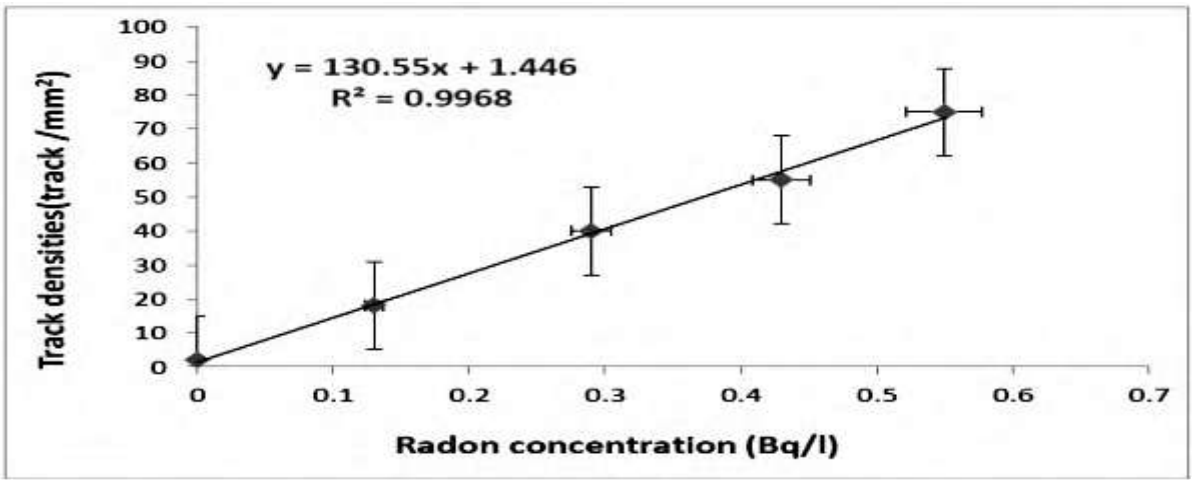

Figure 3. Relationship of concentration of gas of radon and density track in standardized specimen of water.

Abstract. In this work, based on Mach- Zehender Interferometry (**MZI)** technique, a single-mode optical fiber had been designed as a water pollution sensor. The submitted sensor had been designed to detect pollutants in water. The sodium chloride salt and sugar were used as simulation examples of pollutants with different concentrations (0-0.45) mol /liter. The performance of the submitted sensor had been studied for different sensor arm diameters which were (63.5, 51.58, 39.68 and 20 μm). The variation of the refractive index of salty and sugary solutions surrounding the sensor leads to a change in the optical properties of the transmitted signal. In this work, a wavelength shifting had been obtained due to this variation. The influence of sensor diameter on the sensitivity of the system had been studied. From the results, we found that the higher sensitivity was for the sensors with a diameter of 20 μm, and they were 1130 pm/mol.l^{-1} and 1205 pm/mol.l^{-1} for salty and sugary solution respectively.

Keywords: optical fiber sensors, RI sensor, evanescent field, MZI, chemical etching, water pollution

1. Introduction

Related to the toxic effects the pollutants may have on humans, accurate measures of chemical species in water have increasingly gained functional significance. In this context, it is important to build up simple, responsive, low-cost, and portable water pollution sensors capable of direct measurements. Optical fiber technology provides many benefits for chemical sensing over traditional methods [1]. Compared to traditional devices, fiber optic sensor systems provide various advantages, including immunity to electromagnetic interference, lightweight and portable size, sensitivity, multiplex ability, remote sensing, and the most significant benefit is the ability to be built into the textile structure. An effective medium to sense chemical species is created by optical fibers. Light properties including intensity, phase, or polarization in the optical fiber may be modulated by the presence of chemical species. At the fiber output, these modulations can be observed and correlated with the concentration of the chemical species presented at the point. [2]

Any optical fiber consists of two dielectrics that are concentrically arranged: the center (core) and the cladding. A higher refractive index than the cladding is distinguished by the core [3]. Using HF as the etching agent is one of the simple methods used to make tapers. If the fiber is etched, as the fiber diameter is limited, the conditions controlling the transmission of light within the fiber change. It should also be remembered that the etching procedure is limited to a particular fiber length to achieve desired etched length and desired contact area [4]. In that configuration, it defines light propagation dependent on a total internal reflection. In the form of modes in the center and a small portion of energy penetrating the cladding known as the evanescent field, light is propagated. As a result, an exponentially greater cross-section of the cladding fills the area of the simple mode until it reaches the point where it is directed across its entire cross-section. A progressively greater cross-section of the cladding occupies the area of the simple mode until it reaches the point where it is directed in its cross-section. The change in boundary conditions is also closely associated with the change in the dimensions of the optical fiber. The light at the core/cladding interface is not propagated, but the air/cladding interface is propagated. The approximations used in the typical optical fiber mode solutions where the difference in refractive indices is small (less than 1%) are not valid. In this case, the light beam continues to be exposed and affected by the fiber surrounding air for tapered optical fibers where the light beam propagates in a whole system (as a core) and the environment becomes a cladding, as seen in Figure 1 [3]. As the optical fiber becomes more sensitive to external changes in the refractive index of the material surrounding the fiber, this method enables one to use additional material in an etched environment, especially in the tapered waist region. These links to different materials have been commonly used for the construction of sensors, filters, and amplifiers [5,6].

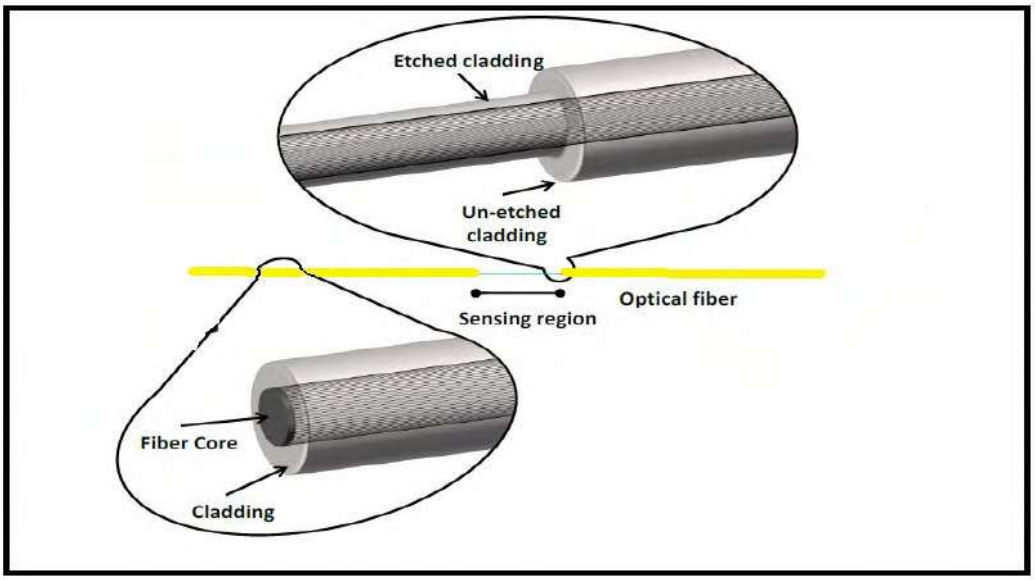

Figure 1. The schemes of the etched and non-etched region of optical fiber [7]

In biological fields, medicine and environment, optical fiber refractive index (RI) sensors are used. Many fiber optic RI sensors, such as Mach-Zehnder (MZIs), Fiber Grating, Fabry-Pérot (FPIs), Sagnac, and multi-mode interferometers have been published in the literature so far [8].
In particular, (MZIs) interferometers obtain from high sensitivity, a high degree of integration, accessibility and design compactness. Several optical fiber refractometers have recently been documented to allow the refractive index and many other parameters to be calculated simultaneously. These optical fiber instruments serve as evanescent wave sensors based on multimode interference systems, enhancing the dependency on high-order mode propagation constants on the external medium's refractive index to monitor changes in the environment's optical properties [9].

Many research groups submitted many research papers to solve many problems related to this very important topic.

James et al 2017 [10] stated that by depositing a nanoscale coating of titanium dioxide containing porphyrin as a functional material onto a tapered optical fiber, a highly sensitive ammonia sensor was developed. As a result of the interaction between porphyrin and ammonia, the difference in the refractive index of the coating material caused a change in the middle wavelength of the large-mode resonance, allowing the identification of ammonia concentrations in water as low as (0.1) ppm, with a reaction time of less than 30 sec. **Also, Devi et al 2018** [11] detected arsenic components in a drinking water, and MZI based on optical fiber was developed. The developed sensor is distinguished by its cost-effective, small, and laboratory-on-chip manufacturing capability. **In 2019 Ahsani et al** [12] a uniformly tapering SMF standard for MZI-based RI measurement was established. There are various applications in chemical and biochemical sensing fields for the suggested cheap and highly sensitive optical fiber RI sensors. **Finally in 2020 Ferria** [13] tested the distilled water solution mixed with methylene blue (MB), and an unclad optical fiber sensor was manufactured. At the core – liquid cladding interface, the manufactured sensor is based on evanescent wave absorption by the surrounding medium. Ferria concludes that the results showed that the designed sensor provides an effective response to the (6–50) mg / L concentration range.

In this work, an MZI sensor based on SMF had been designed for environmental applications. Sugary and salty liquids with different concentrations were employed as a simulation of water pollution. Moreover, the influence of the sensing arm diameter on sensor performance has been studied.

2. Experimental

The experiment was carried out using a section of the commercially available SMF of cladding and core diameter of (125 and 9) μm respectively.

About 3 cm length of the middle region of SMF was stripped and cleaned very well. After that, this section was immersed into Hydrofluoric acid (HF) to be chemically etched, that is to say, reducing its diameter to the desired value. The concentration of HF acid before dilution was 48%, and this strong acid has been diluted with distilled water to a ratio of (1 mm^3 HF: 1 mm^3 distilled water). The etching process took place at room temperature and the required cladding diameters have been achieved at etching times of (60, 90, 20 and 150) min. Then, the etched area had been cleaned very well using distilled water to remove any acid residuals.

Figure 2 below shows the MZI optical fiber sensor. A signal from the light source (single-mode fiber pigtailed Laser diode source -Thorlabs of center wavelength 1550 nm, and power 1.5 mW) was split by 2x1optical coupler (50/50) into two signals. The first signal goes to the reference arm while the second goes to the sensor arm. Then, both arms were collected using another 2x1 optical coupler. The output port was connected to Optical Spectrum Analyzer (THORLABS 203) with a wavelength range of 1000 to 2600 nm, and a resolution of 0.1 nm.

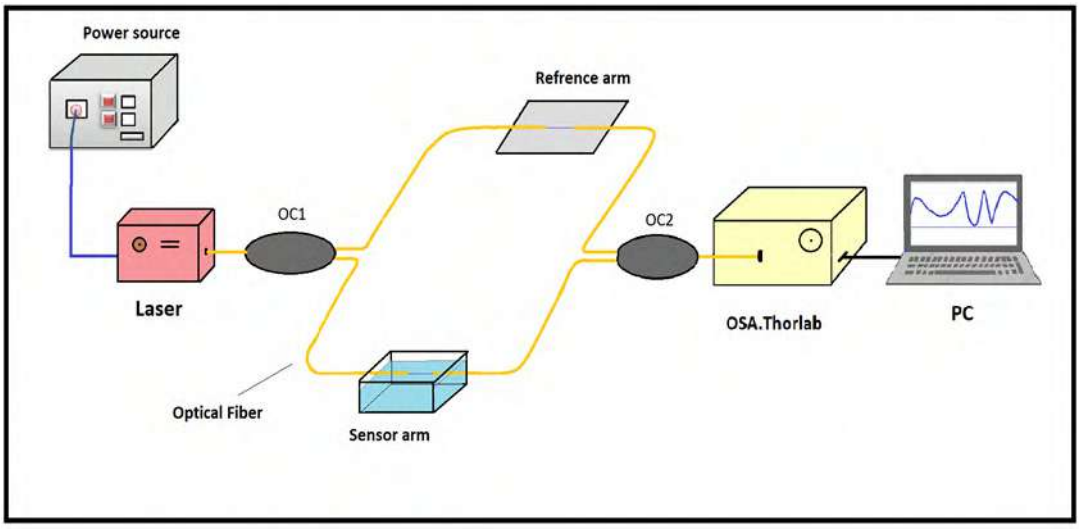

Figure 2. Schematic diagram of MZI- RI sensor

The tested solutions of sodium salt and sugar were prepared at different concentrations using the following equation:

$$C = \frac{m}{V} \times \frac{1}{MW} \quad (1)$$

where C is the molar concentration in mol/L (Molar or M). This is also referred to as molarity, m is the mass (i.e., weight) of solute in grams (g) that must be dissolved in a volume V of the solution to make the desired molar concentration (C) and MW is the molecular weight in g/mol.

The refractive index of the salty and sugary solutions was measured with a (BOECO Digital ABBE Refractometer)

The sensor arm was immersed in these salty and sugary liquids with different concentrations and the transmission spectrum was collected and analyzed using OSA.

3. Results and discussion

It is observed experimentally through the refractometer that the refractive index increases with increasing the concentration of sodium salt or sugar in water, as shown in Figure 3.

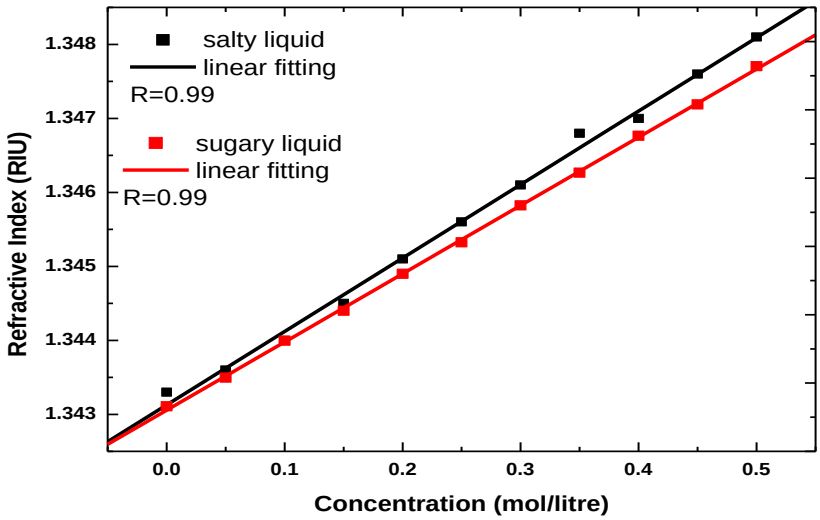

Figure 3. Refractive index variation with concentration

The different diameters of optical fibers due to different etching times were obtained and illustrated in Table 1.

Table 1. The variation of the etched fiber diameter with immersion time

Fiber no.	Etching time (minute)	Etched fiber diameter (μm)
1	60	63.5
2	90	51.58
3	120	39.68
4	150	20

The diameter of the fiber in the area exposed to HF decreases during the etching process. According to the following reaction formulas, HF reacts to silica:

$SiO2+4HF \rightarrow SiF4+2H2O$

$SiO2 +6HF \rightarrow H2SiF6 + 2H2O$

The first formula dominates the reaction concerning the present work, while the second formula dominates acid circumstances with a high concentration. Instead of tapering, this method adjusts the cladding properties while keeping the core intact [14].

Since HF has known for its ability to dissolve silica, it became evident from experience that the length of etching time required was about 150 minutes and through the etching results in Table.1 of the fibers. The remaining fiber thickness was apparent from the fibers of (39.68) μm and (20) μm fiber diameter with etching times of (120) and (150) min, respectively. Remember that the core is (9) μm in diameter. Due to figure 4, the effect of changing the refractive index of the surrounding environment of the sensor arm on the optical properties of the transmission spectra was studied for the standard fiber diameter (125 μm). The sensor arm was immersed in distilled water, and from figure 4 one can notify a noticeable wavelength shifting towards the longer wavelength due to applied distilled water to sensing arm.

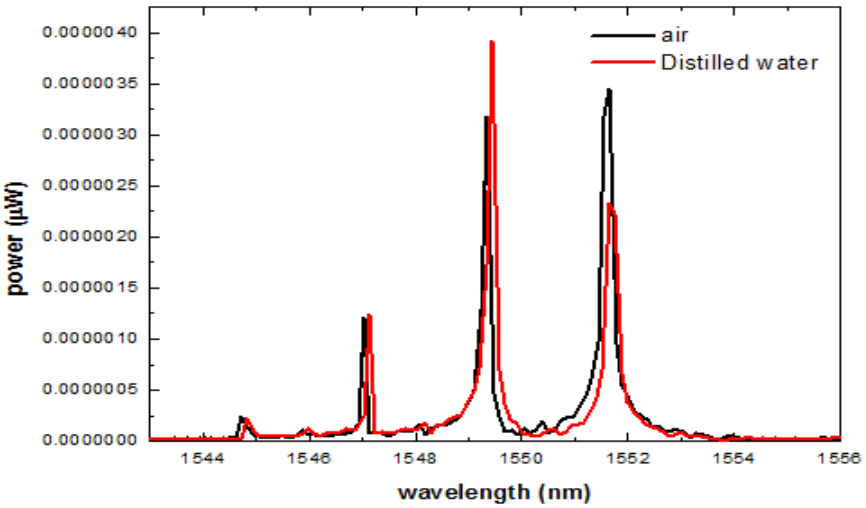

Figure 4. The transmission spectrum of air and Distilled Water

To test the system as a refractive index sensor, the sensor arm was immersed with different solutions; salt NaCl and Sugar $C_{12}H_{22}O_{11}$ with different concentrations ranging from (0 - 0.45) for both liquids. Figure 5 shows the transmission spectra of salty and sugary liquids at different concentrations.

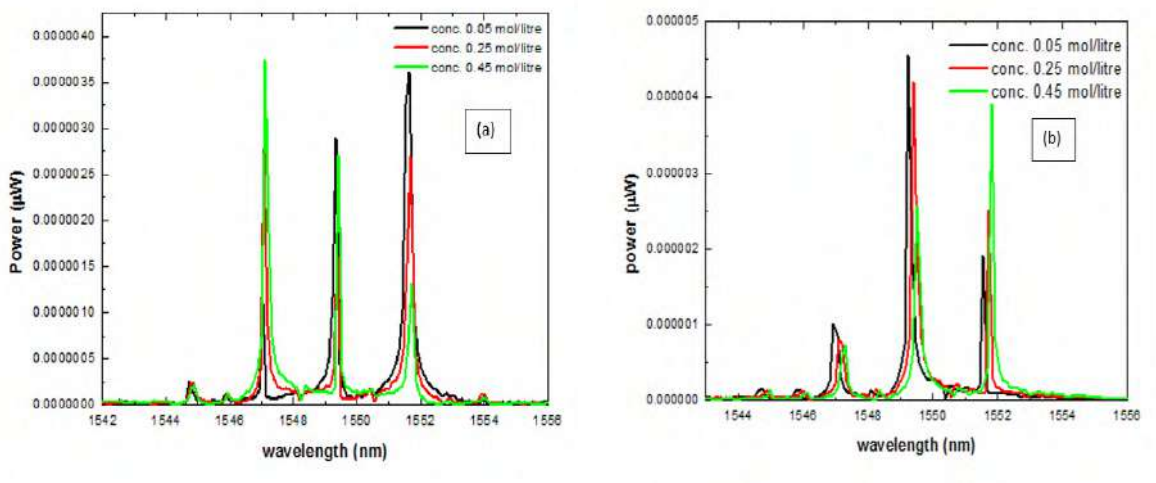

Figure 5. The transmission spectrum of (a) salty liquid, and (b) sugary liquid with selective concentrations

Figure 6 shows the linear relationship between changing in liquid concentration and shifting in the peak wavelength. The figure illustrates that the sensor shows a good sensitivity which is calculated from the linear fitting line and is equal to (202) and (220) mol/liter for salty and sugary liquids respectively.

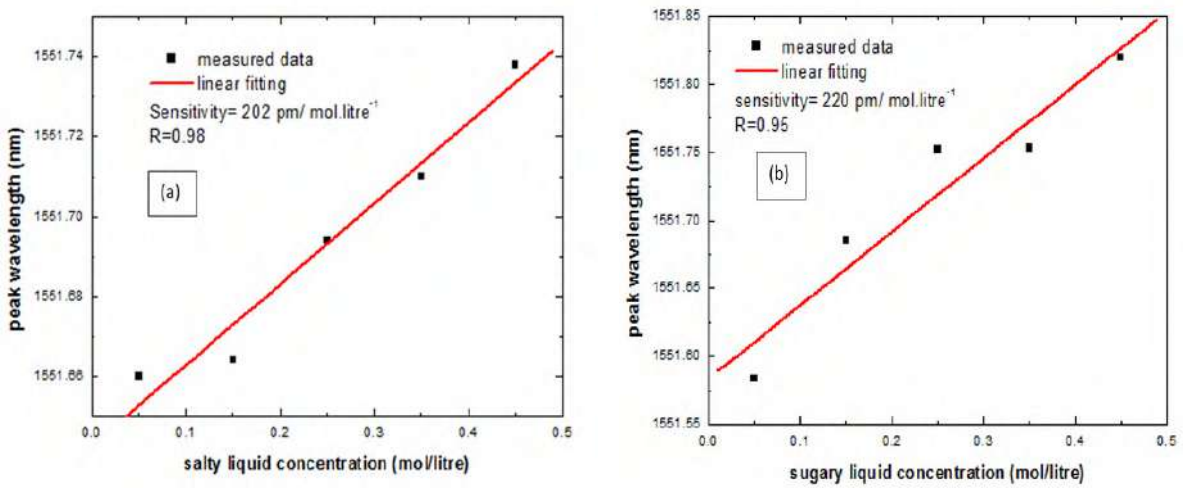

Figure 6. The relationship of peak wavelength shifting with liquid concentration for a selective peak, (a) salty liquid, (b) sugary liquid

The effect of sensor arm diameter on sensing performance had been studied. Different fiber with average diameters (63.5, 51.58, 39.68, and 20) µm were utilized and immersed in the sensing region with salty and sugary liquids with different concentrations.
Figure (7) shows the transmission spectra of salty liquid with different concentration for fiber average diameters (a) 63. 5 µm, (b) 51.58 µm, (c) 58.68 µm, and (c) 20 µm respectively.

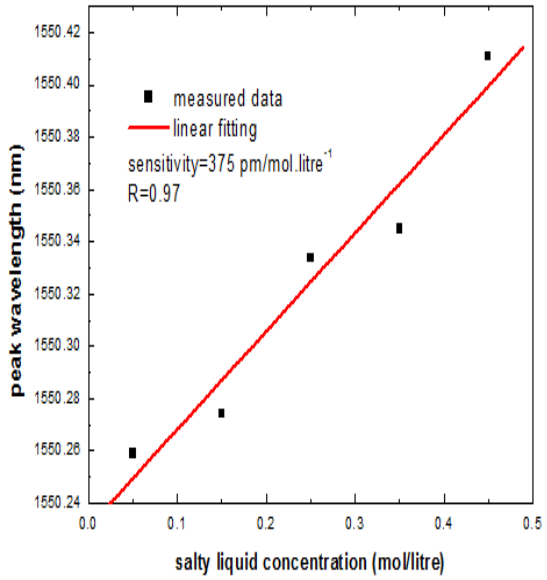
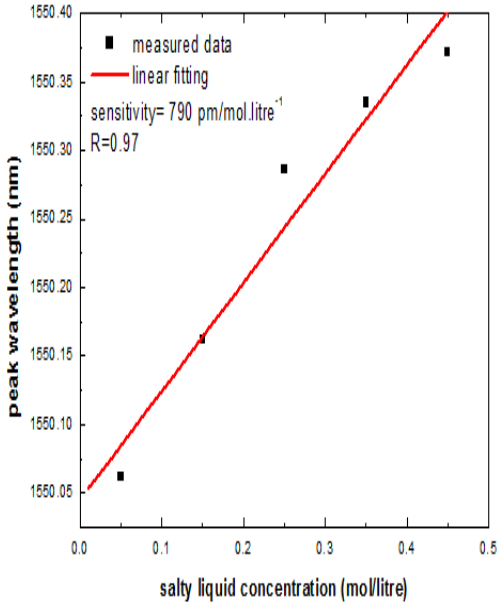
(d)

Figure 7. The transmission spectrum of salty liquid with selective concentrations with sensor diameter (a) 63.5µm, (b) 51.58µm, (c) 39.68µm, (d)20µm

Figures (8) on the other hand shows the linear relationship between the shifted in peak wavelength and liquid concentration for salty liquid with different concentration for fiber average diameters (a) 63. 5µm, (b) 51.58 µm, (c) 58.68 µm, and (c) 20 µm respectively.





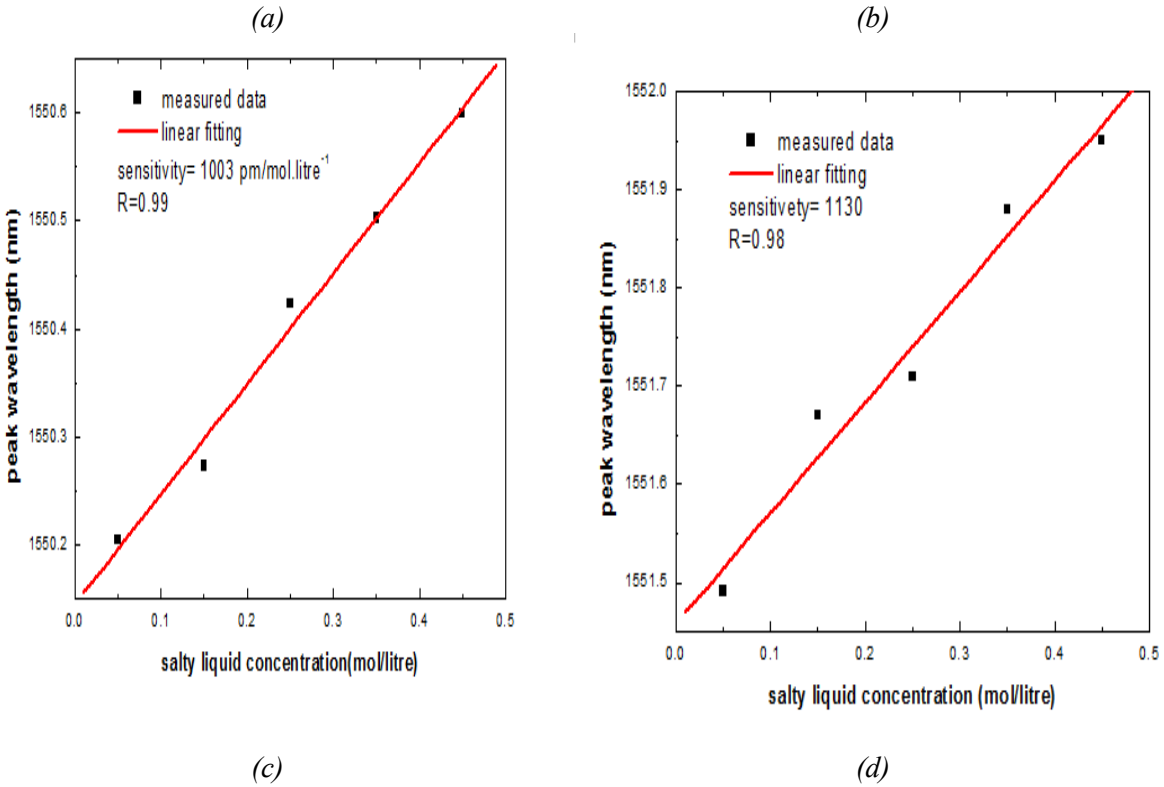


Figure 8. The relationship of peak wavelength shifting with salty liquid concentration for a selective peak, with sensor diameter (a) 63.5µm, (b) 51.58µm, (c) 39.68µm, (d)20µm

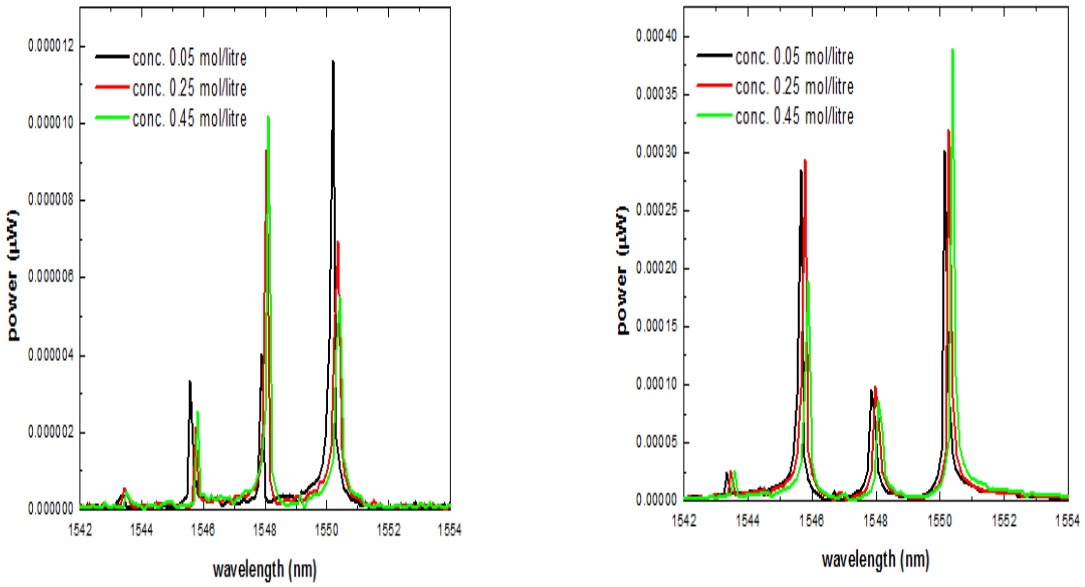
Figure (9) shows the transmission spectra of sugary liquid with different concentration for fiber average diameter (a) 63. 5 µm, (b) 51.58 µm, (c) 58.68 µm, and (c) 20 µm respectively.



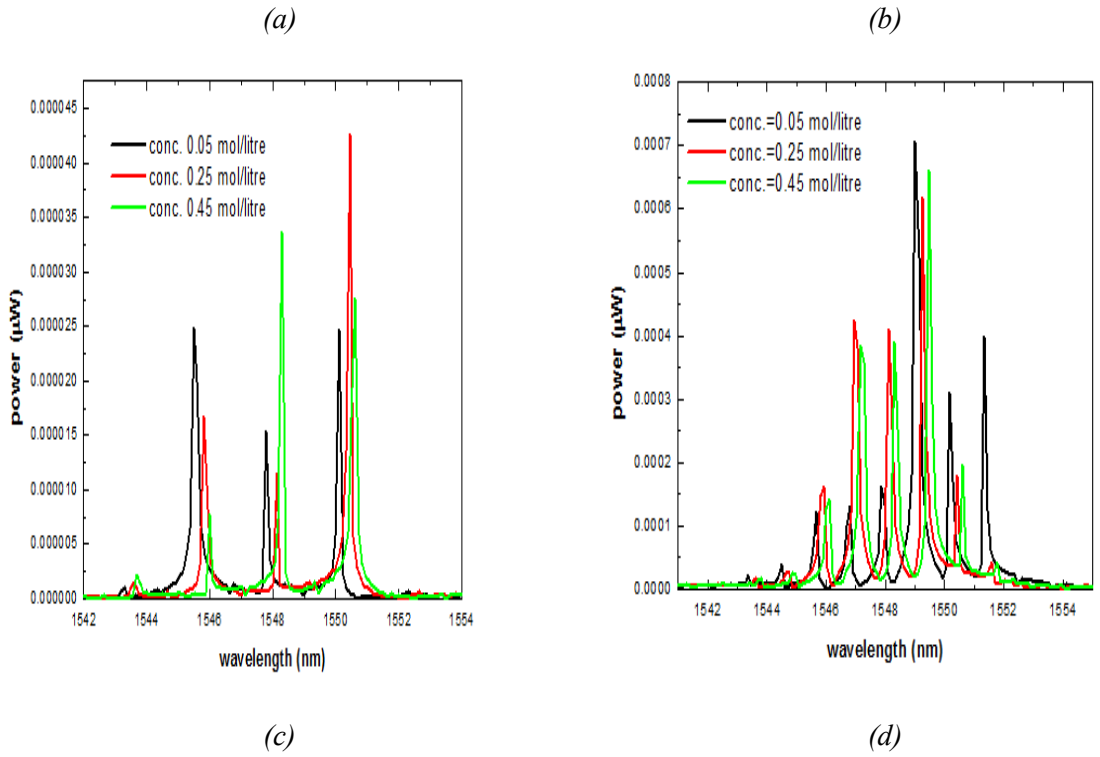


Figure 9. The transmission spectra of sugary liquid with selective concentrations with sensor diameter (a) 63.5µm, (b) 51.58µm, (c) 39.68µm, (d) 20µm

Figures (10) shows the linear relationship between the shift in peak wavelength and liquid concentration for sugary liquid with different concentration for fiber average diameter (a) 63.5 µm, (b) 51.58 µm, (c) 58.68 µm, and (c) 20 µm respectively.

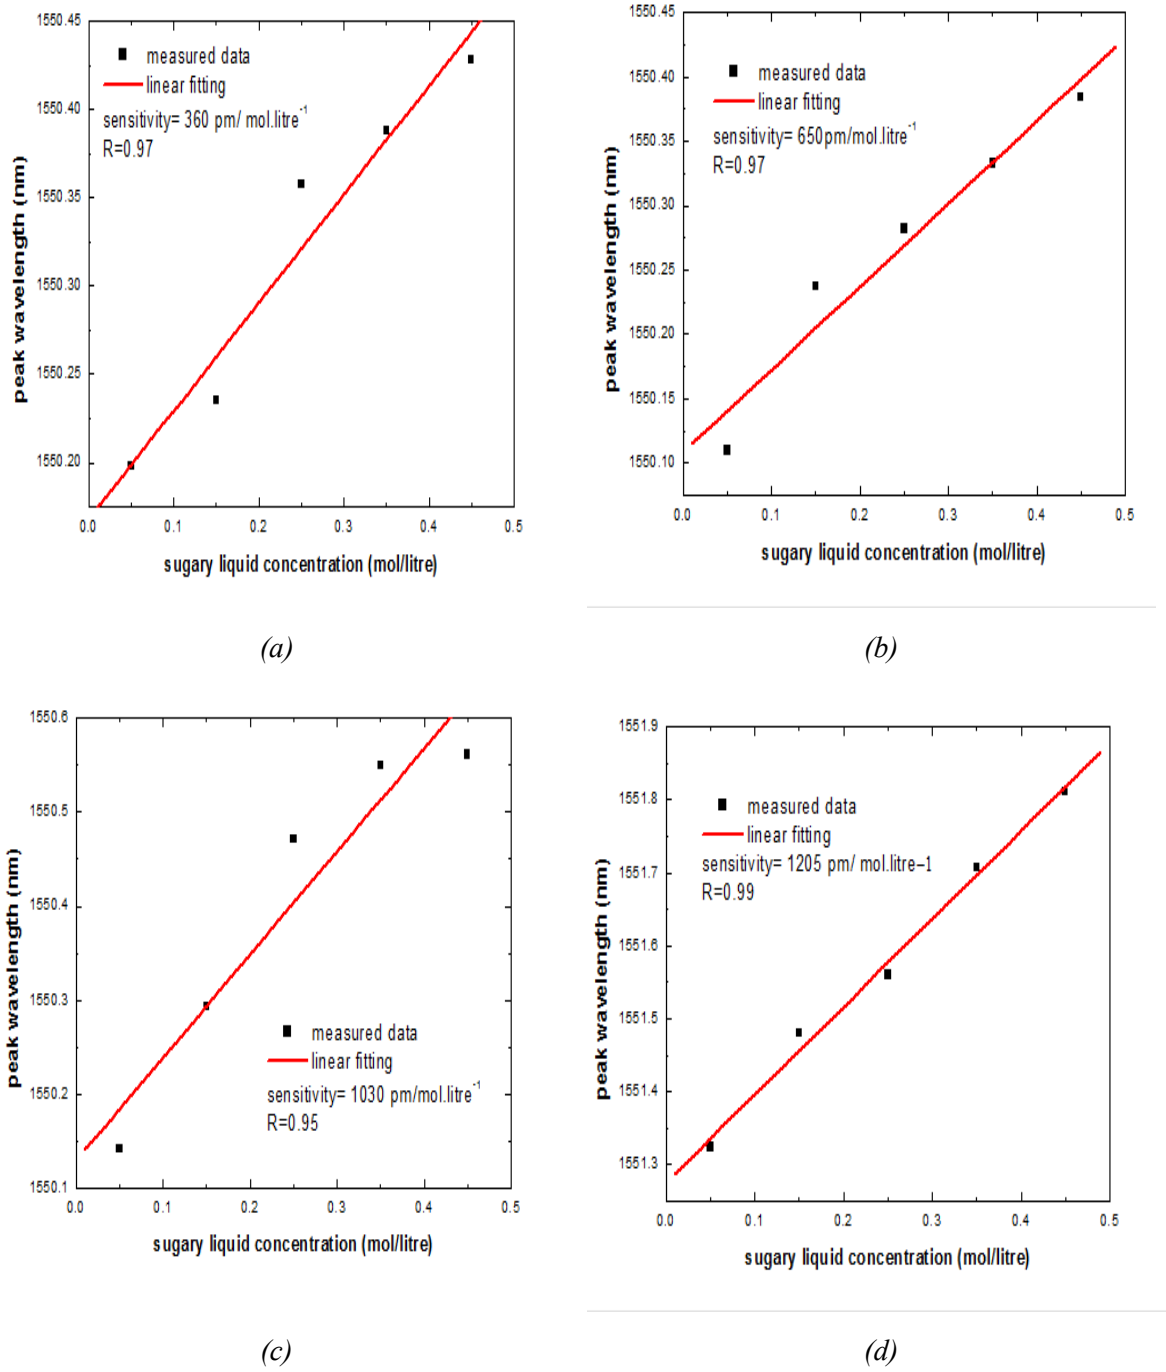

Figure 10. The relationship of peak wavelength shifting with sugary liquid concentration for a selective peak, with sensor diameter (a) 63.5µm, (b) 51.58µm, (c) 39.68µm, (d)20µm

Table (2) below shows the sensitivity of the submitted sensor for each case, from this table we can conclude that the sensor performance is enhanced as the optical fiber sensor diameter is decreased. This can be explained because the more leakage of the evanescent field from fiber cladding the more interaction with the surrounding media (liquids in this work). Also, the sensitivity values are close for

both salty and sugary liquids which declare that the type of liquid is not an important factor as its concentration on the sensing performance.

Table 2. Variation of the Sensitivity with optical fiber thickness

Fiber Dimeter (μm)	Salty liquid Sensitivity (pm/mol.litre^{-1})	Sugary liquid Sensitivity (pm/mol.litre^{-1})
125	202	220
NO.1 (63.5)	375	360
NO.2(51.58)	790	650
NO.3(39.68)	1003	1030
NO.4 (20)	1130	1205

From figures 9, 10, and Table 2 it could be noticed that the sensitivity of the submitted sensor had been enhanced by reducing the fiber diameter. The etching process leads to reduce the fiber diameter and thus strengthens the evanescent field. So, more light will be escape out of the cladding region and interact with the surrounding environments which are the salty and sugary liquids.
In standard optical fibers whose diameter is much greater than the light wavelength, the evanescent field strength at the outer surface of the cladding reduces to near zero. The light dispersed in these fibers is thus not influenced by the external environment, which decreases the interaction between the light and the sample and therefore reduces the sensitivity response of the optical fiber sensor. Carrying out the etching process and reducing the cladding thickness would allow the fibers to present large portions of ephemeral waves and surface fields of high intensity, rendering them extremely sensitive to the shift of the index to the surrounding medium by dramatically increasing the contact between directed light and the surrounding atmosphere.

4. Conclusions

The reaction activity of a Fiber Optic Evanescent Wave Sensor is greatly influenced by the thickness of the cladding within the sensing area of the fiber. We can say here that the sensor can be developed by partially removing the cladding material surrounding the optical fiber single-mode. The sensing theory, based on the variation of the refractive index based on the interaction of the transient field with the optically absorbed analyte, is utilized such that the thin cladding portion enables transmission loss by the vanishing waves that radiate energy from the heart as a function of the environment. It can also be claimed from the findings that the lower the cladding thickness, the greater the sensitivity efficiency of the optical fiber. In the field of environmental detection, such as water pollution, this sensor may be used.

The influence of temperature and size on the absorption coefficient of CdSe quantum dots

The influence of temperature and size on the absorption coefficient of CdSe quantum dots

Roaa Sh. Hammadand[1], Nidhal M. Abdul-Ameer[1]

[1]Department of Physics, College of Education for Pure Science-Ibn Al-Haitham, University of Baghdad, Baghdad, Iraq

E-mail: dr.nidhalmoosa@gmail.com

Abstract. Because of Cadmium selenide quantum dots (CdSe quantum dots) has a tuning energy gap in the visible light range, therefore; it is provided a simple theoretical model for the absorption coefficient of CdSe quantum dots, where the absorption coefficient determines the extent to which the light of a material can penetrate a specific wavelength before it is absorbed. CdSe quantum dots have an energy gap can be controlled through two effects: the temperature and the dot size of them. It is found that; there is an absorption threshold for each directed wavelength, where CdSe quantum dots begin to absorb the visible spectrum at a size of 1.4 nm at room temperature for a directed wavelength 300 nm. It has been observed that; when the wavelength is increasing its absorption threshold is increased. For wavelengths (400, 500, 600) nm, the absorption thresholds for each quantum sizes are (1.8, 2.2. 3.2)nm respectively. On the other hand, a rising of the temperature led to reduces the absorption coefficient value , that at 400 K for all quantum sizes, the absorption coefficient increases >2000cm^{-1}(According to the directed wavelength) than it is at 0 K. CdSe quantum dots can be considered as one of the most promising materials because it has a tuning gap for the visible wavelengthsfor different applications, such as light-emitting diodes in different colors of the visible spectrum.It is found that ;there is a good agreement between our theoretical calculations and experimental results.

Keywords: CdSe quantum dots, Tuning Energy Gap, Absorption Coefficient, Absorption Threshold

1. Introduction

Recently, CdSe quantum dots have been an intensely researched compound due to their size and shape-dependent properties arising from the quantum confinement regime [1,2]. This regime depends on the spherical particle-in-a-box model that predicts strong quantum confinement, besides it has a tuning energy gap [3].

One of the most important photometric techniques in solids is the light absorption scale, the absorption coefficient, which can determine the depth at which light of a specific wavelength penetrates a martial. The wavelengths that include the visible and the infrared are the most important wavelengths for applications. The absorption coefficient depends on the properties of the CdSe and the energy of the incident photon, whether it is greater, less, or equal to the energy gap [4]. Taking into consideration, the atomic structure and density of states of the conduction band and valence, and the type of energy

gap, whether direct or indirect [5]. Researchers have studied the absorption coefficient due to its importance, Jinjun Sun and Ewa M Goldysthey are analysis the linear absorption coefficient that due to interband transition in CdSe quantum dotstheoretically [6]C.A. Leatherdale et al usemodels of light scattering from light-absorbing small particles in CdSe quantum dots [7]. Ehud Shaviv et al. used a method to obtain-CdSe QRs concentrations are based on a comparison of the absorption far above the transition of the bandgap [8]. Other researchersas W. W. Yuetal, A. Strioloetal , O. Schmelzetal and C. A. Leatherdaleetal have studied the determination of the molar absorption coefficients of CdSe QD experimentally [9–12].

The characteristics of CdSe are highly sensitive with respect to various growth processes as well as ambient conditions [13]. Due to the importance of the absorption coefficient for its apparent effect on the optical properties, in addition to some optical constants, therefore, in this paper, we present a theoretical model of CdSe quantum dots that study the effect of temperature and the quantum dot size on the absorption coefficient.

2. Theoretical Model

The absorption rate of light is proportional to the intensity of the flux of photons of different wavelengths. When light passes through material, the flux of photons gradually decreases, so that the material absorbs some of the photons. Thus, the number of photons that will reach a given point in a CdSe quantum dots depends on both the wavelength of the photon and the distance from the surface.

Tauc relation is using to calculate the absorption spectra due to the optical transition energy, it is expressed as [14, 15]:-

$$(\alpha\, h\nu) = B(h\nu - E_g)^{\gamma} \dots\dots\dots\dots\dots\dots\dots\dots (1)$$

where B is a proportionality constant, α is the absorption coefficient, $h\nu$ is the energy of the photon, E_g is the optical band gap and γ is an indication of the type of electronic transitions, where $\gamma = 1/2$ for direct transition and $\gamma = 2$ for indirect transition.

It is known that CdSe has a direct energy gap and is characterized by direct and allowed electronic transition, therefore; Eq. (1) becomes: -

$$\alpha\,(hv) = \frac{B}{hv}\left(hv - E_g\right)^{\frac{1}{2}} \dots\dots\dots\dots\dots\dots\dots\dots (2)$$

It is important to be mentioned that; the proportionalityconstant can
Be calculated from the formula [16]:-

$$B = e^2 * \frac{\left(2 * \frac{m_e^*.m_h^*}{m_e^* + m_h^*}\right)^{\frac{3}{2}}}{n.c.h^2.m_e^*} \dots\dots\dots\dots\dots\dots\dots\dots (3)$$

where e is the electron charge, n is the refractive index is Planck's constant, m_e^* is the effective mass of electron and m_h^* is the effective mass of the hole [16].

Since we have two influences that affect the absorption coefficient in our study, the first is the temperature, so the energy gap will be calculated as a function of temperature [4]:-

$$E_g(T) = E_{g0} - \frac{\alpha * T^2}{\beta + T} \dots\dots\dots\dots\dots\dots\dots\dots (4)$$

Where α, β are coefficients fitted with experimental data for each material which equal to ($3.3 * 10^{-4}$ eV.K^{-1}, 83 K) respectively, E_{g0} is the energy gap at 0K which equals 1.834eV [4].

In terms of the change in the electron's effective mass as a function of temperature, it can be formulated with the following relationship [17]:-

$$m_e^*(T) = m_{e300}^* * \frac{Eg_{300}}{Eg(T)} \dots\dots\dots\dots\dots\dots\dots\dots (5)$$

While the effective mass of hole as a function of temperature is expressed by [17]:-

$$m_h^*(T) = m_{h300}^* \frac{E_{g300}}{E_g(T)} \dots\dots\dots\dots\dots\dots\dots (6)$$

where E_{g300} , m_{e300}^* and m_{h300}^* are the energy gap, the effective electron mass, and the effective hole mass at room temperature, respectively [17].

The other influencing factor is the size that due to the quantum confinement of an atom in three dimensions appears with characteristic electronic and optical properties [17].

In this study, we will use the Burs equation [18].

$$E_g QD = E_g(Bulk) + \frac{h^2}{8r^2}\left(\frac{1}{m_e^*} + \frac{1}{m_h^*}\right) \dots\dots\dots\dots\dots\dots\dots\dots (7)$$

where $E_g QD$ is the energy gap of quantum dot, $E_g(Bulk)$ is the bulk energy gap, r is the quantum dots' size.

To study the effects on the quantum dots of CdSe, we substituted equation (4) with the term $E_g(Bulk)$, and substituted equations (5) and (6) (which represent the change in the effective mass of the electron and the hole respectively as a function of temperature) in equation(7) to get an equation describing the energy gap of CdSe quantum dots as a function of temperature which denoted by $E_g QD(T)$:-

$$E_g QD(T) = E_g(T)(Bulk) + \frac{h^2}{8r^2}\left(\frac{1}{m_e^*(T)} + \frac{1}{m_e^*(T)}\right) \dots\dots\dots\dots\dots\dots\dots (8)$$

To obtain the absorption coefficient of CdSe quantum dots as a function of energy and temperature, we substitute the Eq. (8) in Eq. (2).

$$\alpha\,(hv, T) = \frac{B}{hv}\left(hv - E_g QD(T)\right)^{\frac{1}{2}} \dots\dots\dots\dots\dots\dots\dots\dots (9)$$

3. Results and Discussion

The occurrence of the absorption process inside the materials is described or measured by the absorption coefficient, so the absorption coefficient of CdSe Quantum Dots (eq. (9)) has been studied from; two effects the temperature, and the quantum size of dots. It can be noticed that in Figure (1) the energy gap of bulk CdSe was its highest value at 0 K., It is beginning to decreasing sharply with rising temperatures, which its highest value at 400K. The reason for this behavior is the increase in the energy of electrons due to interaction between the thermal phonons and the electrons. This lead, in fact, to an increase in the vibration inside the atom where the lengths of the atomic bonds increase, which makes them weaker with the ability to break them is easier to release the electron, which facilitates the transfer of a high-energy electron from the valence band to the conduction band and as a result of the multiple electron transitions, the energy gap decreases [19, 20].

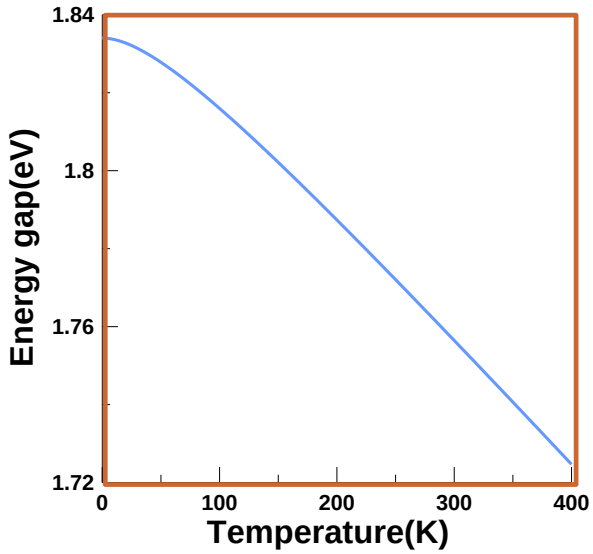

Figure 1. The energy gap of bulk CdSe decreases with increasing temperature

Figure (2) indicates the change in the energy gap due to the decrease in the quantum dot size, it is noted that; the energy gap value changes lightly when the quantum size decreases from 10 nmto 4 nm. This means that these sizes in this range are close to the behavior of the bulk. But when the size is smaller than a size 4 nm, the energy gap begins to increase very significantly until it reaches the highest values at 1 nm. In fact, that is due to the effect of quantum confinement that shifts the energy state to higher (lowest) levels at the conduction band (valence band), which increases the size of the energy gap [21,18].

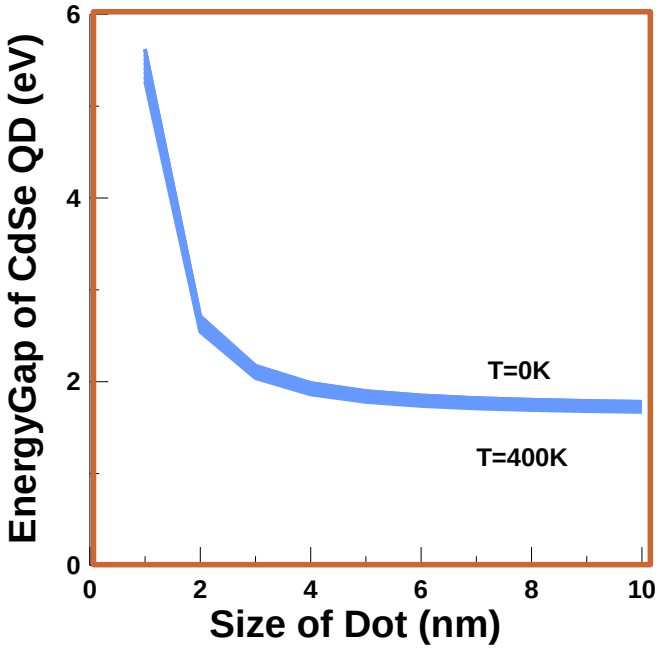

Figure 2. The energy gap of CdSe quantum dots as a function of quantum size dots

Figure (3) shows the absorption coefficient as a function of wavelengths (300nm-730nm) at room temperature. Must attract attention to two important points, the first is that; the different ranges of the

absorption coefficient are due to the different energy gaps of the quantum size of CdSe. It is noted that as the size is larger, it takes a greater range than before, where the size of 1.4 nm takes the range of ultraviolet spectrum only, while the size of 10 nm includes the range of ultraviolet, visible, and some of infrared spectrum. The other point is the energy gap which is inversely proportional to the quantum dot size of the CdSe [22, 23]. It can be seen from the figure that; the response of the quantum sizes as a function of wavelengths begins at 1.4 nm, while sizes of 1nm to 1.2nm, with a very large energy gap, do not absorb the energies of this range of wavelengths at room temperature. Where the wavelength 300nm has the highest energy is 4.141 eV, therefore; the electrons cannot cross the optical energy gap and exciting [24]. Whereas at the quantum dot size of 1.4nm, electrons able to absorb this range (λ=300 nm) of wavelengths at room temperature because it has an energy gap of about 3.571 eV. For this reason, it will allow more energy to be absorbed when the optical gap is smaller. Now, it is appropriate to explain the mechanism that causes the absorption coefficient to decrease according to the relationship$E = \frac{h*c}{\lambda}$. where the ability of the incident light energy to excite electrons from the top of the valence band to the bottom of the conduction band decreases because it does not have an energy equal to or greater than the size of the optical energy gap to excite it [25]. It can be said that; the range of quantum sizes that have been relied upon in this research from 10 nm to 1.4 nm. In this range, the absorption coefficient gradually decreases as the quantum dot becomes smaller [24, 26]. This leads us to believe that the possibility of CdSe quantum dots in tuning colors according to the size. Where the blue shifting is observed when the size of the quantum dots decreases, while red shifting is tuning when the size be larger.

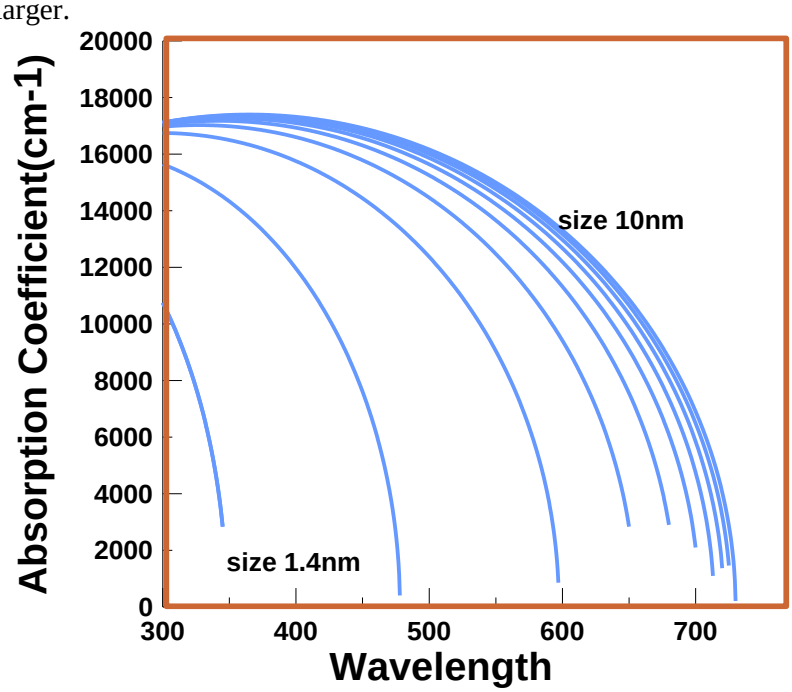

Figure 3. The absorption coefficient as a function of wavelength at the deferent size of CdSe quantum dots between from 1,4nm (absorption threshold) to 10nm.

Figure (4) represents the absorption coefficient as a function of temperature (0-400) K by fixing specific wavelengths, where it is found that the absorption coefficient increases with rising temperature [27]. This increase is evident after the temperature of 100 K at the wavelengths between 300nm to 600nm except the threshold size at the wavelength from 500nm to 600nm where the increase begins with values greater than 100 K and at 700nm after 300K With an increase in temperature, the energy gap get smaller from its usual size as a result of the vibration of the electrons with the increase in their energies, which makes them able to leave their sites and move inside the band, or if its energy

is sufficient, it can move from the valence band to the conduction band. Therefore, with increasing the contribution of the transition processes, the optical absorption coefficient increases.

Noticing Figure (4), there are several important points, the first is that; the absorption coefficient, in general, decreases as the wavelength of the electromagnetic spectrum increases. The other point, the threshold size increases with an increase in wavelength, for example, we find that the size threshold at λ= 300nm is 1.4 nm while for λ= 600nm is 3.6nm. This is because the energy of the specified wavelength is less than the value of the energy gap so that the electron transitions only respond at a size in which the energy gap corresponds to the energy of a photon of wavelength directed to it. However, the sizes of the quantum dots will be determined for each wavelength, the reason could be due to that; the energy gap be smaller and the susceptibility of incident wavelengths to the excitation of electrons [28, 29]

As a result of what was mentioned above, which is that some of the threshold sizes are unable to absorb the wavelength falling on them except at a specific temperature, as is the case at λ= 500 nm, so that the threshold appears only at a temperature of 200 K and the same is the case of λ=600nm. As for 700 nm, the 6 nm minimum appeared at a temperature of 300K, as mentioned earlier, resulting from a decrease in the size of the energy gap with higher temperatures.

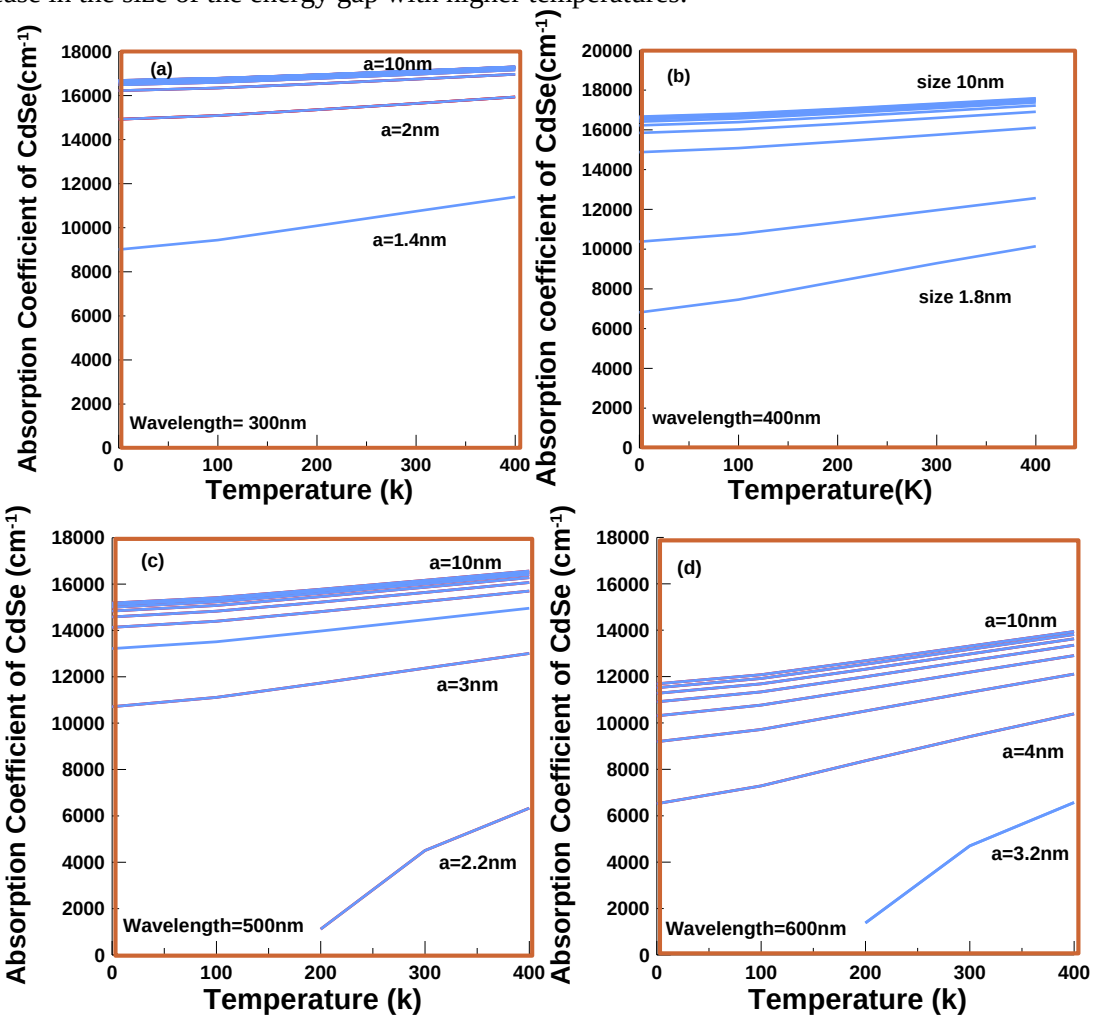

Figure 4. The absorption coefficient increasing with temperature at different wavelength, a(300nm), b(400nm), c(500nm), d(600nm).

Figure (5) shows the absorption coefficient as a function of the size of the quantum dots. In this figure, for all wavelengths, the absorption coefficient decreases with the size of quantum dot be smaller. But, for each wavelength there is a specific size that suffers a curvature then sharp descent in the absorption coefficient. For the wavelength of 300 nm, the absorption coefficient begins to decrease sharply at the size of 3 nm, while the wavelength of 400 nm, it begins at the size of 4 nm. The other wavelengths follow the same behavior according to the energy compatibility of the energy gap of the quantum dots. This behavior is attributed to the number of electronic transitions, which is almost constant at large sizes, then the transitions begin to decrease until they disappear. In fact, this confirms the existence of an absorption threshold for each specific wavelength.

On the other hand, it can be found that small quantum sizes do not react at high temperature which is due to the large energy gap arising from the quantum confinement, as compared to large quantum sizes, which show a direct reaction at high temperatures due to the small energy gap that they have.

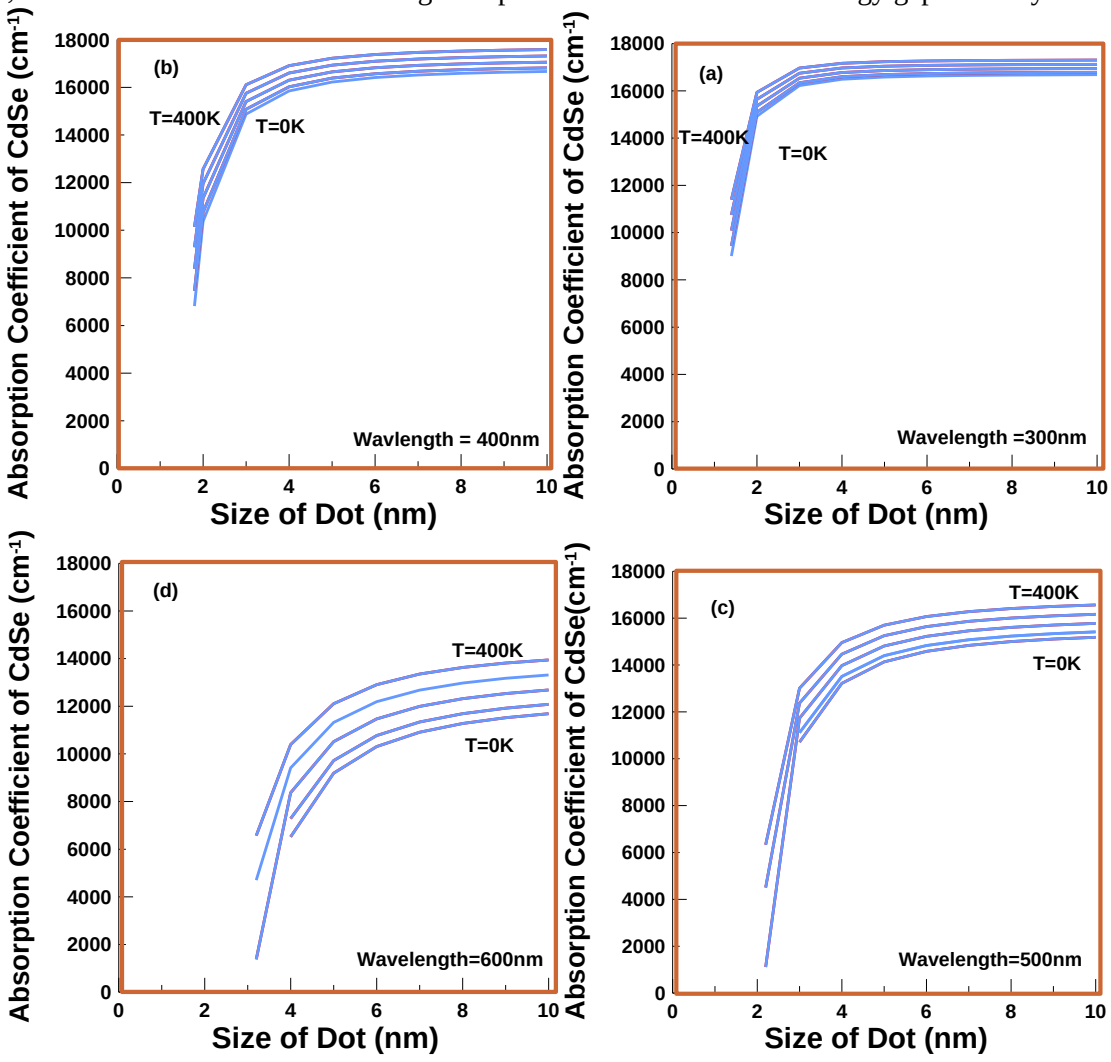

Figure 5. The absorption coefficient as a function of quantum dot size at different wavelength.a (300nm), b (400nm), c (500nm), d (600nm).

The most of experimental results review the optical absorption coefficient in the form $(\alpha\, h\, \nu)^2$. So, it is showed our calculations in the same format in Figure (6c), which gives a suitable match for both Fig.(6a) [27] which represents experimental results, and Fig. (6b) [30] which acts as theoretical models.

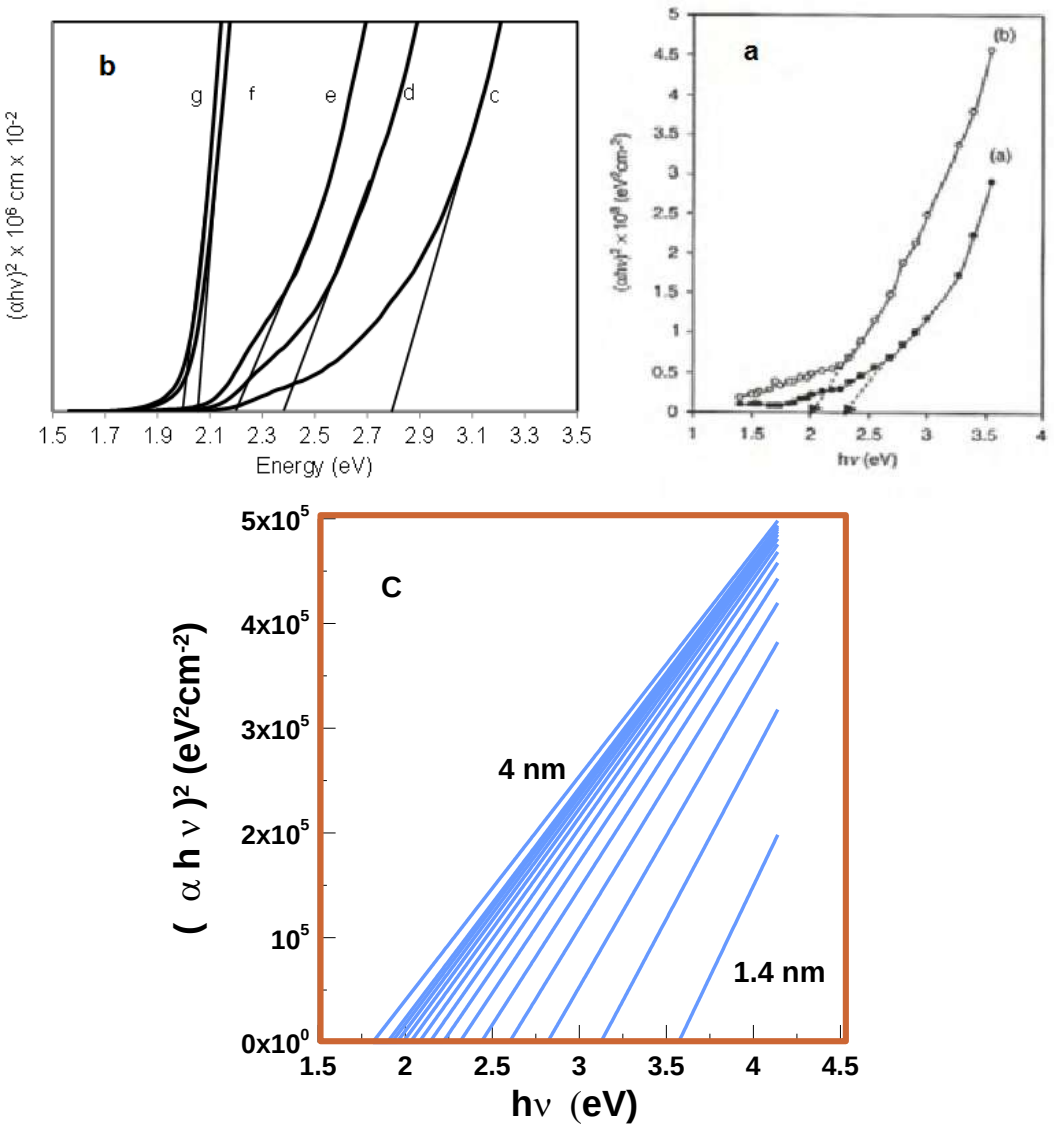

Figure 6. Absorption Coefficient of CdSe quantum dots a. experimental results [27], b. theoretical models [30], c. our calculations

4. Conclusion

For CdSe quantum dots, not all sizes are capable of absorbing electromagnetic radiation, where the absorption threshold begins in quantum dot size 1.4 nm at room temperature. Thus, CdSe quantum dots can be tuned to absorb different wavelengths according to the quantum dot sizes until they reach 10 nm which can be absorbing all wavelengths in the range of the visible spectrum. Therefore, CdSe quantum dots can be considered as one of the most promising materials for tuning energy gap applications, such as light-emitting diodes in different colors of the visible spectrum. On the other hand, each wavelength has an absorption threshold in which the energy of photon of wavelength corresponds to the energy gap of the size of the CdSe quantum dots. Also, for each specific wavelength, the absorption coefficient remains relatively constant for all quantum sizes until it reaches a size in which the energy gap does not match to the energy of the specified wavelength, where the absorption coefficient value drops sharply until it vanishes this is an indication of the end of electronic transitions in the material. All calculations were done by using software MathCAD 15.

Abstract. There is no doubt that optical fiber technology is one of the most important stages of the communications revolution at all and it is of utmost importance in our daily life. In this work, five fibers with core radii 2.5, 4.5 and 6.5–8.5 μm were designed. The properties of all guided modes have been calculated at a wavelength of 1550 nm by using RP Fiber Calculator. A single-mode fiber is obtained when the core radius approaches the wavelength. As the core radius is increased, the fiber becomes a multimode. The percentage power in the core increases with increasing core radius. The modes profiles were illustrated and compared with the modern references.

Keywords: Single-mode fiber, Multimode fibers, Step-index fibers, Guided modes, Third window (1550 nm), RP Fiber Calculator.

1. Introduction

A thin strand of glass with a higher refractive index core surrounded by a lower refractive index cladding forms an optical fiber [1]. A step-index fiber (SIF) has an abrupt index change at the core-cladding boundary [2]. Figure 1a shows a multimode (MM) SIF which allows the propagation of multiple modes within the fiber core. Figure 1b shows a single-mode (SM) SIF which allows the propagation of only one mode. The refractive index profile in both cases may be defined as [3]:

$$n(r) = \begin{cases} n_1 & \text{for } r < a \text{ (core)} \\ n_2 & \text{for } r \geq \text{a (cladding)} \end{cases} \quad (1)$$

where r is the radial position, n_1 and n_2 are the refractive indices of core and cladding, respectively and a is the radius of the fiber core. MMFs and SMFs only differ in the radius of the light-guiding core [4]. Fabrication of MMFs is easy. Further the launching of light into MMFs is also easy. These fibers are generally used for short distances, like local area networks (LANs). Launching of light into SMFs and fabrication of SMFs are difficult and so the fiber is expensive. Generally in the SMFs, the transmission loss and dispersion are very small. So the SMFs are very useful in long distance communication [5].

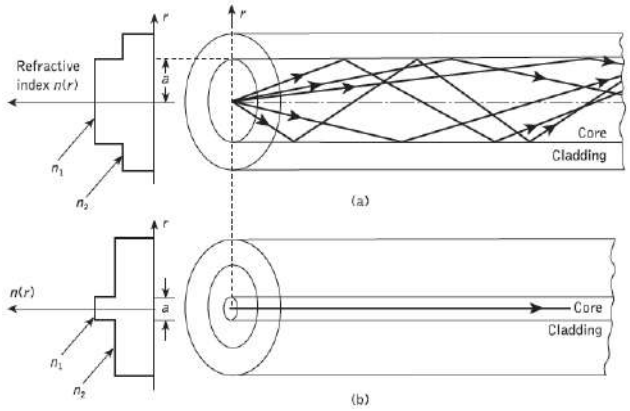

Figure 1. The refractive index profile and typical rays in SIFs: (a) MM and (b) SM [3].

In 2017, Mohammed and Al-Hindawi [6] studied and calculated the design parameters such as operating wavelength, core radius, numerical aperture, acceptance angle, attenuation, dispersion and information capacity for SIFs and graded-index fibers for different sources.

In 2018, Gulistan et al. [7] demonstrated an innovative approach to enhance mode stability by reducing mode coupling between the propagation modes of a few-mode fiber by using commercially available finite element method (FEM)-based COMSOL software.

In 2020, Salih [8] designed a SMF at 1310 nm and 1550 nm wavelengths by using RP Fiber Calculator. Also, Ibrahim and Salih [9, 10] used this program to study properties of propagated transverse modes through SIFs at 850 nm and 1300 nm.

In this work, SM and MM optical fibers have been designed and their properties were calculated at 1550 nm.

2. Theoretical Part

When the incidence angle is greater than the critical angle, the light is totally internally reflected at the core-cladding interface ($r = \mathrm{a}$). The critical angle is given by [11]:

$$\theta_{\mathrm{c}} = \sin^{-1}\left(\frac{n_2}{n_1}\right) \tag{2}$$

The acceptance angle of the fiber can be calculated by [12]:

$$\theta_{\mathrm{a}} = \sin^{-1}\left(\frac{1}{n_{\mathrm{o}}}\sqrt{{n_1}^2 - {n_2}^2}\right) \tag{3}$$

where n_{o} is the refractive index of the incident medium ($n_{\mathrm{o}} = 1$ for air).

The numerical aperture (NA) measures the amount of light that collects by or emerges from the fiber core. The NA is defined as [13]:

$$\mathrm{NA} = \sin\theta_{\mathrm{a}} \tag{4}$$

The normalized frequency is a dimensionless parameter which determines the number of modes. It is calculated by [3]:

$$\mathrm{V} = \frac{2\pi}{\lambda}\mathrm{aNA} \tag{5}$$

where λ is the free space wavelength. A fiber has the lowest loss at 1550 nm [14].

The propagation constant is given by [12]:

$$\beta = \frac{2\pi}{\lambda}n_{\mathrm{eff}} \tag{6}$$

where n_{eff} is the effective refractive index which lies within the range of cladding and core indices.

The effective area is a quantitative measure of the area which a fiber mode effectively covers in the transverse dimensions. It is defined as:

$$A_{\text{eff}} = \frac{[\int |E|^2 dA]^2}{\int |E|^4 dA} = \frac{[\int I dA]^2}{\int I^2 dA} \quad (7)$$

where E is the amplitude of electric field, I is the corresponding intensity and dA signifies integration over the whole plane.

For a Gaussian beam, the effective area is:

$$A_{\text{eff}} = \pi\omega^2 \quad (8)$$

where the radius ω can be determined from [2]:

$$\omega \approx \left(0.65 + 1.619\text{V}^{-3/2} + 2.879\text{V}^{-6}\right)\text{a} \quad (9)$$

This is accurate within 1% for 1.2<V<2.4. For V>2.405, it applies to the first mode.

There is also a modified approximate formula [12]:

$$\omega \approx \left(0.65 + 1.619\text{V}^{-3/2} + 2.879\text{V}^{-6}\right)\text{a} - (0.016 + 1.561\text{V}^{-7})\text{a} \quad (10)$$

The percentage power propagating in the core is [2]:

$$\text{P in core} = \left(1 - e^{-2\text{a}^2/\omega^2}\right) \times 100\% \quad (11)$$

The cut-off wavelength is given by [3]:

$$\lambda_c = \frac{2\pi}{\text{V}_c}\text{aNA} \quad (12)$$

where V_c is the cut-off normalized frequency for the linearly-polarized (LP) mode. For example, the LP_{01} mode has $\text{V}_c = 0$ and the LP_{11} mode has $\text{V}_c = 2.405$.

3. Results and Discussion

RP Fiber Calculator can be used to make calculations on optical fibers with radially symmetric index profiles. Inputs in this program as shown in Figure 2 are core radius, core refractive index (1.45), cladding refractive index (1.44) and wavelength (1550 nm). Outputs are: numerical aperture (NA= 0.17), normalized frequency (V), number of modes (M), properties and profiles of guided modes.

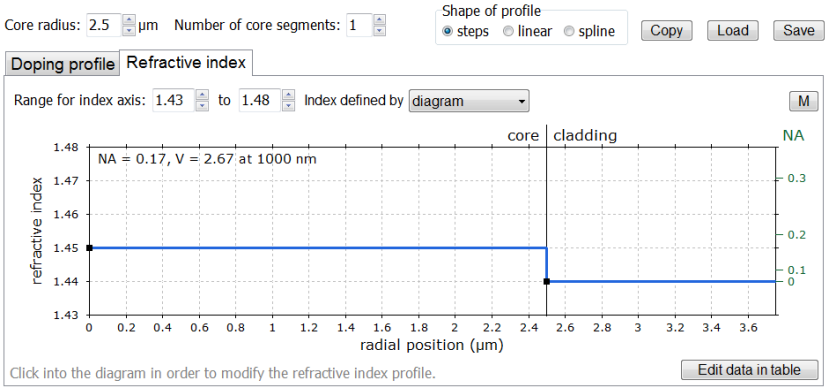

Figure 2. RP Fiber Calculator.

Table 1 shows normalized frequencies and number of modes. The normalized frequency and number of modes increase with increasing core radius. The fiber is SM when V<2.405; while at V>2.405, the fiber is MM.

Table 1. Normalized frequency and number of modes.

a (µm)	V	M
2.5	1.723	1
4.5	3.101	2
6.5	4.479	4
7.5	5.168	5
8.5	5.858	6

3.1. Single-Mode Fiber

A single-mode fiber can be obtained when the radius of the core is a small multiple of the operating wavelength. Table 2 shows LP_{01} mode properties of this fiber calculated from RP Fiber Calculator. These properties include propagation constant, effective refractive index, effective area and percentage power in the core.

Table 2. Properties of LP_{01} mode (a=2.5 μm).

β (/μm)	n_{eff}	A_{eff} (μm^2)	P in core (%)
5.84977	1.443081	38.4	64.5

Effective area and power in core for this mode calculated from Equations (8) and (11) are listed in Table 3. There is a small difference when compared with those in Table 2.

Table 3. Effective area and power in core for LP_{01} mode (a=2.5 μm).

From Equations (8) and (10) A_{eff} (μm^2)	From Equations (10) and (11) P in core (%)
39.9	62.7

Figure 3 shows LP_{01} mode profile (single spot in the 2D plot and Gaussian in the radial plot).

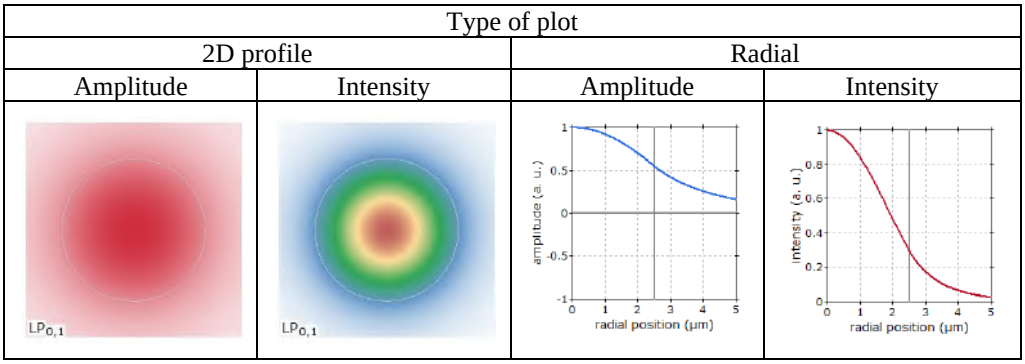

Figure 3. Profile of LP_{01} mode (a=2.5 μm).

3.2. Multimode Fibers (First Design)

Multimode fibers can be obtained when the core radius is large compared to the operating wavelength. Four core radii were compared 4.5, 6.5–8.5 μm. The properties of guided modes of these fibers calculated from RP Fiber Calculator are listed in Tables 4 to 7. From these tables, the following can be observed:

1. The mode LP_{01} has the highest β, n_{eff}, P in core and has no cut-off.
2. Increasing core radius results in increasing β, n_{eff}, A_{eff}, P in core and cut-off wavelength of the mode.

Table 4. Properties of LP modes (a=4.5 μm).

Number of the mode	Mode	β (/μm)	n_{eff}	A_{eff} (μm^2)	P in core (%)	cut-off (nm)
1	LP_{01}	5.86421	1.446643	58.4	90.7	
2	LP_{11}	5.84550	1.442028	73.2	68.8	1965.75

Table 5. Properties of LP modes (a=6.5 μm).

Number of the mode	Mode	β (/μm)	n_{eff}	A_{eff} (μm^2)	P in core (%)	cut-off (nm)
1	LP_{01}	5.87003	1.448080	97.2	96.4	
2	LP_{11}	5.85846	1.445225	95.3	89.4	2839.42
3	LP_{21}	5.84419	1.441703	117.6	75.9	1797.05
4	LP_{02}	5.84085	1.440880	143.5	60.7	1796.87

Table 6. Properties of LP modes (a=7.5 μm).

Number of the mode	Mode	β (/μm)	n_{eff}	A_{eff} (μm^2)	P in core (%)	cut-off (nm)
1	LP_{01}	5.87169	1.448488	122.5	97.5	
2	LP_{11}	5.86247	1.446213	116.4	92.8	3276.25
3	LP_{21}	5.85076	1.443325	130.0	85.0	2073.52
4	LP_{31}	5.83740	1.440030	169.1	67.7	1553.47
5	LP_{02}	5.84732	1.442476	122.5	79.1	2073.31

Table 7. Properties of LP modes (a=8.5 μm).

Number of the mode	Mode	β (/μm)	n_{eff}	A_{eff} (μm^2)	P in core (%)	cut-off (nm)
1	LP_{01}	5.87285	1.448774	150.2	98.2	
2	LP_{11}	5.86531	1.446915	140.3	95.0	3713.09
3	LP_{21}	5.85563	1.444526	150.9	89.9	2349.99
4	LP_{31}	5.84417	1.441699	163.9	81.4	1760.60
5	LP_{02}	5.85256	1.443769	133.9	86.7	2349.75
6	LP_{12}	5.83930	1.440498	208.4	61.1	1637.92

Table 8 shows a comparison between the effective refractive index differences of the last two core radii. It can be observed that the difference between LP_{21} and LP_{02} modes is the lowest. A low Δn_{eff} between the modes may result in energy loss because of the interference between the adjacent optical modes or energy transfer due to inter-mode mixing.

Table 8. Effective index differences between LP modes.

a (μm)	Δn_{eff}

3.3. Multimode Fibers (Second Design)

In order to compare the results, a second design of MMFs is considered. The core and cladding refractive indices are taken as 1.45 and 1.4403, respectively. Table 10 shows a comparison between this work and Reference [7].

Table 10. Comparison between this work and Reference [7].

	This work (second design)		Reference [7]	
Software	Free RP Fiber Calculator		Commercial COMSOL	
n_1	1.45		1.45	
n_2	1.4403		1.4403	
λ(nm)	1550		1550	
a (μm)	7.5	8.5	7.5	8.5
V	5.091	5.769	5.1	5.77

Tables 11 and 12 show modes properties for the second design of this work.

Table 11. Properties of LP modes (a=7.5 μm) (second design).

Number of the mode	Mode	β (/μm)	n_{eff}	A_{eff} (μm^2)	P in core (%)	cut-off (nm)
1	LP_{01}	5.87172	1.448496	123.2	97.3	
2	LP_{11}	5.86256	1.446236	117.4	92.5	3226.90
3	LP_{21}	5.85095	1.443373	132.0	84.3	2042.29
4	LP_{02}	5.84758	1.442542	125.9	77.8	2042.08

Table 12. Properties of LP modes (a= 8.5 μm) (second design).

Number of the mode	Mode	β (/μm)	n_{eff}	A_{eff} (μm^2)	P in core (%)	cut-off (nm)
1	LP_{01}	5.87287	1.448779	151.0	98.1	
2	LP_{11}	5.86538	1.446931	141.2	94.7	3657.16
3	LP_{21}	5.85576	1.444558	152.5	89.4	2314.59
4	LP_{31}	5.84441	1.441758	167.4	80.3	1734.08
5	LP_{02}	5.85273	1.443811	135.9	86.0	2314.35
6	LP_{12}	5.83981	1.440623	240.8	55.9	1613.25

A comparison between two designs in this work shows that as the cladding index increases slightly, the propagation constant, effective index and effective area are increased; while the normalized frequency, power in core and cut-off wavelength are decreased.

Table 13 shows an excellent agreement between the effective index differences of this work and those of Reference [7]. The second design has a lower effective index difference compared to the first design.

Table 13. Effective index differences between LP modes.

Reference [7]	124	177	199	127	151.92	213.77	230.45	137.00

There is an excellent agreement between Figure 8 and Figure 9 in terms of the number of modes and the profiles of amplitude and intensity.

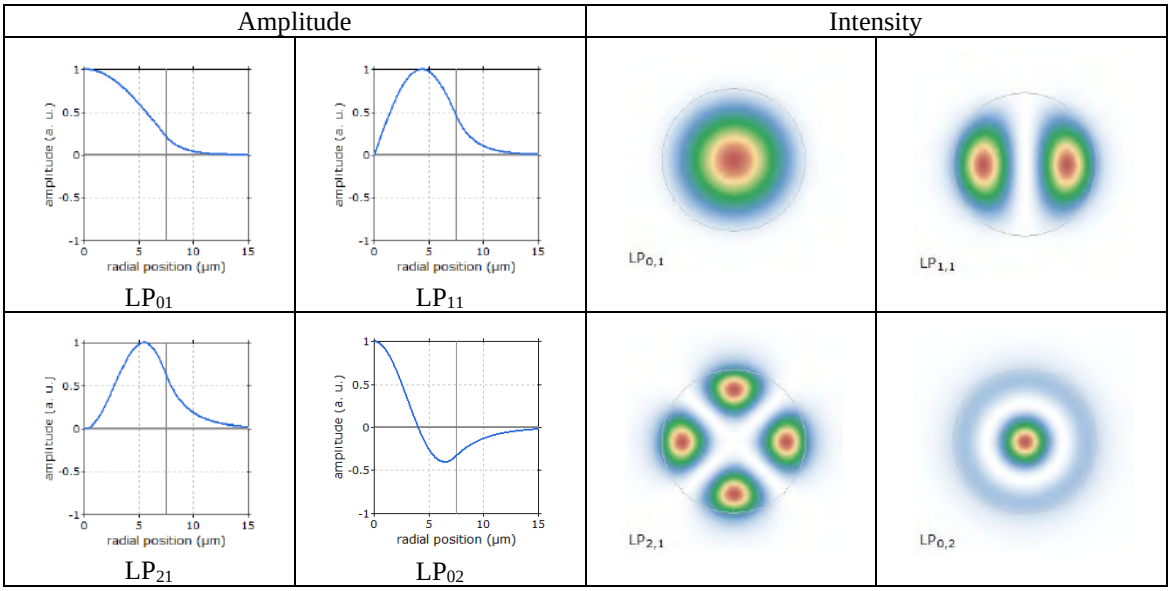

Figure 8. Profiles of LP modes (a=7.5 μm) (second design).

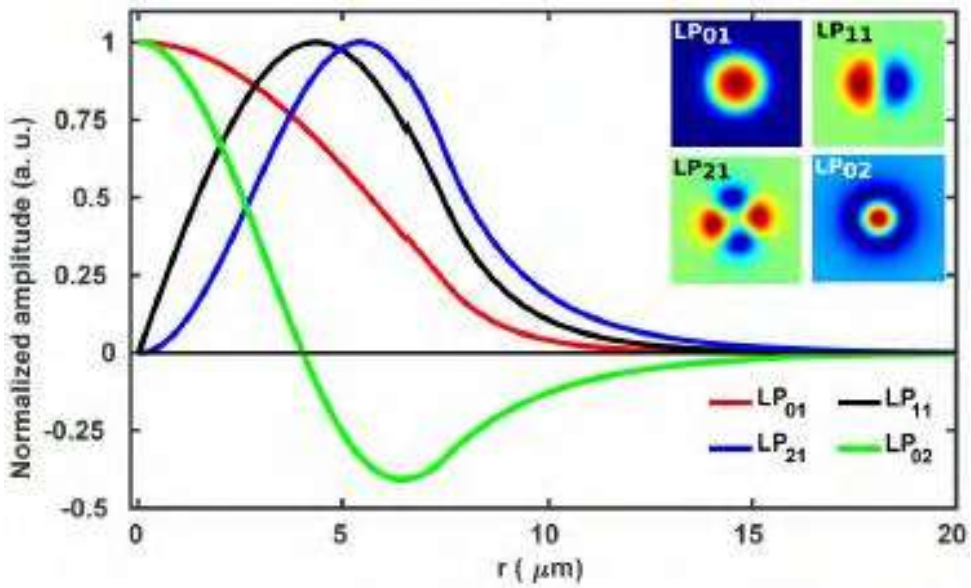

Figure 9. Profiles of LP modes (a=7.5 μm) [7].

4. Conclusions

1. If the core radius is close to the wavelength, the fiber supports only one mode. If the core radius becomes much larger than the wavelength, the fiber supports multiple modes.
2. When the core radius is large, most power is confined in the core. When the core radius becomes smaller, the amount of power in the core decreases.

Modeling the Effect of Particle Packing Density for Sintering

Modeling the Effect of Particle Packing Density for Sintering

Abstract. This research studies the effect of particle packing density on sintering TiO_2 microstructure. Sintering experiment was conducted on compacts involving of monodisperse spherical TiO_2 particles. The experimental results are modeled using L^2- Regression technique in studing the effect of two theoretical values of 55% and 69% of initial packing densities. The mathematical simulation shows that the lower values of density compacts sintered fast to theoretical density and this reflects that particle packing density improved densification rate because of the competing influence of grain growth at higher values of densities.

Keywords: sintering, densification rate, mathematical simulation.

1. Introduction

Synthesis and sintering of nanocrystalline ceramic powders have attracted much attention due to their promising properties [1, 2]. Where sintering is an essential step in the manufacturemethod of ceramic samples, which can significantly influence the microstructure and properties ofmaterials [3]. The sintering behavior and microstructural development of a powder compact is effect strongly by initial properties, for example the relative density, pore size distribution, the particle and the powder packing. Although the effect of the former parameters on the microstructural development has been examined in detail, the influence of the initial packing values of the powder has been typically over looked [4].
TiO_2 is one of the most widely used metal oxides, which has wide range of applications, including gas and humidity sensors, pigments, catalyst support, capacitors and solar cell. TiO_2 has been widely studied with respect to synthesis of nano sized powder, thin film fabrication and sintering of nano structured TiO_2 ceramics. The properties of nano structured bulk TiO_2 ceramic is pretentious by the microstructural topographiesfor example (grain size, secondary phases, porosity) and defect structure, for example (electronic and point defects) [5, 6].

Effect of particle size distribution on powder packing and sintering in binder jetting additive industrial of metals where a change of bimodal powder mixtures of several particle diameters and mixing parts were printed and sintered to study the influence of bimodal mixtures on the parts density and shrinkage. The using of bimodal powder mixtures develops the flowability (10.5%) and powder's packing density 8.2%, the increasing of the sintered density (4.0%) where reducing of the sintering shrinkage (6.4%) [7].

The intension of this study was modelled mathematically the densification rate of TiO_2 powder using L^2-Regression modeling technique utilizing two initial packing densities 55% and 69% theoretical.

2. Theoretical part

Sintering is an industrialprocedure in which a fine powder that has been formed into a form is subsequently fired at high values of temperatures. The compact when fired densifies and transform non-porous. Sintering is a treatment with thermalthat bonds particles composed into a solid, coherent construction, by means of mass transportationapparatuses occurring mostly at the atomic level. Distribution of particle size has animportant effect on the sintering procedure and on the microstructure of the sintered part. A wider of particle sizes distribution produced a higher green density and closer sintering in both metals and ceramics [8]. The pores are classified in two basic types: the first type called matrix or first- generation pore and the second type large called second-geneartion pores which originate from particle agglomeration and particle packing irregularities within the powder compact [9]. The large pores are extra difficult to eliminate large voide for two reasons. First simple kinetics dictate alonger time to fill a larger void by diffusion, second a large pore can be thermodynamically stable depending on the dihedral and pore size: grain size ratio [10].

The densification rate($d\rho/dt$) depends on the diffusion coefficient responsible for densification ($D_{lattice}$ or $D_{boundary}$) and the grain size [11].

$$\frac{d\rho}{dt} = \frac{CN_g DY^o \Omega}{kTG^L} \quad \text{.....(1)}$$

Where C is a constant related to the controlling mechanism, G is the grain size, **D** is the diffusion coefficient, Y^o is the gas / solid surface energy, **Ω** is the material volume, T is the temperature, *K* is the Boltzmann constant, N_g is the actual number of pores per grain , L is the grain size exponent, 3 for lattice- diffusion controlled densification which is used in this study [9].

In this study reported in Ref. [13]), the spherical, monodisperse TiO_2 powder was created by the hydroiysis of dilute ethanolic solution of titanium tetraethoxide. The powder was discrete in H_2O at a pH =8 utilizingprobe of ultrasonic, the dispersion was poured into polypropylene viale and the powder was allowable to settle to form concentrated sediments, these diments were collapsed into rigid compacts by the addingsolution of a 1 ***M*** $(NH_4)_2CO_3$ to the clear supernatant in the ampoules. The liquid was extracted and the sediment wasgraduallydried by air for one day, followed by drying by vacuum at 100 °C for18 h. the density of particles 3.1 g /cm^3in thecompacts waschanged to rutile 4.25 g /$cm^3$by prefiring the contracts at 780 °C for 3 h.
It was formed two types of TiO_2 compacts, with theoretical density of initial packing of 55 % and 69 %. Samples were heated in air rt of 55°C/ min to the sintering temperatures 1060 °C. The 55%dens compacts were fired at 1060 °C for times reaching from 0.05h to 8.4h. The high value of density compacts was fired at 1060 °C for times ranging from 0.017 to 1h.

The densification rate equation (1) can be written as follows [10];

$$\frac{d\rho}{dt} = \frac{C_3 D}{kTG^L} \quad \text{.....(2)}$$

Where C_3 is a constant. The equation (2) can be written as follows:

$$\frac{d\rho}{dt} = \frac{C_\rho}{TG^L} \quad \text{.....(3)}$$

Where C_ρ is the densification rate coefficient related to the working mechanisms.

3. Regression modeling technique

The equation of L^2_ regression which used in this study can be express as follows [13]:

$$X = (A^T A)^{-1} A^T b \quad (4)$$

Where A is the matrix , A^T is the transpose of matrix A , b is random observation and X the fixed part of equation but unknown.

The equation (3) can be written in integral forms as follows:

$$\rho - \rho_0 = \frac{C_\rho}{T(1-L)} G^{1-L}(t - t_0) \quad \text{.....(5)}$$

Equation (5) can be written to another form to make easier to handle with L^2_ regression formulation as follows :

$$\rho = K_1 G^{1-L} t + h_1 \quad \text{.....(6)}$$

where h_1 is the densification rate parameters, K_1 is the densification rate coefficient

$$K_1 = \frac{C_\rho}{T(1-L)} \quad h_1 = \rho_0 - K_1 G^{1-L} t_0$$

The density value was measured using model of L^2_ Regression [14].

4. Results and Discussion

The beheavior of sintering for the compacts have low –density and high -density compacts are displayed in Fig. 1 and Fig. 2, respectively. Fig. 1 displays the density results as a function of time at 1060 °C. As can be seen from the figure, the less densely packed compact staking the low green density required more time to reach theoretical density (ρ_{th} = 4.25 g /cm^3) than can be seen in Fig. 2. The calculated sintered for low densely sample ranged between 56.37 and 95.64 % , at time 300 min reach 95.64 % for theoretical density. This shows that little grain growth occurred during sintering because of the large mean pore size and corresponding lower green density , where the large pores eliminated at greatlyslower rate caused the decreasing of measured in rate of densification[8,11].

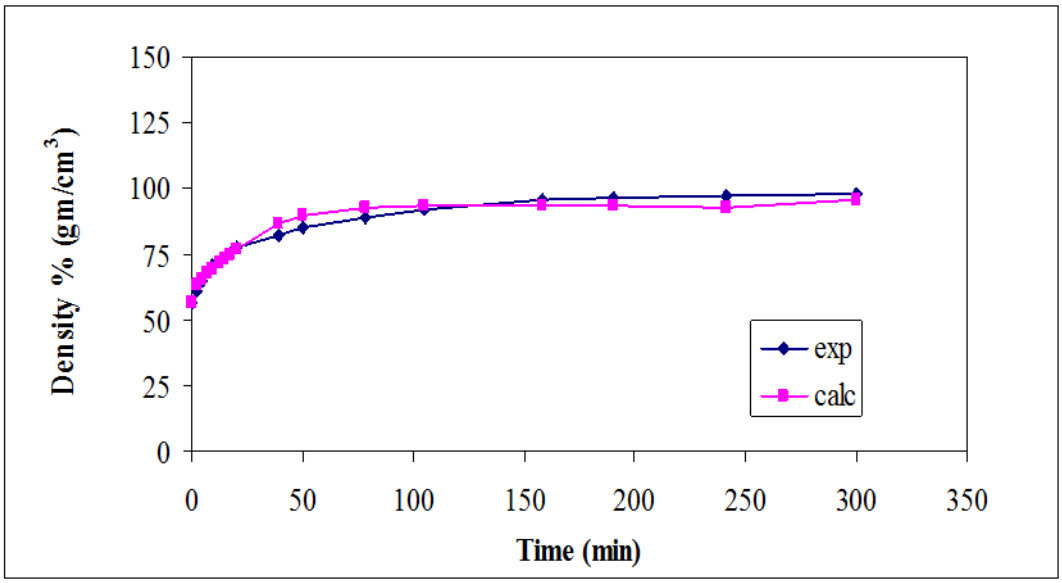

Figure 1. The density datafor 55% of theoretical densityas a function of time at 1060 °C.

The calculated sintered for high- density sample in Fig. 2 ranged between 69.12 and 98.57 % at time of 19.5 min. The increasing in packing density has resulted in animportant increase in kinetics of densification. As can be seen in Fig. 2 to reach 94% for theoretical density needs 10 min only and this has been refer to boundary of grain porosity controller of grain growth kinetics where the competing effect of grains growth occur at high density and the small pores in the green compacts were fastremoved. Sample with higher green density had a smaller mean pore size and a thinner distribution of pore size [8, 11].

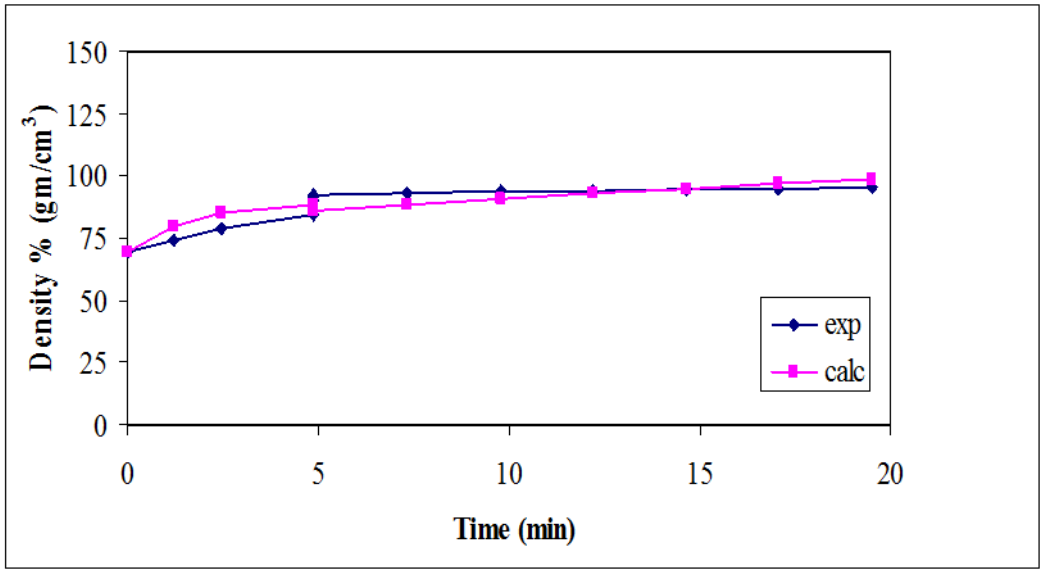

Figure 2. The density data for 69 % of theoretical density as a function of time at 1060 °C.

Fig. 3 shows the comparison for the sinteringresults for 55% and 69% of theoretical density as a function of time at 1060 °C. As can be seen, the slower rate for low densely sample (55 %) and rapidly rate for high densely sample (69 %),the sign from this that increasing the green density concurrently increases the number of pores per grains and narrow the distribution of pore size and that effect on the densification kinetics that coincide with [15].

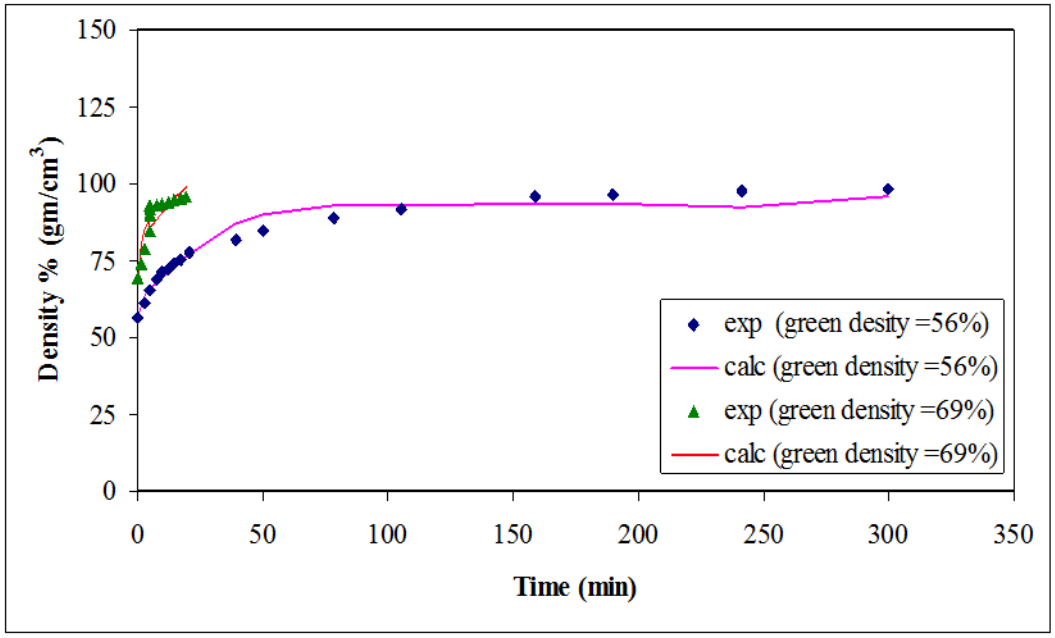

Figure 3. the density data for 55% and 69% of theoretical densityas a function of time at 1060 °C.

In Table 1, we can see the densification rate coefficient K_1 and the densification rate parameter h_1, both K_1 and h_1 for high green density (69 %) increases than low green density(55 %) because of effect of the initial partical packing and number of pores on the rate of grains growth and distribution rate .

Table 1. densification rate coefficient K_1 and Desification rate parameter h_1 for 55 % and 69 % of theoretical density.

Densification rate	55% of theoretical density	69 % of theoretical density
Densification rate coefficient K_1	61.451	80.895
Desification rate parameter h_1	0.926	2.0393

5. Conclusion

The modeling technique show that the calculated results using L^2_Regression technique agrees with experimental results ,and the samples that have more densely packed and the higher green density will sintered more quickly than the samples that less densely packed , the density ofparticel packingand

porosity uniformity were controlled of the distribution procedures. Therefor, the powder features, especially the green density control the final microstructure and the sintering kinetics.

Abstract. In this work, the bending loss was numerically studied within the COMSOL environment, where the general formula for profile index including graded and step-index types was adopted. The study showed an increase in bending loss with decreases bending radius, decreases core radius and increases wavelength. The graded order is effective up to $g = 1.75$ after which the loss is constant. There is an oscillating change in loss caused by interference between the outgoing and reflected waves from the boundaries, which becomes clearer as the loss itself increases.

Keywords: bent losses, graded-order, fundamental mode

1. Introduction

Optical fiber plays a role in high-quality and high-speed telecommunications development [1]. The loss of optical energy will occur when a fiber undergoes a macro-bend of the limit curvature radius, i.e. a dielectric waveguides lose power by radiation if their axes are curved. It has negative effect of signal for communication system of optical fiber, on this basis, it was used as a useful feature to develop optical fiber for different purposes [2]. There are two mechanisms known to cause bend-induced loss, the first happens to the uniform bend owing to mismatch between the bent regions and direct modes. The other type happens within uniformly bent region where the refractive index profile of fiber is getting as skewed, to increasing linearly of refractive index on bend. Bending affects, the individual mode various according to distinct properties such as effective refractive index, intensity, phase distribution, etc. Bending an optical fiber is to introduce refractive lose [3] So, there are many efforts to reduce macro-bending losses for all types of optical fibers along the past few years, where fiber designs were proposed to meet several requirements for macro-bend losses [1, 4]. The limitation of the most serious to its validity is caused by dealing with undistorted field of the straight guide for its derivation, even if the loss of radiation is ignored, the field changes its form in the curved guide. Therefore, no existing formulae for modeling bend-losses of these fibers were presented, except for maximum or minimum prediction of the bend loss conditions in relation to parameters of fiber and wavelength. Bending loss of fibers are employed with many important purpose like a great importance for modern communications, especially with regard to techniques of multiplexing in the way to enhance the ability to send information, plays a central role with the design of fiber amplifiers and with a fiber laser to reduce

higher-order to achieve single of effective regime of multi-mode fibers [5, 6, 7]. It has been shown in this work, that the effect of the four chosen parameters, spatially graded-order (g), wavelength of propagated wave (λ), core radius (a) and bending radius of a dielectric wave guide on the bending-losses (L_b) will be illustrated.

2. Methods

The wave front in the optical fiber must be perpendicular to the direction of propagation. The signal transmitted in core becomes faster than in cladding. As a result, loss in the signal transmitted energy through the optical fiber will appear where the speed of light must be increased as shown in Fig.1.

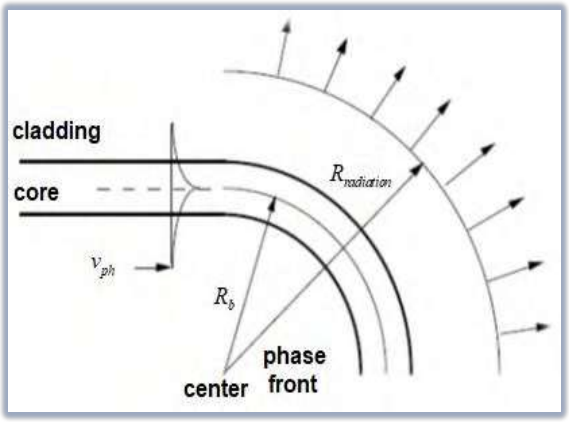

Fig.1. Bending effect of an optical fiber [8].

The total losses of a bent fiber include transition loss and pure bend loss in bent section caused by mismatch between bent and straight sections of the propagation. A single mode bent fiber of length (L), the pure bend loss calculated: [8].

$$L_b = 10 \log_{10}[\exp(2\alpha L)] = 8.686\, \alpha L \quad (1)$$

Where α = macro-bending loss coefficient (function of optical fiber structure and material, bending radius, and wavelength of radiation used in the fiber). So, there are many approaches have been employed for evaluation it, a simple formula firstly proposed by Marcuse. The simplified formula for the bent optical fibers needs to be modified to include fiber stress by utilizing the effective bend radius. Therefore, the modified index distribution must be presented by transforming the circularity curved fiber to equivalent straight fiber. This leads to, the tilted index distribution with respect to original. An increasing away from the center of the bend (curvature of the bent fiber can be a tilted refractive index), as shown in Fig.2.

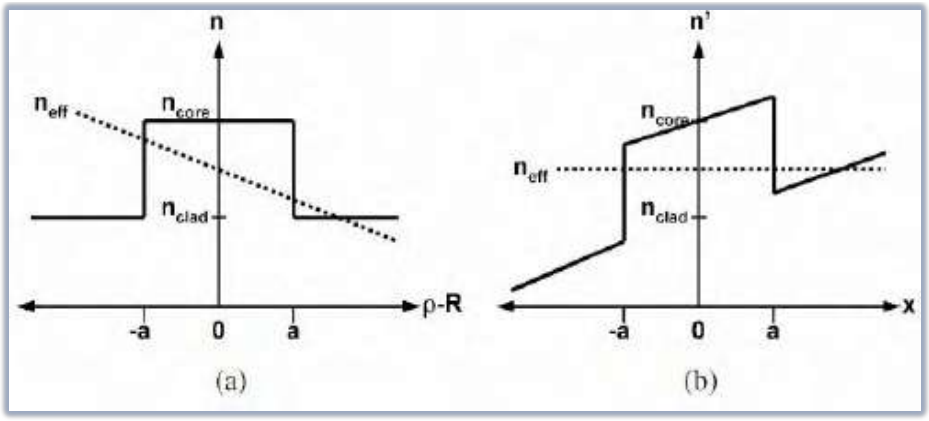

Fig.2. profile index, a) with bent and b) without bent

The well-known formula of modified refractive index distribution with slow bent ($R \gg x$) as the first approximation read as:

$$n_{equ}(x,y) = n_{mat}\,(x,y)\exp(x/R) \approx n_{mat}\,(x,y)(1 + x/R) \quad (2)$$

Where x is the displacement from the core center in curvature axis, R radius of bent and n_{mat} is the refractive index-profile to unbend fiber. Because of compression along fiber's inner half, towards the bend center and tension along the outer half of fiber, n_{mat} becomes vary according to the relation [9].

$$n_{mat.}(x,y) = n(x,y)\left[1 - \frac{n^2(x,y)\;x}{2R}[P_{12} - \nu(P_{11} + P_{12})]\right] \quad (3)$$

where $P_{11}\ and\ \mathrm{P}_{12}$ = components of photo-elastic tensor, ν = ratio of Poisson and $n(x,y)$ = the refractive index-profile of the unbend (straight) fiber and so called profile-grading, defined as [10], [11] .

$$n(x,y) = n_{core}\sqrt{1 - 2\Delta(\rho/a)^g} \quad (4)$$

where $\rho = \sqrt{\mathrm{x}^2 + \mathrm{y}^2}$, the parameter $\Delta = (n_{core} - n_{clad})/n_{core}$, n_{core} and n_{clad} = refractive index in center of the core and the cladding, respectively, and g = graded-order, it plays an important role when waves propagated the optical fiber and gives a strange properties depending on the profile indices of the different graded orders that shown in Figure 3. Accordingly, graded-order will be an important issue to construct the bent losses.

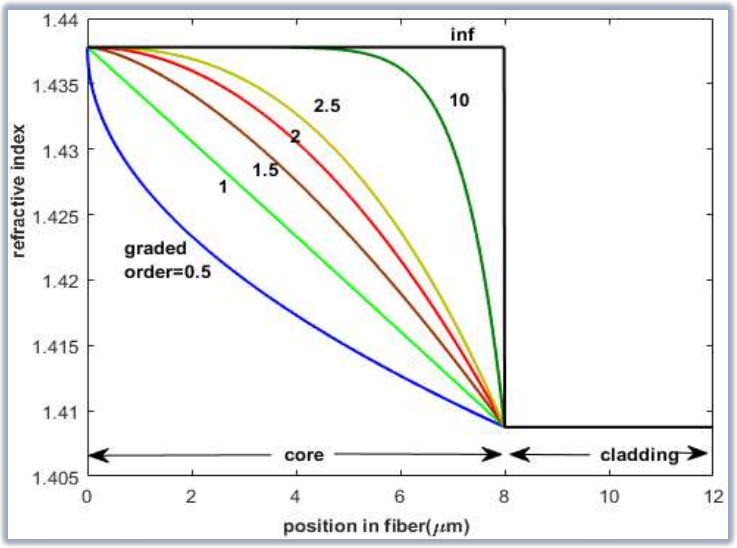

Fig.3. Refractive index profiles for different graded-orders [10]

Where 2α is the coefficient of power loss, $\kappa = \sqrt{k_{core}^2 - \beta_z^2}$ and $\gamma = \sqrt{\beta_z^2 - k_{clad}^2}$ = field decay rates of core and cladding, respectively, k and β are the propagation constants for free space and the guided mode in the unbent waveguide, respectively, $V = \sqrt{\kappa^2 + \gamma^2}$ = the normalized frequency, $K_{m\pm1}$ = Bessel function of 2nd kind.

3. Results and Discussion

COMSOL environment was used to determine the relationship between wavelength and effective refractive index. COMSOL works on a finite element method (FEM) basis which is built on the basis of dividing the cross section into small parts and forming the mesh. A perfectly matched layer (PML) is added with thickness as a third layer to the geometry to avoid the reflections from cladding interface to interfere with the mode confined in the core. We applied boundary condition of the perfect electric conductor, with zero initial conditions, to the exterior boundary. Concerning profile index, the same formula as in Eq.(4) with the replacements (by and by) were applied. The type and accuracy of the mesh are chosen in order to achieve better accuracy with a suitable operating time for the computer. A study of this subject requires controlling of four factors: the core radius, the bending radius, the wavelength and the graded order. Fig.4 represents a selected sample for the fundamental mode in step index fiber by changing part of these factors. It is evident that the amount of energy that will be outside the core is subject to these factors.

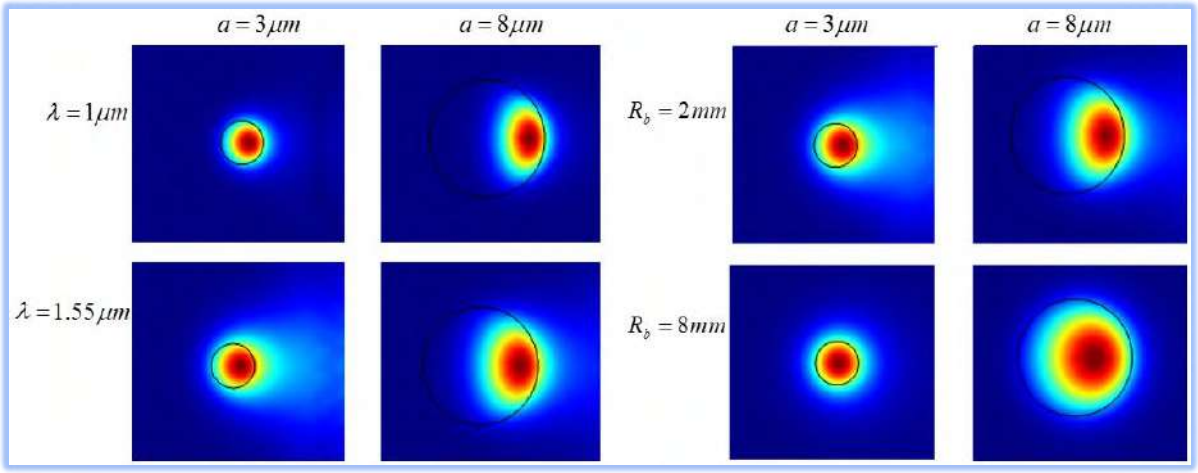

Fig.4. Fundamental mode at $g=\infty$ for (a) $R_b=2mm$ and (b) $\lambda=1.55\mu m$

Fig.5 represents the relationship of the bending losses with the graded, where core radius is at $a=10\mu m$. Generally, the loss decreases with the graded order until reach the limits of $g \geq 1.75$, then the loss is constant. That is, the type of profile index affects only the loss at the smaller graded orders. When the graded order decreases, the distribution width of the profile index will be small. Therefore, the Gaussian distribution of the fundamental mode may have a greater width, and therefore we expect the mode portion outside the core to be large with a decrease in the graded order. On the other hand, the loss is greatly reduced as the bending radius increases and vice versa. The reason for this decrease is due to the fact that a greater portion of the propagated pulse will be outside the core with a decrease in the bending radius.

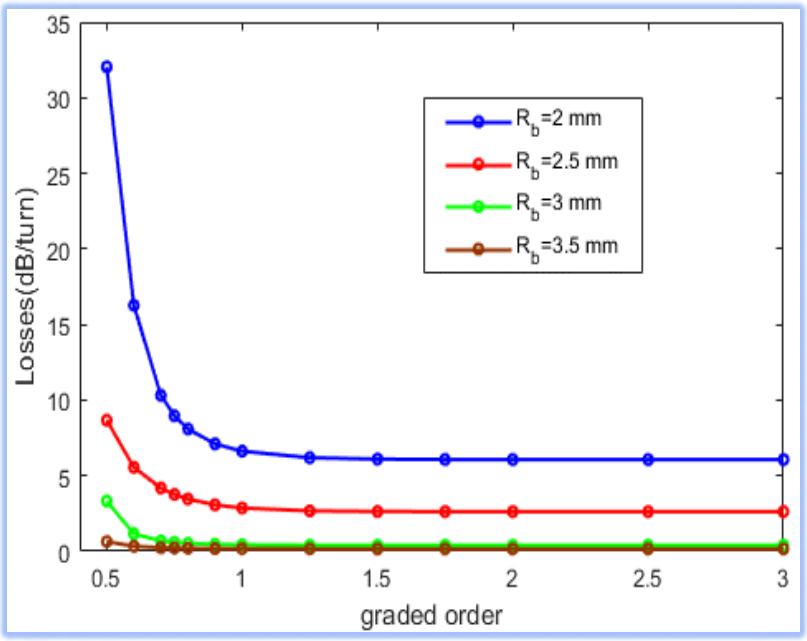

Fig.5. Bending losses and graded order

Fig.6 presents bending losses of the step index fiber as function of core radius for different values of R_b at $\lambda=1.55\mu m$. 3dB is the maximal variation when a radius is *2mm*. At a small bending radius, the

random variations appear very clear due to the increased interface section between the cladding and the PML layers. As the bending radius increases, loss and corresponding random variations will be decreased. In addition, at a small core, the loss is significant and vice versa. This is due to the inability of the core to confine the propagated pulses (small core).

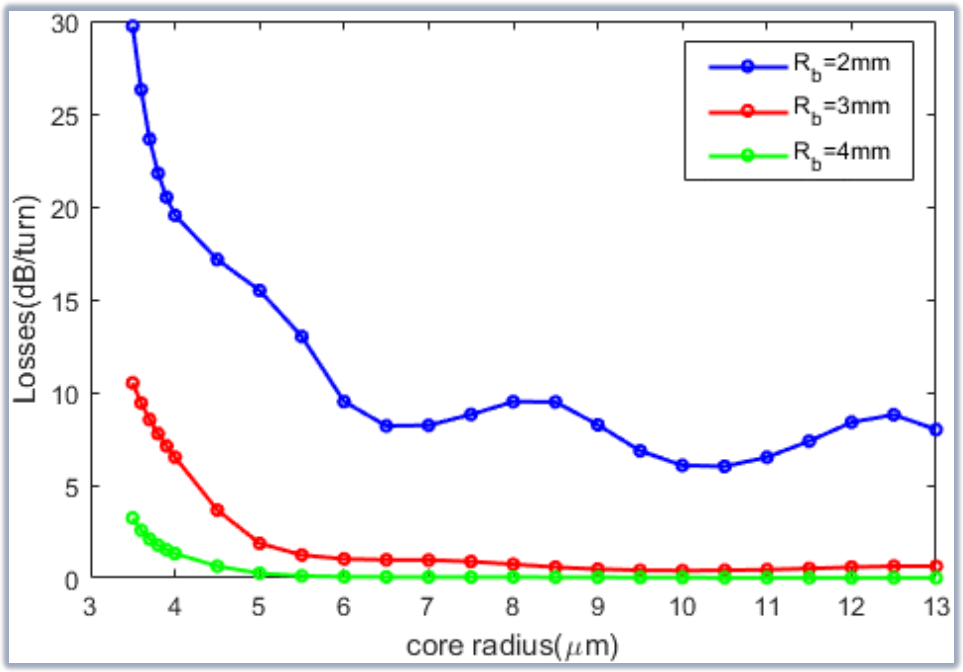

Fig.6. Bending losses Vs. core radius

Fig.7 illustrates bending losses of step index fiber as function of core radius for different wavelengths at $R_b = 2mm$. It is evident that the greater wavelength causes more losses, and the losses generally decrease with an increase in the core radius. Random variation is very clear in the case of large losses, and the interpretation of that is the same as what was mentioned in Fig.6. The greater loss at large wavelengths is due to the difficulty of confinement of the propagated pulses, especially for the small core radius.

Fig.8 explains the bending losses of the step index fiber as function of λ for core radius at $R_b = 2mm$. A smaller radius causes the largest bending losses, and the losses, generally, increase with wavelength due to a decrease in the confinement opportunity for the greater wavelengths. At small core radius, the random variations are also appeared very clear. This behavior may change when the selected bending radius is changed during the simulation, where the largest losses effects appear with a smaller bending radius.

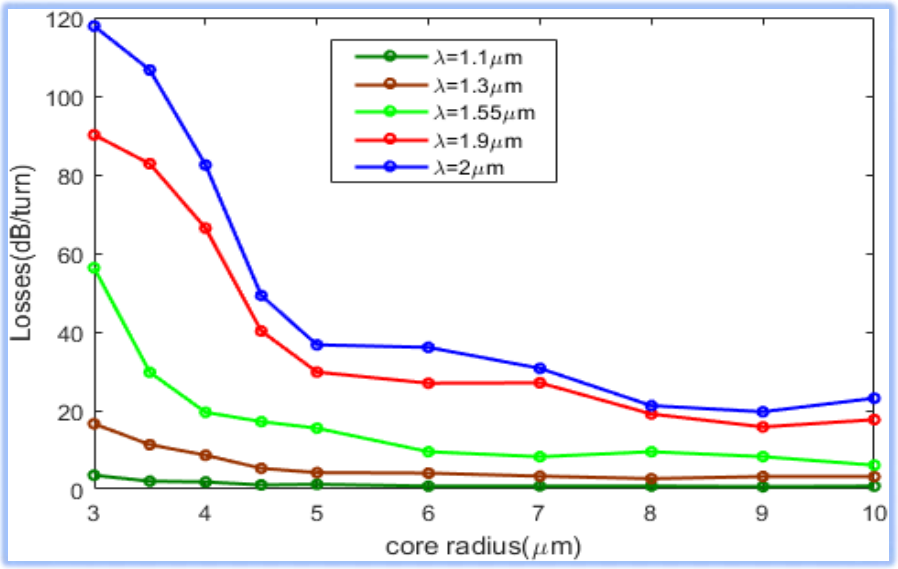

Fig.7. Bending losses Vs. core radius

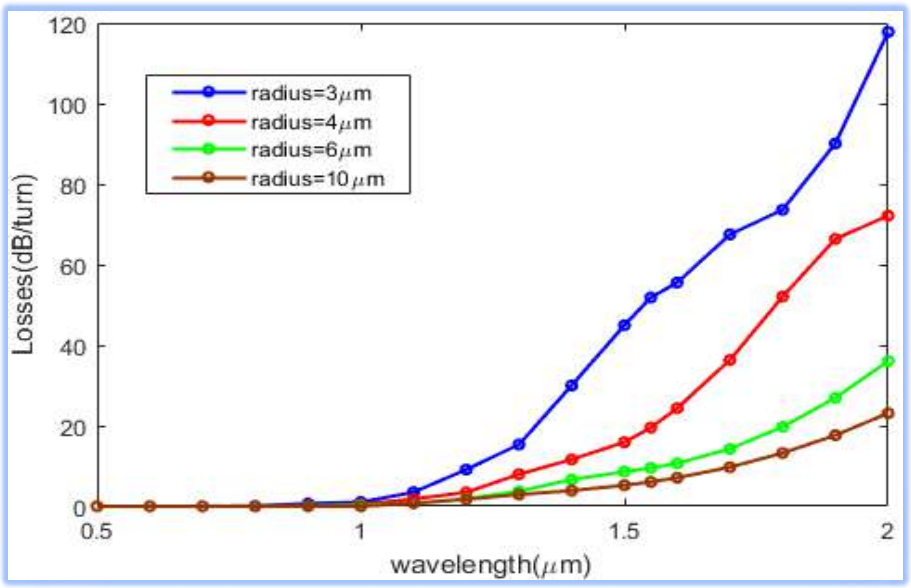

Fig.8. Bending losses Vs. wavelength

Fig.9 explains the bending losses as a function of R_b for different values of graded orders at $\lambda = 1.55\mu m$, $a = 10\mu m$. Notice that, the most significant effects appear at $g = 0.5$ and decrease with increasing graded order. Generally, the effects are closely related to each other, with graded orders values in the limit $g \geq 1$. Generally, after $R_b = 4mm$, the bending losses are very small for all graded orders and this is due to a decrease in the mode portion that will be outside the core with an increase in the bending radius.

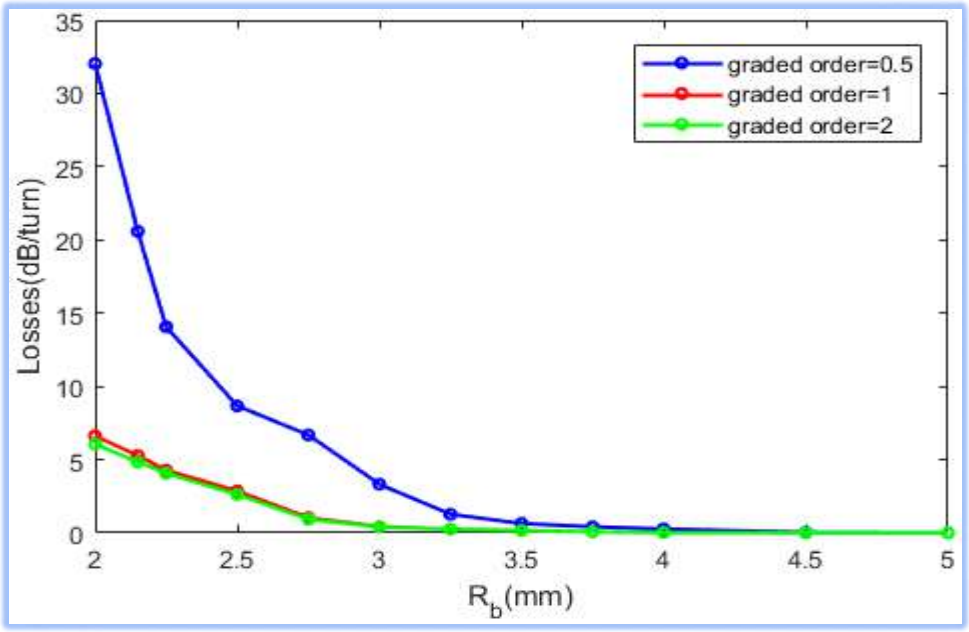

Fig.9. Bending losses as a function of R_b

4. Conclusions

In conclusion, a part of the fundamental mode may be outside the core, its amount depends on the simulation coefficients, which can be chosen to minimize the bending loss. It would appear that decreasing the bending radius and core increase loss, while loss increases with the wavelength. The loss decreases with the graded order, then it is fixed after $g = 2.5$. There is an oscillating change in the loss, which increases with decreasing of bending radius or core radius and the increase of wavelength.

The effect of acidic treatment of carbon fiber on denture mechanical properties

The effect of acidic treatment of carbon fiber on denture mechanical properties

Abstract. The purpose of this research is to increase the mechanical properties (impact and flexural strength) of acrylic polymethyl methacrylate (PMMA) denture base resin by incorporated treated and coated woven carbon fiber (WCF). To increase the roughness of fibers, WCF treated with para-aminobenzoic acid (PABA), ($C_7H_7NO_2$) at 3 different concentration treatments (0.10, 0.15, and 0.20 M). In order to make the samples appears with good aesthetic and bonding, WCF was coated with β-Tricalcium phosphate (β-TCP) powder with (0.08, 0.10, and 0.12) weight fraction (wi) in addition of using polyvinyl alcohol (PVA) at 0.01 wi, respectively. After 10 days of water storage at room temperature, the specimens have been tested via using the Charpy effect measuring system and three-point bending tests. The mechanism of interfacial interaction between β-TCP and woven carbon fibers was investigated by field emission scanning electron microscopy (FESEM) and Fourier transform infrared spectroscopy (FTIR). Based on the obtained results, when specimens contained treated and uncoated woven carbon fiber with a high concentration of (PABA), the impact and flexural strength were higher than pure sample but have a bad aesthetic. Further, (PMMA) reinforced with coated and treated woven carbon fiber as hybrid composites recorded very high raises in the mechanical properties when the concentration of (PABA) and (β-TCP) was increased, with a good aesthetic.

Keywords: Denture base, PMMA, PVA, Tri calcium phosphate, Woven CF, PABA.

1. Introduction.

Poly methyl methacrylate (PMMA) is the most successful candidate among many materials to fabricate denture base resin [1], due to its reasonable quality, low weight, excellent esthetic properties, and ease of processing and polishing and repair [2-4]. However, PMMA is not considered as a perfect material, because, its brittleness, inferior mechanical and physical properties, low modulus of elasticity, high coefficient of thermal expansion and low sorption, low flexural strength, and low impact strength [5,6]. These drawbacks of PMMA lead to the fracture, which is the most common problem of denture base resin [7]. There are many causes for fracture of the dentures, such as impact fracture usually occurs when a patient is coughing that pushes the dentures out of the mouth or accidentally dropping the dentures on the surface during the cleaning of dentures. Also, flexural failure of denture occurs when the concentration of stress around the micro cracks formed in the material due to the continuous applied of small forces [8]. Numerous methods have been developed to enhance the mechanical and surface properties of the acrylic resins. It was suggested that the introduction of synthetic fibers to the monomer/polymer is strengthening the result acrylic resin. Various fibers and powders such as carbon fiber [9,10], glass fiber [6, 11], aramid fiber [12], polyethylene fiber [13], zirconium oxide ZrO_2 nano-

particles [14] and kaolinite powder ($Al_2Si_2O_5(OH)_4$) [15] were used as reinforcements for denture base material. However, because of weak interface between fiber and resin affecting the mechanical properties, these fibers break-up the homogeneous matrix of acrylic resin. To avoid this problem, several studies have been reported in the literature that recommends surface treatment of fibers and incorporation ceramic powder such as (TiO_2, and TCP) [16] or metal oxides such as (MgO, and ZnO) [17].

In light of above notices, the research was considered to determine how mechanical properties (impact and flexural strength) of acrylic resin can be enhanced by the use of carbon fiber reinforcement and whether surface treatment affects the impregnation of fiber within the resin matrix. Hence, the purpose of the study is to determine some mechanical properties (impact and flexural strength) of PMMA resin, and studying the influence of woven carbon fiber (treated and coated) on impact and flexural strength with good aesthetic.

2. Experimental details

2.1 Acidic treatment:

Fig.1 displays untreated carbon fiber in woven form. Woven carbon fibers (product No: CR160K, weight 600 g/m^2, thickness: 0.333 mm, Japan) were cut into (70×50 mm^2).

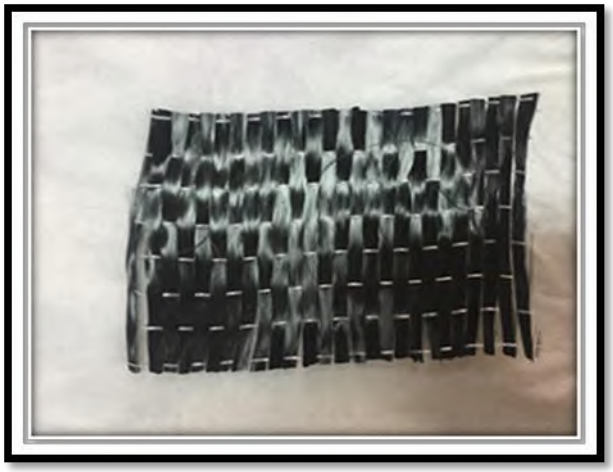

Figure 1. Untreated carbon fiber in woven form.

The woven carbon fiber was impregnated in ethanol for 15 minutes to remove contaminates, and then they were put on filtering paper, therefore put in an oven at 50 ◦C for 30 min, for drying. To make an acidic solution, (3 g) benzoic acid (3-Amino benzoic acid, $C_7H_7NO_2$, pure, minimum Assay: 98 %, New Delhi-110002, India) was dissolved in (100, 150, 200 ml) of distilled water, and left for 20 min on the magnetic stirrer. The woven carbon fiber immersed in an acidic solution for 3 hours. Once the immersion time ended, the fibers were rinsed thoroughly with distilled water to remove acidic influence. Finally, the woven fiber was dried in an oven at 70 ◦C for 2 hours.

2.2 Coating of carbon fibers

Dark carbon fiber coating with tri-calcium phosphate: different weight proportions of Tri-calcium phosphate average size (43.31nm), as presented in Table 1, were mixed with (10 ml) of distilled water and left with continuous stirring. PVA was added to the β-TCP solution with heating (Hot plate with a magnetic stirrer, BOECO-Germany), until the solution became cloudy. The coating solution was added

to fibers and left overnight in order to dry. This coating technique gave the fibers a white color on their surface. Fig. 2 referred to carbon fiber after coating.

Figure 2. Woven carbon fiber after coating.

2.3 Preparation of the flask

Denture base samples were fabricated by using a special flask as illustrated in Fig.3. The flask consists of two parts: upper and lower. The kaolin piece (70×50×3 mm) was placed in the lower part. Next, the dental stone powder was mixed with water and poured the stone to fill the flask. The inner surface of each part of the flasks was coated with Vaseline to keep the dental stone from binding to the flask. The flask was hitting several times to remove bubbles, which may be found inside the stone. The final set of the dental stone, the flask left for 15 min for hardening, and then the flask opened carefully and removes excess kaolin and stone. The obtained flask was shown in Fig. 3.

Figure 3. Flask of samples.

2.4 Preparation of the samples

Thirteen groups of test specimen were prepared by the heat-cured of PMMA, consisting of powder and liquid (methyl methacrylate, MMA) (2 g/1 ml) according to the manufacturer's instructions. In a clean and dry mixing jar the powder was mixed with liquid (MMA) and allows each powder to be wetted by monomer and left until it reaches a consistency appropriate for packing, during this time, the cover should be positioned over the mixing jar to prevent monomer evaporation and left to stand at room temperature for (12-16) min until reached to the dough stage, as shown in Fig. 4. For the unreinforced dough (G1) was placed in the mold directly. For the reinforced samples (G2-C13), the MMA has been used to wet woven carbon fibers with and without coating for 2 min. The dough was cut into two sheets; woven carbon fiber was placed between halves of the dough. Hydraulic pressure was applied to the flask slowly to 1Ton for 5 min. before the polymerization reaction. Then immerse the flask in cold water and waiting until water boiling. The resin was cured in boiling water for 1 h according to the manufacturer's instructions. When polymerization was completed; the molds extracted from water and left to cool at room temperature. The test samples were smoothed with 400,600 and 800 silicon carbide paper under tap water to remove excess materials, and then cut into specific dimensions to all tests. Before testing, all test samples were stored in water at 37°C for 10 days. All specimens were shown in Fig. 5.

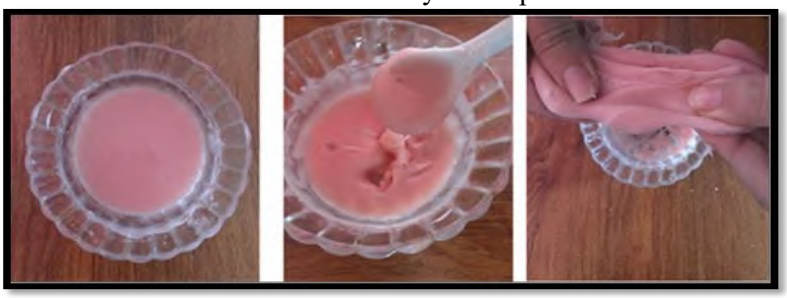

Figure 4. The dough stage.

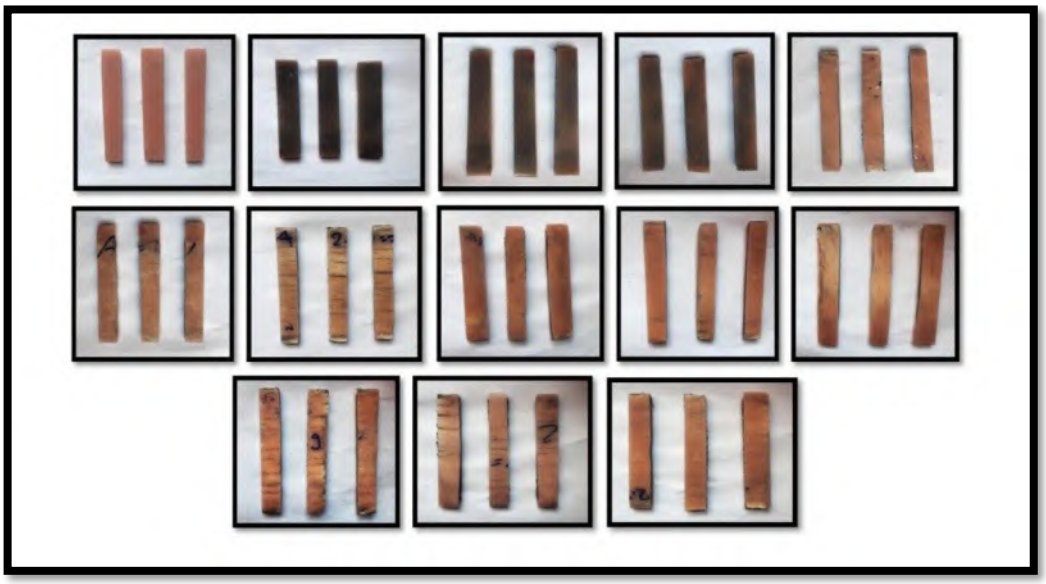

Figure 5. Fabricated samples.

2.5 Structural properties:

2.5.1 Fourier Transform Infrared Spectroscopy (FTIR):

The FTIR spectra of untreated and treated carbon fibers with para-aminobenzoic acid were recorded in the range of 400-4000 cm^{-1} by using an FTIR machine (SHIMADZO IRFFINITY) to identify the functional groups in untreated and treated fibers.

2.5.2 Field Emission Scanning Electron Microscopy (FESEM):

The surface microstructure of untreated and treated, with and without coating woven carbon fiber was examined utilizing Field Emission Scanning Electron Microscopy type (MIRA3 TESCAN-XMU).

2.5.3 Mechanical properties:

Impact strength and flexural strength were performed with utilizing the same methods in reference [15].

3. Results and discussion

3.1 Fourier Transform Infrared Spectroscopy (FTIR)

The FTIR was used to analyze surface functional groups of woven carbon fibers. The FTIR spectra can provide precise information on the material surface functional groups of untreated and treated WCF via benzoic acid. Fig. 6 shows the FTIR spectra of untreated and treated WCF using (0.10, 0.15, and 0.20 M) PABA. The spectrum of untreated carbon fiber shows a peak at 3429 cm^{-1} attributed to O-H stretching vibration of the absorbed water on the fiber surface and followed by another adsorption around 2962 cm^{-1} attributed to the stretching vibration from saturated hydrocarbon C-H [18]. The band near 2366 cm^{-1} dedicated to C≡C stretching peak, the characteristic peaks at 1722 cm^{-1}, 1637cm^{-1}, and 1230 cm^{-1} represent to C=O stretching peaks, C=C stretching, and C–N stretch peak respectively [19]. When compared untreated with treated WCF, some new peaks can be observed for treated carbon fiber. In any concentrations of PABA, WCF was recorded amine functional group in the FTIR spectrum. Peaks at 3423 cm^{-1} (0.20 M), 3451 cm^{-1} (0.15 M), and 3624 cm^{-1} (0.10 M) denote the N-H functional group,

stretched as a result of the vibration of the amine group. The characteristic of the oxygen function existed in C=O stretching, which appears at 1647 cm^{-1} for three concentrations, while C–O stretching appears at 1249 cm^{-1} peak when WCF treated with (0.20 M) and (0.15 M) while disappearing at (0.10 M) concentration. The oxygen content increased via increasing the concentration of PABA [20]. The most intensity is related to the C–N recorded at 1174 cm^{-1} when WCF treated with (0.15 M) [21]. In the preparation of biocomposites, WCF treated by PABA is essential; liquid chemical oxidation through PABA makes it an efficient technique to change the inert surface of WCF.

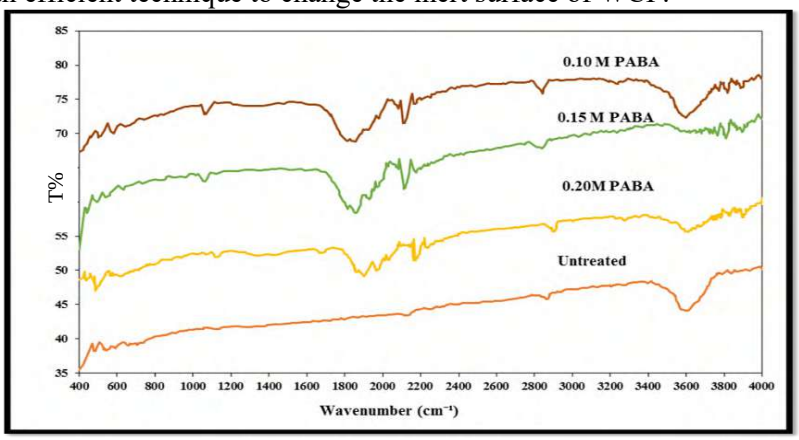

Figure 6. FTIR of WCF before and after treatment with PABA.

3.2 Field Emission Scanning Electron Microscope (FESEM)

Fig. 7a shows the surfaces of untreated woven carbon fibers appear smooth without any impurity. FESEM examination for the treated and coated surface of woven carbon fiber was imaged. The FESEM photographs of treated and coated fiber show regular and perfect spherical crystal nanostructures particles have been grown as individual clusters with few agglomerates over the surface of WCF. It can be shown that the β-TCP coating has grown homogeneously and the adhesion between the fiber and the β-TCP coat has improved. The cause for such adherence is due to the functional group of para aminobenzoic acid that has been created in carbon fiber. Fig. 7c and d showed the higher density of the functional groups of PABA results in an increase in the roughness of the surface of WCF, thus the interfacial chemical bonding strength between coatings /fiber and the resin was improved. It is assumed that the increased roughness of the fiber can enhance a mechanical interlocking effect between the fiber and the coating; this description is in accordance with Tao et al [22]. Fig. 7e shows the average particle diameter of β-TCP was 43.31nm with a spherical shape.

a b

c d e

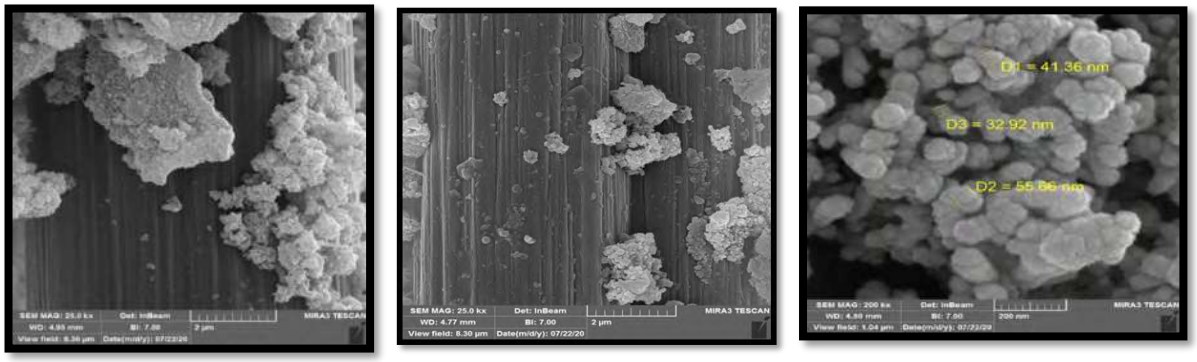

Figure 7. FESEM of (a): untreated and uncoated of CF (b) CF treated at 0.10 M of PABA and coated with β-TCP (c) CF treated at 0.15 M and coated (d) CF treated at 0.20 M and coated (e) β-TCP particle.

3.3 Impact strength

Table 2 illustrates the impact strength findings for the control group, and samples developed with treated WCF with PABA. All samples have the same fiber content (0.04 wi) and are treated with different concentrations of Para- aminobenzoic acid (0.10, 0.15, 0.20 M).

Table 2. The impact strength values for control group and treated WCF.

Group no.	Impact strength (KJ/m^2)
G1	8.05
G2	5.3
G3	9.51
G4	9.87

The control group recorded impact strength of 8.05 KJ/m^2. Lowest value of impact strength is observed in G2 when compared with the control group. The impact strength decreased with lower PABA concentration at 0.10 M, it is known that the mechanical properties depend on the bonding and interface between fiber and polymer. In G2 the surface of carbon fiber is smooth as shown in FESEM micrograph 7 b, leading to poor initial bonding between fiber and matrix. For this reason, G2 gave poor interfacial regions, hence recorded low impact strength. The highest impact strength was recorded when the fiber was treated via (0.15 M, 0.20 M). From this result, the impact strength increased with higher PABA concentration. This is because the roughness of carbon fiber surface occurs in higher acidic concentration, resulting in good bonding between carbon fiber and matrix. Despite the rise in the impact strength of the composites, the aesthetic-related result is negative.

Table 3 display the impact strength values of coated and treated WCF with β-TCP and PABA acid respectively.

Table 3. The impact strength values of coated and treated WCF.

Group no.	Impact strength(KJ/m^2)
G1	8.05
G5	6.9
G6	7.3
G7	7.8
G8	10

G9	11.13
G10	16.61
G11	15.6
G12	17.45
G13	20.23

For (G5, G6, and G7) samples prepared by treated WCF with PABA concentration (0.10 M) and coated with β-TCP (0.08, 0.10, and 0.12 wi) respectively, the impact strength values decreased when compared with G1. This decrement is because a bad bonding among coating, fiber, and the matrix, due to the poor acidic treatment of WCF. After treatment CF with the dilute solution still smooth as shown in FESEM micrograph (7 b), the bonding strength between carbon fiber, β-TCP powder and a matrix is poor. Groups G8, G9, and G10 are related to samples reinforced by treated WCF with (0.15 M) of PABA concentration and coated with (0.08, 0.10, and 0.12 wi) of β-TCP. The addition of any content of β-TCP powder at any weight fraction leads to increases in the value of impact strength when comparison with G1. One can explain that the β-TCP coatings presence, varying the CF surface characteristics into hydrophilic, highly enhances the interfacial bonding strength via the direct adhesion to matrix [23]. The treatment of carbon fiber by PABA concentration (0.15 M) had a positive effect on impact strength. This is because of the interfacial shear strength between matrix and fiber is high. The impact strength of hybrid samples papered by treated woven fiber with a concentrated solution of PAPA and coated with different weight fractions are illustrated in Table 3. The concentrated solution with the increment in the amount of β-TCP has a positive influence upon the impact strength values as depicted in (G11), (G12), and the value of impact strength raised from (15.6 KJ/m^2) to (17.45 KJ/m^2). For (G13) having a high content amount of β-TCP (0.12 wi), the impact strength increased to 20.23 KJ/m^2 by (151%) as compared with control group G1. That's perhaps owing to the reason that the β-TCP powder possesses a much higher strength of fracture in comparison with the PMMA resin [24]. Besides, the increment in the content of β-TCP raises strength. This is an anticipated result of the better adhesion of matrix and powder, and thus a higher permissible stress level transfers to CF through the loading. Mixing PVA with β-TCP powder enhance the mechanical properties of coatings because of its compatible structure and hydrophilic properties [25].

3.4 Flexural Strength

The flexural strength of acrylic resins is known to be the predominant form of clinical failure. The results of the flexural strength values in current study appeared as shown in Table 4, which shows a comparison between a pure sample and samples reinforced with carbon fibers treated with an acid solution at varying concentrations. The flexural strength of control group is 70.55 MPa, while samples prepared carbon fiber treated with a concentrated acid solution tends to be more efficient and has the maximum flexural strength value in G4. The explanation for this improvement is the etching process that produced apparent roughness of the surface fiber. The presence of roughness helped increase the area of the interlocking surface between the fiber and the matrix, which encourages the movement of stress from the matrix to the carbon fiber and therefore increased of the flexural strength. The researchers agree with this conclusion are Panigrahi, and Powel [26], Bismarck and Mohanty [27]. Eventually, a carbon fiber crack brings the test specimen to a complete fracture. This fact suggests that the tensile strength of the carbon fiber is part of the test specimen's flexural strength [28].

Table 4. Descriptive data of flexural strength.

Group no.	Flexural strength (MPa)
G1	70.55
G2	76.93
G3	81.9

G4	82.35

Flexural strength values for reinforced PMMA with treated and coated carbon fiber hybrid samples were summarized in Table 5. In current study, the flexural strength in G7 was significantly better than control group G1, while other samples recorded findings for the flexural strength less than the pure sample. The reason may be due to the weak bond between the coating and the resin, which gives low values of flexural strength. The bending strength was higher after the introduction of treated carbon fibers with concentrations of PABA at (0.15 M) and (0.20 M) and also coated with different ratios of β-TCP when compared with the pure sample. The increment in the flexural strength findings by using woven carbon fiber treated with and with 0.15 M of PABA (G8, G9, and G10) are (19.44, 17.5, and 15.09) % and fibers treated by 0.20 M of PABA (G11, G12, and G13) are (22.7, 19.77, 18.08%), respectively when compared with control sample (G1). This enhancement is due carbon fiber has a high transverse strength, and also the surface treatment by immersing the carbon fiber in a PABA acid solution increased the formation of voids or pits on the surface of the fibers. This results in an increment in the fiber surface area, thus raising the strength of bond between the matrix and the fiber. Also, process of moistening fibers with the monomer before introducing them to the resin, this process strengthened the adhesion between fiber and resin. This improvement in flexural strength is attributed to the direction of the fibers, which means that the denture base polymer with woven carbon fibers is a very significant factor in orientation [28]. After coating the treated carbon fiber, F.S. is increased compared to control sample. The β-TCP coating was dense and firmly bonded to WCF, which enhanced the interface's physical bonding. The improved interconnection can efficiently transfer the load from the CF to the matrix. For the ceramic WCF reinforced, the fiber-matrix composites are the principal load-bearing, and therefore, the flexural strength is enhanced. It can be observed the optimal flexural strength was at (0.12 wi) of β-TCP. Moreover, the existence of (0.01 wi) of PVA in the reinforcement layer will cause to improve the flexural strength due to PVA has good tensile strength, high flexibility, and good hardness [25].

Table 5. The flexural strength for denture reinforced with woven carbon fiber.

Group no.	Flexural Strength (MPa)
G1	70.55
G5	62.85
G6	67.85
G7	76.7
G8	81.2
G9	82.9
G10	84.27
G11	83.71
G12	84.5
G13	86.6

4. Conclusion

Polymethyl methacrylate PMMA has successfully been reinforced with treated WCF by 0.10, 0.15, and 0.12 M of PABA and coated with 0.08, 0.10, and 0.12 wi of β-TCP. It can be concluded that the optimal acidic treatment for woven carbon fiber is (0.20 M) PABA concentration and the recommend weight fraction of β-TCP is (0.12 wi), which resulted 20.23 KJ/m^2 in impact strength test and 86.6 MPa in flexural strength test. This could be due to treated WCF with para-aminobenzoic acid improved the adhesion between fibers/ β-TCP powder and resin. Specimens of PMMA prepared by incorporation of β-TCP into woven carbon fiber have a good aesthetic. The results of the FTIR spectrum show the content

of oxygen functional was increased after acid treatment which leads to the enhancement of the mechanical properties of the fibers. The FESEM micrographs show that acid treatment increases the surface roughness of woven fibers.

Abstract. In this paper, a 3% of polyvinyl alcohol PVA polymer solution was prepared with distilled water. PVA:Ag Nanocomposites were prepared by adding different concentrations of silver (Ag) nanoparticles (3, 6 and 9) %. Pure as well as PVA:Ag nanocomposites films were prepared by drop casting method. The optical properties of PVA: Ag nanocomposite were studied using the absorption and transmittance spectrum measured at wavelength range (200-1000) nm. The optical parameters of the prepared PVA: Ag nanocomposite, such as absorption coefficient, refractive index, and extinction coefficient, as well as the real and imaginary part of the refractive index were calculated as a function of Ag NPs concentration. The results show that the absorption edge is red shifted towards long wavelengths after adding the silver nanoparticles as well as an increment in the optical parameters after adding the Ag nanoparticles. The energy gap was also calculated for all the prepared samples, which were decreased from 4 eV to 1.72 eV with the increase addition of Ag nanoparticles content (3 to 9) %.

Keywords: PVA polymer, nanocomposite, nanoparticles, optical properties

1. Introduction

"Nanocomposites are composites in which at least one of the phases shows dimensions in the nanometer range (1 nm = 10–9 m)" [1]. Nanocomposites exhibiteda new technology besides business opportunities for all industry sectors, also it is environmentally friendly [1]. Generally, the nanocomposite class of organic/inorganic materials is a fast developing area for research. [2]. The combination of nanosized inorganic particles and polymer into a single material has fan-out a new zone in materials science that has extraordinary outcomes in the development of multifunctional substances[3]. The application of materials in nanoscale and nanocomposites which contain nanoparticles is an emanated area of nanoscience and the technology. The nanoparticles have an exceedingly surface: volume ratio. That so they usually show unique considerably and different chemical, physical, and biological properties comparing to their macro scaled counterparts [4]. Polyvinyl alcohol (PVA) is a polymer that has backbone of carbon chain attached with hydroxyl groups. PVA is not toxic, soluble in water synthetic polymer, which is used widely in the polymer blends because of its good chemical and physical properties, forming film with excellent characteristics,

emulsifying capability, and biodegradable, no carcinogenic and biocompatible qualities. These peerless characteristics enable PVA polymer in applicability in the pharmaceutical fields, surgical structures material, drug coating agents, and cosmetic industries [5]. It is well finder that polymers, which act as dielectric materials, are sterlingly host matrices for encapsulated nanoparticles metal like gold, silver, copper, and so on, as well as they act both as reducing besides capping agents and provide stability environmentally and chemically. That embedded nanoparticles NPs inside the polymer matrix will affect the characteristics of the host itself. Particularly, the polymer and the metal hybrid like polymer: Ag nanoparticles composites is overgrown functional materials in several scopes like mechanical, optical, electrical, antimicrobial, and thermal properties [6].

2. Experimental Part

In this paper, the polymer solution was prepared by adding the polymer in powder form to distilled water, and the solution was placed on a magnetic stirrer device for two hours with a temperature of 30 ° C .After the end of mixing, the solution was passed on filter paper to get rid of the sediments suspended in the solution and get a clear solution.Silver nanoparticles were added to the solution at different concentrations of 3, 6, and 9 % to study their effect on the optical properties of the polymer. PVA:Ag Films were prepared by drop casting method on glass substrate cleaned in three steps by using HCl, ethanol, acetone and ultrasound device. The optical properties of pure PVA and doped with Ag nanoparticles were studied by using the UV-VIS spectrophotometer in the range (200-1000) nm.

3. Results and Discussions

The optical absorption retrofitted useful information about band structure of solids, electronic, and phononic states. During the processes of optical absorption, the incident photon with certain energy excites an electron from the lower state to occupy a position in a higher energy state. By investigating the changes in transmitted radiation, the types of possible transitions for an electron can be concluded. The fundamental (main) absorption indicates to band-to-band (or to excitation) transitions. The main absorption shows by a fast elevation in absorption, which named as absorption edge which is used to determine the optical energy band gap [7].

When a beam of light affecting the material surface, part of the incoming beam which that not reflected by the material will be transmitted or absorbed through the material. Lambert-Beer law clear that the fraction of light ray that is absorbed is a function of the thickness for the materials also the way that the photon interacts with materials structure [8].

$$I = I_0 \, e^{(-\propto x)} \qquad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Whereby, (I) is the intensity of light beam that coming out of the material, (I_0) is the intensity of the incident light beam,(x)is the path where the photon moves, and (α)is the absorption coefficient, which is a material characteristic.

Fig.1 shows the absorption spectrum of prepared films as a function of wavelength. The absorption increased with increasing the concentration of Ag nanoparticles. There is a relation between the position and shape of the spectral absorption peak with particle size and the morphology of the metal nanoparticles, so the spectral analysis will be the effective method to explain the spectral properties in metal nanoparticles [8]. The absorption peaks were between (392 and 477) nm where the maximum value was at 415 nm, which is the exemplary Plasmon Resonance Band (PRB) of AgNPs [9]. The peak and the location show that the ions of Ag+ in $AgNO_3$solution were successfully reductive to AgNPs.

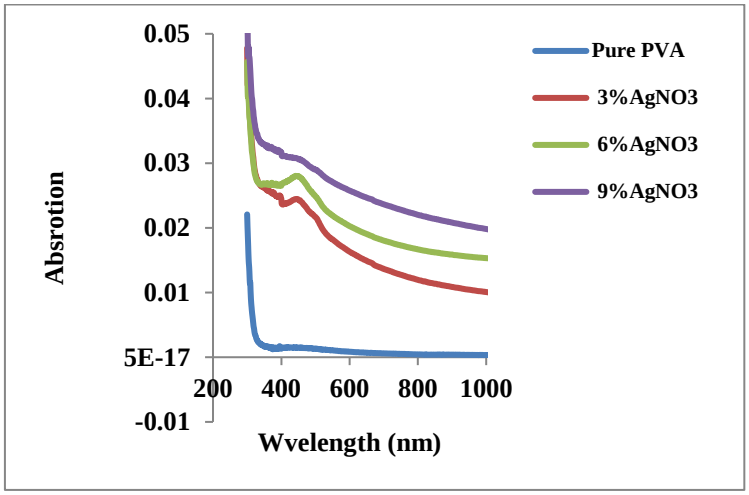

Fig.1. Absorption spectrum as function of wavelength for pure and doped PVA

From Figure 1, one can see that the absorption increases generally with increasing the ratio of dopant. This increasing explained the existence of interaction between Ag nanoparticles with PVA and getting a new structures for PVA:Ag composites. The increasing in the ratio of Ag nanoparticles leads the edge of UV radiation absorption to zaps towards region of longer wavelength for all the samples especially for the concentration of 3 and 6% weight percentage of Ag[10].

The coefficient of proportionality in equation (1) is defined as absorbance coefficient, and it a measure to how strong samples absorbs light at a specific wavelength [11].

The absorption coefficient (α) can be determined by the equation [12]:

$$\alpha = \frac{2.303\,A}{t} \quad \ldots\ldots\ldots\

R + T + A = 1 ……..……(3)

Besides that the transmission is very low but the reflectivity is very high compared with absorption and transmission and this is shown by Fig. 3 and 4.

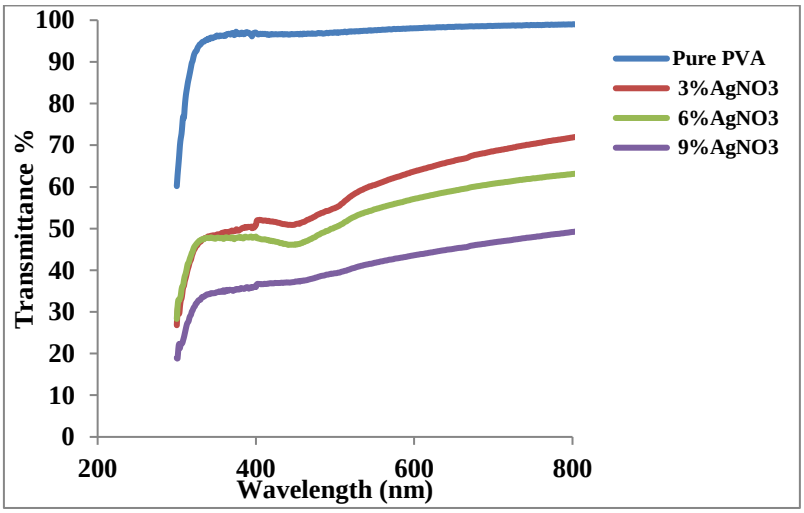

Fig. 3. Transmittance as function of wavelength for pure and doped PVA

The clear transparency of visible light is a particularly trait of the inorganic/polymer nanocomposite especially at dipped concentration, when the aggregation of NPs is constraining. The observation of irregularity in UV absorption spectrum by the nanocomposites of high loading Ag nanoparticles may be because of the elastic scattering of the arrival UV light upon the samples. This could be happened when the size of particles are smaller than wavelength λ_{UV} (190-400 nm) [10].

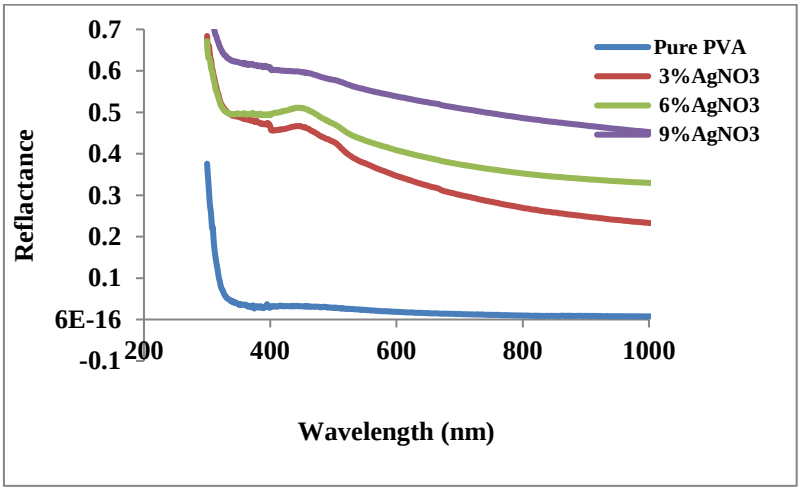

Fig.4. reflectivity as function of wavelength for pure and doped PVA.

The most significant optical constant is the refractive indexwhich depends on the wavelength of the electromagnetic wave. The electromagnetic wave lost some of its energy during the propagation throw a medium. Knowing that the real part n is the refractive index and the imaginary part Kis the extinction coefficient [15]. Refractive index of an optical or dielectric medium (N) can be calculated by dividing the light velocity in vacuum c on its velocity in the medium v′ (N = c/v′). Complex refractive index N, can be obtained by equation (4) [16].

$$N=n+ik \quad \ldots\ldots\ldots\

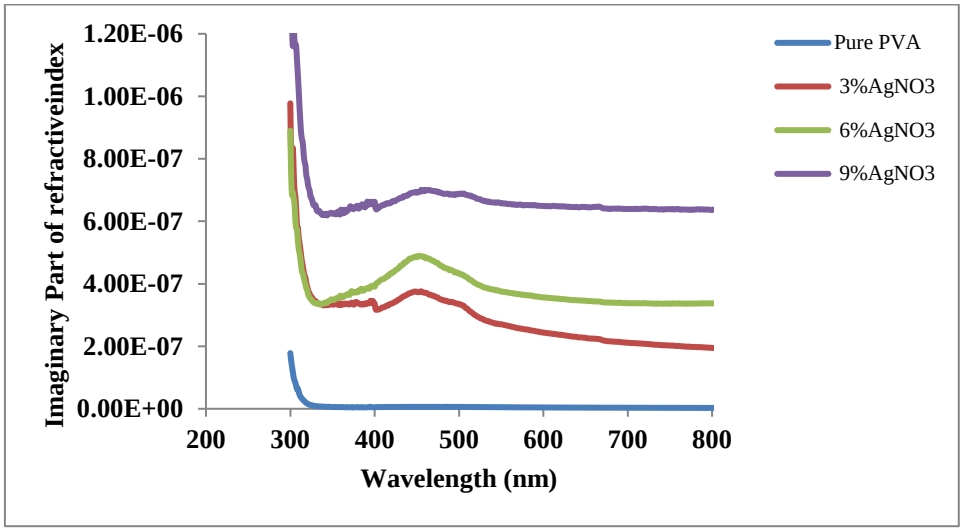

Fig. 7. Imaginary part of refractive index as function of wavelength for pure and doped PVA.

The dependences of real and imaginary parts on the photon energy for all samples were clear in Figs. 6 and 7. Figs. 6 and 7 signifies that εr>εi because the mainly depends of them on n2 according to equation (8) and that is way because the extinction coefficient (K) was extremely small so it could be neglected. The imaginary part depending on extinction coefficient is due to the equation (9) because the value of the refractive index is very small [13]. The real and imaginary parts in Fig. 6 and 7 show that an increasing after doping, which indicates that the samples were not have similar structure. For this the change in the concentration of doping lead to change in chemical composition for polymer [12].

The optical conductivity of a material is the frequency response of the material when it is irradiated by light [18]. The optical conductivity (σ opt.) is mainly based on the optical parameters such as optical absorbance,
reflectance and absorption coefficient. The refractive index (n) with absorption coefficient (α), were used to obtain the optical conductivity (σopt.), using the following relation [19]:

$$\sigma \text{ opt} = \frac{\alpha n c}{4\pi} \quad \ldots\ldots\ldots\

Where (B) is a constant, (r) is an empirical index, and it is equal to 2, 3, 1/2 and 3/2 relied on the nature for electronic transition responsible of the absorption. The drawing for the value of product of absorption coefficient by the photon energy $(\alpha h\nu)^{1/2}$ via photon energy ($h\nu$) at room temperature, induction for liner portion of this curve to a point $(\alpha h\nu)^{(1/2)}=0$ gave the value of the optical energy band gap to films of pure PVA and doped with Ag NPs which can be considered as an evidence for indirect transition .The value of energy gap are showed in table (1).

Table (1) Energy gap values for pure and doped samples.

Samples	Energy gap (eV)
Pure PVA	4
PVA:Ag(3%)	2.11
PVA:Ag(6%)	1.95
PVA:Ag(9%)	1.75

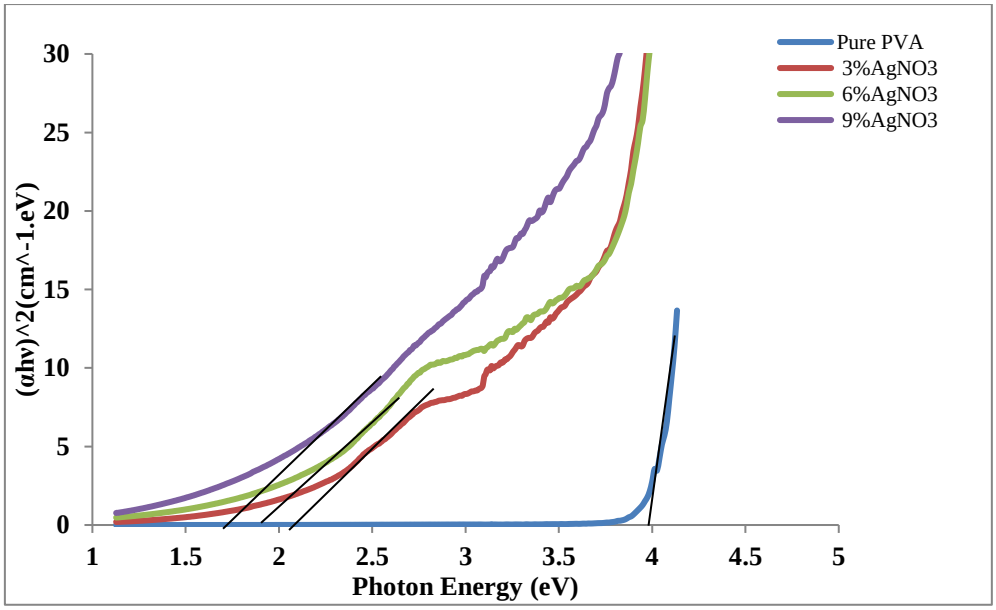

Fig.9. Energy gap as function of photon energy for pure and doped PVA.

The Ag doping is found to affect in strong manner on the optical energy gap of the polymer films, a decreases in the energy gap with increasing of Ag concentration maybe due to an increases in structural disorder of the polymer films and increases of the density of localized states in the band gap, which causes a shift optical energy gap to lower values of photon energy.

The absorption coefficient (α)and the extinction coefficient (K) can be involved by[20].

$$K=\frac{\alpha\lambda}{4\pi}\text{.....(11)}$$

The extinction coefficient (k) behaves just like the absorption coefficient(α) because they are joined by previous relation(7). From Fig.5 observe that the increases in absorption coefficient cause increasing in extinction coefficient values.

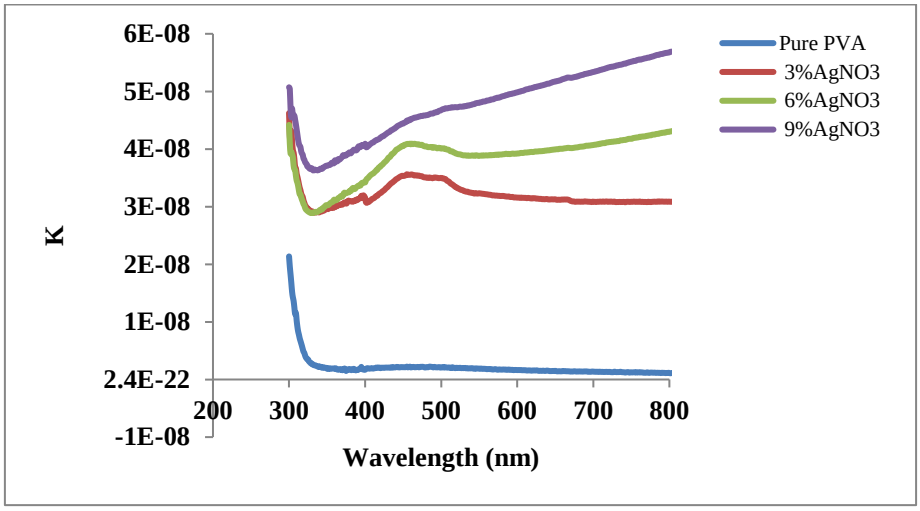

Fig.10. Extinction coefficient as function of wavelength for pure and doped PVA.

4. Conclusion

The optical constants of PVA as (absorption, transmission, refractive index, absorption coefficient, reflectance, extinction coefficient, and real & imaginary dielectric constant) were changing with increasing of concentrations of Ag nano particles. The energy gap of PVA decreases with increasing of concentrations of Ag nano particles also the transition was indirect.

Abstract. In the present study, the nanoparticle CuO solutions have been green synthesized with the use of the Aqueous copper chlorides and turmeric powder as a reducing agent in the deionized water as base fluid through the use of the traditional heating. This approach has produced large amounts of the Nano - products in a short duration of the reaction that takes several minutes, in addition to high quality materials with the innovative characteristics . A short review on some of the distinctive implementations and characteristics of the CuO Nano -structures will be presented as well.

Keywords: copper oxide, turmeric, nanoparticle and solutions

1. Introduction

The cupric oxide (CuO) , which has a narrow 1.2 eV band gap and various chemo physical characteristics, has been lately attractive in numerous areas like the energy conversion, opto-electronic devices, and catalyst in comparison to the bulk materials, the advanced characteristics of the CuO solution Nano - structures were shown; none-the-less, the fact that those materials can't be produced yet in the large scales is one of the obstacles towards the realization of the possible applications of that material. Thereby, the chemical approaches appear sufficient processes of synthesis, yielding large quantities as well as high quality and advanced material characteristics. And the Nano - fluids can be defined as a new fluids class, which has been engineered by Choi (1995) [1] the dispersing Nano sized materials (i.e. Nano - particles) in the base fluids. Which means that the Nano - fluids are Nano-scale colloidal suspensions that contain condensed nanomaterials . They are 2-phase systems with 1 phase (i.e. the solid phase) in another (i.e. liquid phase). The Nano – fluids were discovered to be possessing improved thermo physical characteristics like the viscosity , thermal conductivity , thermal diffusivity , and convective heat transfer coefficients, in comparison with the ones of the base fluids like the water or oil. It showed great potential applications in numerous areas like the transportation, micro - electronics, heating, manufacturing, and cooling. Numerous approaches were available to the synthesis of the CuO NPs with a variety of the morphologies. Those Nano - particles have massive benefits compared to the traditional materials, due to the fact that they have a large surface area. The formation of the well - dispersed Nano - particles is a difficult problem, due to the fact that they have the tendency of agglomerating with the time as well as the tendency of lowering the energy of the surface. Recently , the transition metal oxides nanostructures gained a massive interest from the material engineers and

scientists as a result of their various characteristics, in comparison to the corresponding bulk equivalents that are in turn providing potential implementations in a variety of the various technology areas. Preparations of the high quality Nano - structures of the defined, controllable morphology and size is a necessary condition, for the purpose of developing the Nano - devices or other variety of the applications for the sensing, catalyst, pharmacy [2–8] etc. The CuO, which has been classified to transition metal oxide group, is a p type, narrow band-gap semi - conductor. It is of a monoclinic structure and numerous interesting properties: super thermal conductivity, high stability, photovoltaic characteristics, and anti - microbial activities. Because of such exclusive characteristics, the CuO may be used in numerous technological fields, for instance, gas sensor [5, 7] active catalyst [2], magnetic recording media [9] highly efficient thermal conducting material [8], with highly sufficient selectivity, or solar cell applications [10]. Besides some shared metal oxide Nano - structure characteristics, like the ZnO, TiO_2, SnO_2, and WO_3. CuO Nano - structures have other distinctive magnetic and super hydrophobic [11] characteristics. In addition to that, those nanostructures have shown quite encouraging applications in the heterogeneous catalysis in complete hydrocarbons ' conversion to the CO2 , improvement of the thermal conductivity of the Nano - fluid, super -hydrophobic surfaces, nano-energetic materials, or anode materials for the lithium ion batteries (LIB). None – the less, this material hasn't gotten any attention from the scientists at the right level up to the past few years. In comparison to the other transition metal oxides like the TiO_2, ZnO , and Fe_2O_3 only a small number of the reports described the strategies of the synthesis that have been adopted for the CuO Nano - structures besides introducing their associated applications. In the present manuscript, we report on a green efficient method to prepare highly active copper oxide nanoparticles as a highly efficient catalyst.

2. Experimental details

Aqueous copper dichloride ($CuCl_2$) has been dissolved in 100 ml of the distilled water as a start. Then also dissolve turmeric powder in 100ml of distilled water and add the resulting 50% solution for 30 minutes in a sonic device at a temperature of 80 C. A clear green solution was obtained as in Fig. 1 Examination of the resulting solution by means of X-ray diffraction and finding the granular size using the Scherer equation [12].

From sherrer equation was calculated the average grain size (G_s for the thin films has been prepared, which include the XRD line width [11].

$$G_s = \frac{0.9\lambda}{\beta \cos(\theta)} \qquad (1)$$

Where, (λ) wave-length of x-ray, (θ) angle of diffraction, and (β) FWHM (the full – width at half - maximum) . The value of the strain (η) and the density of the dislocation (δ) value may be evaluated through the use of the relations in eq2 and 3: [12], as can be seen in Table1:

$$\eta = \frac{\beta \cos \theta}{4} \qquad (2)$$

$$\delta = \frac{1}{{G_s}^2} \qquad (3)$$

Fig.1. CuO freshly colloidal.

3. Results and Discussion

Fig. 2 displays XRD of copper oxide nanoparticles shown in Fig. 1, where the results showed an identical to the standard card (00-044-0706) , and using the equation (1) to find the particle size as shown in Table 1.

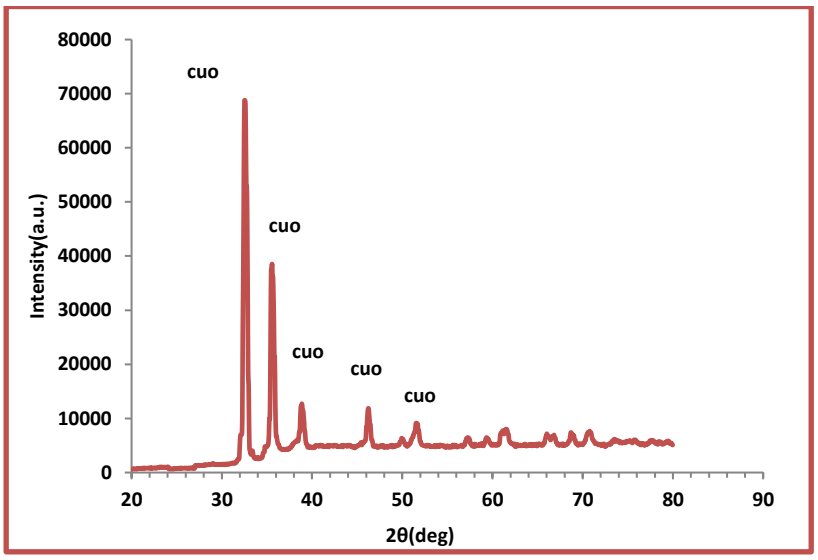

Fig. 2. XRD spectrum of CuO thin film.

Table 1. Parameters of CuO thin film

2θ(deg)	Gs (nm)	$\eta 10^4 lines^2 m^2$	$\delta 10^{14} lines m^2$
32.52	45.55	8.28	4.81
35.57	30.78	12.25	10.55
38.77	30.91	12.20	10.46
46.17	19.02	19.83	27.63
51.47	13.90	27.14	51.75

Fig.3 displays the 3D AFM photos and the chart division of copper oxide nanoparticles spread regularly on the surface. The figure showed that the average grain size shown in the figure is very close

to the X-ray diffraction results and We notice there is a homogeneity in the shape of the material with the appearance of some peaks that recorded the highest height at 222 (nm).

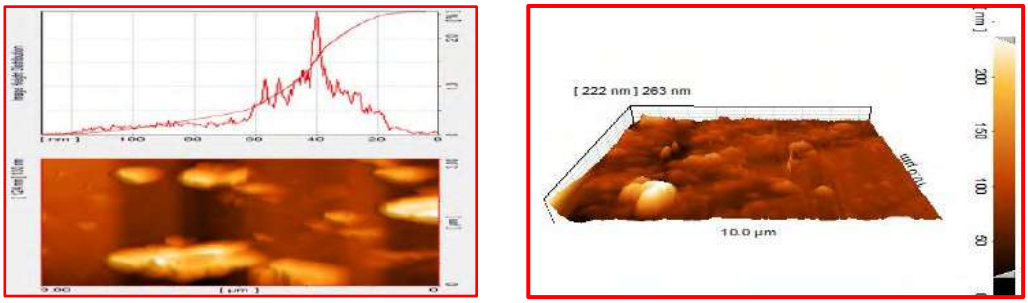

Fig. 3. 3D AFM image of CuO thin film.

Fig. 4 exposes the FTIR spectrum division of copper oxide nanoparticles spread that shows numerous significant peaks of absorption in the zone of 500- 3500 cm1 broad band of absorption has been designated to copper oxide, which assigned for Cu-O stretching vibration.

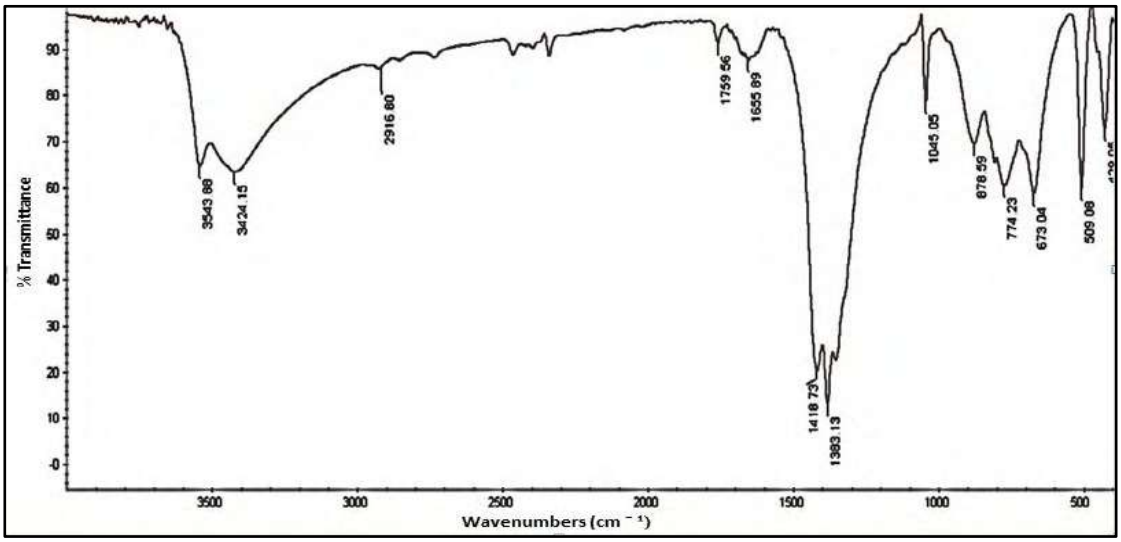

Fig.4. FTIR spectrum of CuO thin film.

Fig. 5 displays transmission as a wave-length function of the CuO which have been prepared with the use of the chemical process. Results have shown sufficient translucence characteristics at spectral range 200 nm – 1 ,100 nm and sharply increasing due to the absorbed particle size width. In addition to that, Fig. 5 the maximal transmittance value of 528 nm.

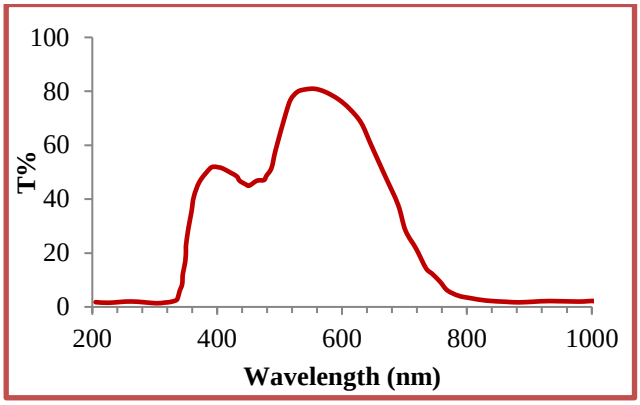

Fig.5. Optical transmittance of CuO thin film as a function of the wavelength

The optical energy gap of $AgInSe_2$ has been computed by the equation [13]

$$\alpha h\nu = B(h\nu - Eg)^n \qquad (4)$$

Where B represents a constant, ν represents the frequency of the transition and r exponent characterized the transitions of nature. r = 1/2 & 3/2 agreed to transitions of direct allowed and transition direct forbidden and r = 2 & 3 agreed to transition of the indirect allowed and transition of the indirect forbidden, respectively. Fig. 6 shows the linear plot that has been indicated as a direct band gap film nature .The line to the energy of the photon axis gives band gap. There have been two energy gaps shown in Fig. 6. The optical energy gap values for CuO are 1.8eV and 2.5e which results from increasing the localized states' density in Eg.

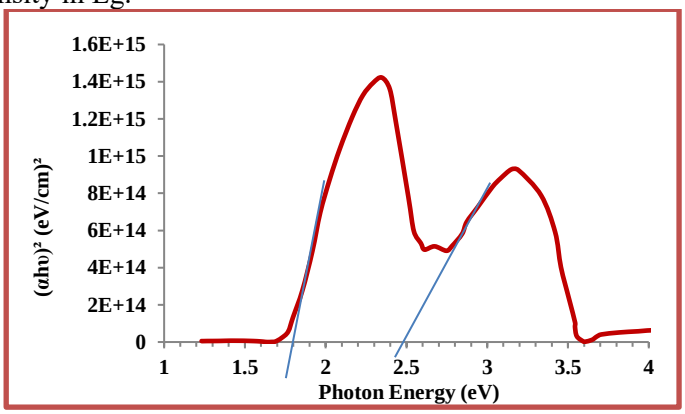

Fig. 6. $(\alpha h\nu)^2$ photon energy of CuO thin film**.**

The images of the scanning electron microscopy have been obtained for the CuO Nano - particles. Fig. 7 illustrates Cuo NP SEM image , indicating that the particle morphology is in an unspecified form and shows the agglomerates for the particles , and Fig. 7 shows SEM image and EDX , respectively

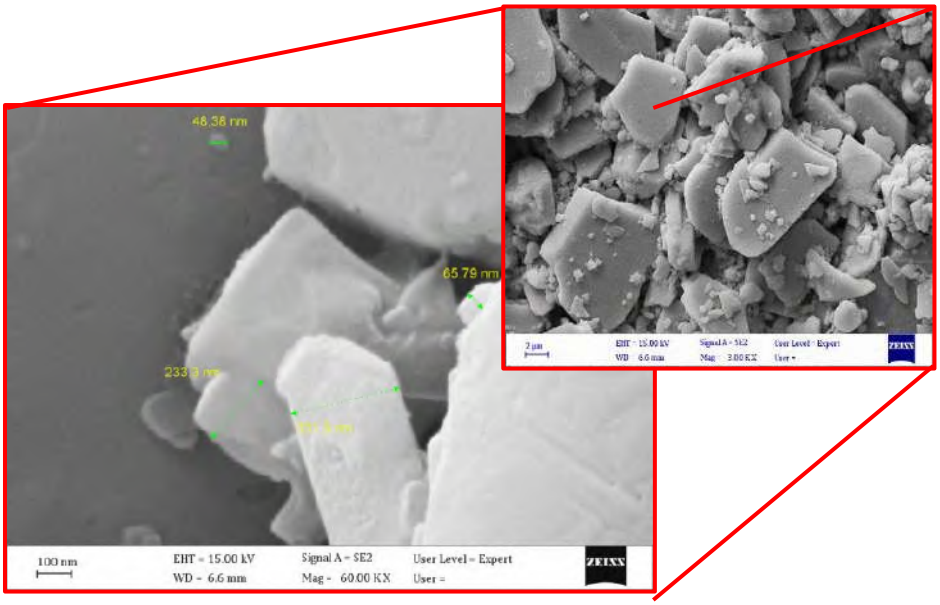

Fig. 7. SEM image of CuO thin film.

The EDS spectra of CuO thin film samples (Fig. 8) clearly demonstrate the presence of only peaks corresponding to Cu and O elements. The observed atomic ratio of 2 : 1 between Cu and O elements suggests the presence of CuO in these films. But, the XRD results suggested that the films predominantly contain CuO. There were no peaks related to the elements other than Cu and O in the EDS spectra, which revealed the formation of phase pure CuO in the thin films prepared through sputtering The new percentage after removing the carbon rate (cu = 64.12 , O = 35.73).

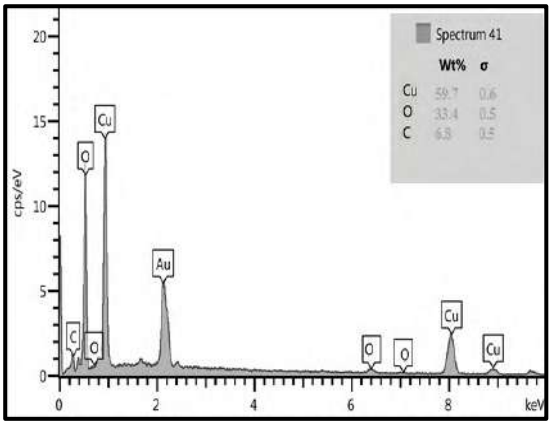

Fig. 8. EDS spectra of CuO thin films.

4. Conclusions

CuO the dissolved nano fluid was synthesized with the use of the chemical approach, utilizing the copper dichloride as precursor, and the average nano-particle size has been discovered 45nm, which is computed with the use of the De-Scherrer equation. The results were also compared mediated by SEM and EDX.The energy gap was calculated for the prepared solution, as two energy holes were obtained at high and low energies

Abstract. Expanded Polystyrene (EPS) solutions with a percentage of (30 wt. %) were prepared followed by the fabrication of micro-fibers membranes by electrospinning technique. To study the voltage's effect of electrospinning device on EPS micro-fibers membranes, different voltages (10, 12, 15, 18, 24, and 30) KV were experimented. The characterization of the electro-spun membranes were made by Fourier transform infrared spectroscopy (FTIR) and the scanning electron microscopy (SEM) for morphological and thickness analysis. The results showed that although electro-spun EPS membranes prepared by 30 KV, they had the minimum membranes thickness and the highest average fiber diameter. As it is cleared by SEM images, increasing the electro-spinning voltage leads to increasing the average fiber diameter membranes. With increasing the electros-pinning voltage, the fibers prefer to deposit on each and result in decreasing the distance between the collector and the needle, hence higher average fiber diameter produced. The thickness of the electro-spun membranes decreases with the electro-spinning voltage as a result of the higher repulsion between the electro-spun fibers which reduce the deposition of these fibers on the collector.

Keywords: EPS, Electro-spinning, average fibre diameter, Thickness test.

1. Introduction

Electrospinning technique is a multi-sided technique has the ability to produce nano and micro polymeric fibers [1]. High aspect ratio as well as large surface area is important characteristics that made the electro-spun fibers attracted a considerable attention due to their special characteristics and potential applications in electrochemical devices [2]. This technique has attracted large attention in recent years due to the easy production of fibers from natural either or synthetic polymers [3]. Every soluble polymer owns enough high molecular weight is suitable to be electro-spun. The electro-spinning device consists of the following parts: (i) a high voltage power supply, (ii) nozzle, and (iii) grounded collector as shown in figure (1) [4].
Due to applying high voltage, the polymeric solution (presents at the tip of the syringe needle) will be charged and this will lead to the formation of a repulsive force. At the same time, the Taylor cone (which is a conical structure) will be formed at the tip of the syringe needle [1]. At a critical voltage, the repulsive forces could be able to dominate the surface tension of the polymeric solution and consequently, a jet blows up from Taylor cone. The jet is accelerated and goes along the distance between the syringe needle tip and the collector, and divided into a large number of filaments. Along

with the distance, the solvent will be evaporated and the fibers form on the surface of the collector [5]. To fabricate fine fibers, adjusting of some special solution-, environment- and operation- parameters is required. The presence of beads is also considered as a common problem. The higher concentration of the solution is the most preferable suggestion to solve this problem because it leads to minimizing the number of beads. At the same time, the higher concentration will lead to a larger diameter of the fiber [6].

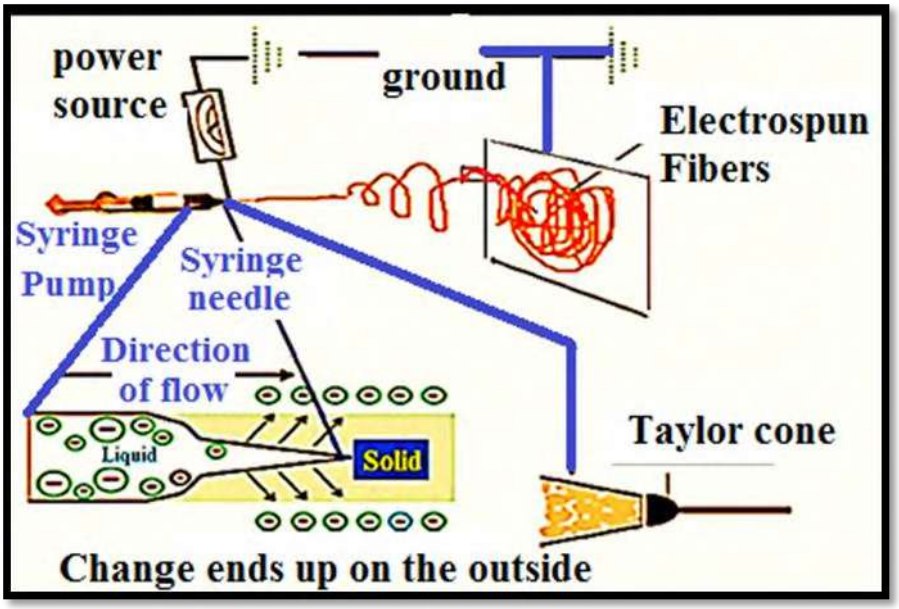

Figure 1. Basic set up and phenomenon of electrospinning [4].

The selection of the solvent used in electrospinning technique is one of the critical factors for the smooth and beadles' electro-spun nanofiber formation. The chosen solvent must lead to a complete soluble polymer added to moderate boiling point. The boiling point gives an important impression of the solvent's volatility. Generally, volatile solvents are preferred due to their high evaporation rates [7]. Fast evaporation of the solvents should be avoided because low boiling points causes drying the jet and blocking the needle tip, hence hindering the electro-spinning process. Similar to the fast evaporation solvents, low volatile solvents are avoided also because high boiling points prevent the drying during electro-spinning, whereby electro-spun fibers need to reach the collector [8].
The main electro-spinning technique parameters are the flow rate, the distance between the capillary and collector and applied voltage. At low flow rate, there is enough time for the solution to polarize. While, high flow rate leads to beads formation along the fibers, and it causes thick diameter. This is due to short drying periods whereby electro-spun fibers needed to reach the collector [9]. The distance between the tip of the capillary and the grounded plate directly affected the morphology of electro-spun nanofibers. If this distance increased, more uniform and beadles' electro-spun fibers may be obtained. Higher distance provides sufficient time and results in finer fibers with more uniform diameter distribution [10]. According to the voltage of electrospinning device, there are two different effects notified by the electro-spinning researchers. The first effect of electro-spinning voltage is associated with the vast majority of researchers when the electro-spinning voltage is increased, the volume of the drops at the tip decreased resulting in receding the Taylor cone. The jet originates from the liquid surface within the tip, and more beading is seen. If the applied voltage increased, the diameter of the fibers reduced. In the case of low applied voltages, fibers with no beads are produced (if the electric field is quite enough to overcome the surface tension) [11, 12].

While, some researchers are notified and adopted different and opposite effect depends on the fact that when the applied voltage is high, the coulombic forces were much greater than the viscoelastic forces. This would cause not only the breakage of an over-stretched charged jet during its path to the target but also the charged jet travelled to the grounded target in a shorter time. Therefore, the solvent has less time to evaporate, and this leads to bigger but irregular fiber diameters [13]. Marilena V. et al explained that there is a critical voltage. If the applied voltage during electrospinning is less than a critical voltage, increasing electrospinning voltage leads to decrease the diameters. While, when the applied voltage is higher than the critical value, the fiber diameters are increased, Taylor cone size and the drop's size at the needle tip are decreased and the jet velocity is decreased [14]. Electro-spun fibers in (nano or micro) scale have versatile spread applications such as solar cells, air filtration membranes, gas and chemical sensors, piezoelectric sensors, fuel cells, energy storage and ion exchange membranes [15], self-cleaning membranes, anti-corrosion, responsive smart materials, anti-icing, micro- and nano- electromechanical systems [16].
The aim of this research depends on utilizing different electrospinning voltages (10, 12, 15, 18, 24, and 30) KV in order to study their effects on the thickness of the electro-spun membranes and the topographical and morphological properties especially on fiber diameters and the general histogram of electro-spun fibers.

2. Experimental part (Preparation of PS electro-spun membranes)

Expanded polystyrene solutions and membranes were prepared by same method mentioned in our previous work [17, 18]. Expanded Polystyrene solutions of 30 wt. % were prepared by dissolving expanded polystyrene in (N, N- dimethylformamide DMF) at 100 °C with a continuous stirring for (20-25) minutes to ensure complete dissolution and homogeneous solution. Fabrication of PS electro-spun membranes was performed by electrospinning technique. The Polymer solution was injected in a (10 ml) syringe pump at fixed electro-spinning parameters. These parameters include the flow rate was 1.0 ml/h, the time of the electro-spinning for each membrane was 1.5 h and the distance between the syringe needle and the collector was 12 cm. Different electrospinning voltages (10, 12, 15, 18, 24, and 30) KV were experimented to study the effect of the voltage on the electro-spun membranes. Then, the obtained electro-spun membranes were removed from the collector, and the membranes were cut into small pieces (2 x 2) cm for subsequent characterizations.

3. Characterization of sulfonated electrospun membranes(SPS):

3.1. Fourier transform infrared spectroscopy (FTIR)

It is a non-destructive technique used for yielding information about the chemical bonds which in turn lead to the chemical composition of present membranes. FT-IR spectrum is recorded for the absorption of electromagnetic radiation of the sample in the range of the wave numbers from (4000 - 400) cm^{-1} [19]. FTIR was used to characterize the appearance of the chemical bands. The basic peaks related to the chemical structure of PS $(C_8H_8)n$. FTIR can qualitatively identify the structure of unknown materials and the quantitative measurement of the components in a complex mixture [20].

3.2. Scanning electron microscopy (SEM).

The scanning electron microscope (SEM) is considered as one of the most versatile instruments for the examination and analysis of the microstructure characteristics of solid objects. Scanning electron microscopy (SEM) gives information about topography and morphology of the electro-spun fibers [21].

4. Results and discussion:

4.1. Fourier transforms infrared spectroscopy (FTIR):

FTIR of (30 wt.%) expanded polystyrene membrane appeared clearly in fig.(2). generally, based on the wavenumber, there are three main regions. Region (1) shows that the bands at (400-900) cm^{-1} associated with (out-of-plane) C-H bend vibrations of aromatic rings. Region (2) defines the bands at (900-2000) cm^{-1} associated with the vibration of substituted benzene rings and in-plane C-H deformations. Region (3) represents the bands at (2800-3200) cm^{-1}. These bands are related to aliphatic and aromatic C-H stretching [23].

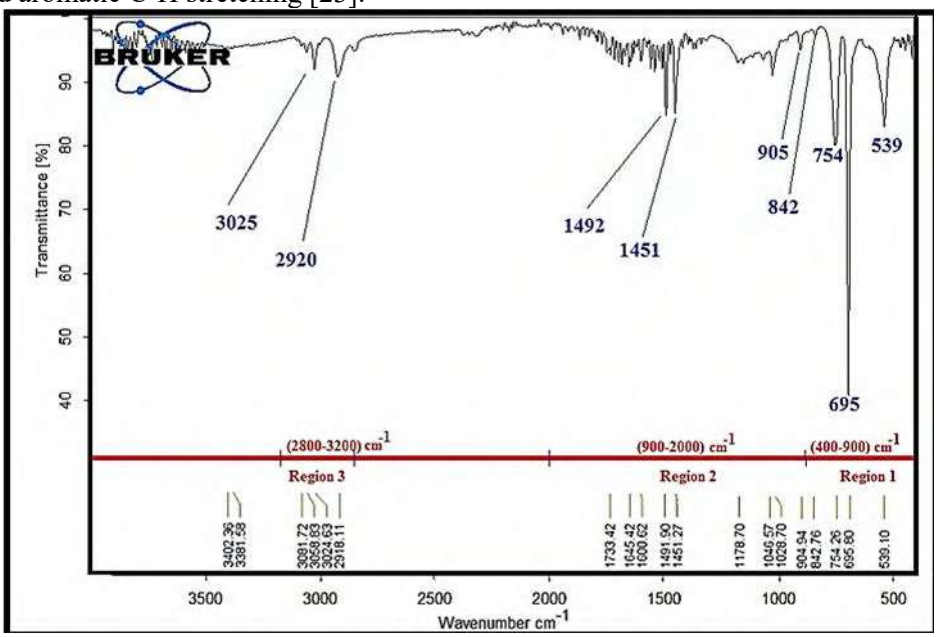

Figure 2. FTIR spectra for electrospun expanded polystyrene

The principle peaks associated with the chemical bonds of the expanded polystyrene are the peak appeared at a wave number of 695 cm^{-1} which is related to bending (=C-H) out of the plane, the peaks at (754 , 842, 905) cm^{-1} which related to substitution of the benzene ring, while the peaks at (1451 and 1492) cm^{-1} are associated with aromatic (C=C) stretching .The peak appeared at 2920 cm^{-1} are belongs to stretching vibrations of ($-CH_2$), the peak at 3025 cm^{-1} is associated with aromatic and aliphatic (C-H) stretching, and the peaks at (1028, 1069, 1154, 1181) cm^{-1} are related to in-plane C-H bending of the phenyl ring [24,25, 26]. The (in-plane C–H bending) of the phenyl ring is usually weak in most aromatic compounds, and it is observed at (1028, 1069, 1154, 1181) cm^{-1}[27]. The peaks at 3082, 3060 and 3026 cm^{-1} correspond to the aromatic C-H stretching vibrations, while the bands at 2923 and 2848 cm^{-1} come, respectively, from the asymmetric and symmetric stretching vibrations of methylene groups ($-CH_2$)[23].

4.2. Scanning electron microscopy (SEM).

From figs.(3, 4, 5, 6, 7, 8), the higher the voltage during electrospinning, the greater the average fiber diameter. This result is completely different with a very large number of researches specialized in the field of electro-spinning, which confirm the decrease in the fiber's diameters if the applied voltage increases [28, 29]. To explain the reason for increasing the fiber's diameter the applied voltage, it is important to notice that DMF is a solvent with high dielectric constant properties. The dielectric constant is a measure of how a material placed in an electric field can concentrate effectively the flux the electrostatic lines. So, with high dielectric properties, the fiber's diameter decreased, and the density of the surface charge on the jet largely dispersed resulting in the production of fibers with uniform morphologies and less diameter along with lower bead formation [30]. It is important to mention a special case during polystyrene electro-spinning. Only at the first few seconds of the electrospinning process, the fibers are gathered on the collector and form a very thin film. After few

seconds, the formation of the thin film on the collector is stopped, and the fibers vertically gathered towards the needle. During the path of the fiber to the collector (which is usually a conductive material), the fibers were cut and did not continually extended. The fibers stop gathering on the collector and start gathering on each other.

This complex is attributed to the special properties of (PS/DMF) solution where the electro-spun fibers prefer the surface of each other due to the conductive surfaces and shorter distances. This case was somewhat little happening at small voltages, but increases with increasing the applied voltage during electro-spinning. It is important to mention that the fibers were cut into small lengths before reaching the collector. This reduces the distance between the needle and the collector that causes the formation of larger average fiber diameters. The fibers gathered on the collector after few seconds of starting the electro-spinning process, and the fibers have lower diameters due to large distance, then the diameters gradually increased. In other words, the interpretation of increasing the fiber diameter is due to the segmentation of electro-spun fibers when the distance between the collector and the needle decrease in such away making the diameter becoming higher. This explanation was in good agreement with Siqi Huan et al [13].

Table (1) clarifies the relationship between increasing the average fiber's diameter with increasing the electro-spinning voltage. It is important to mention that there is not any membrane obtained when the electro-spinning voltage was 10 KV since it is very small voltage to form the electro-spun fibers. Also, when the electrospinning voltage was 30 KV, it is difficult to perform the electro-spun due to the high repulsion forces between the fibers themselves.

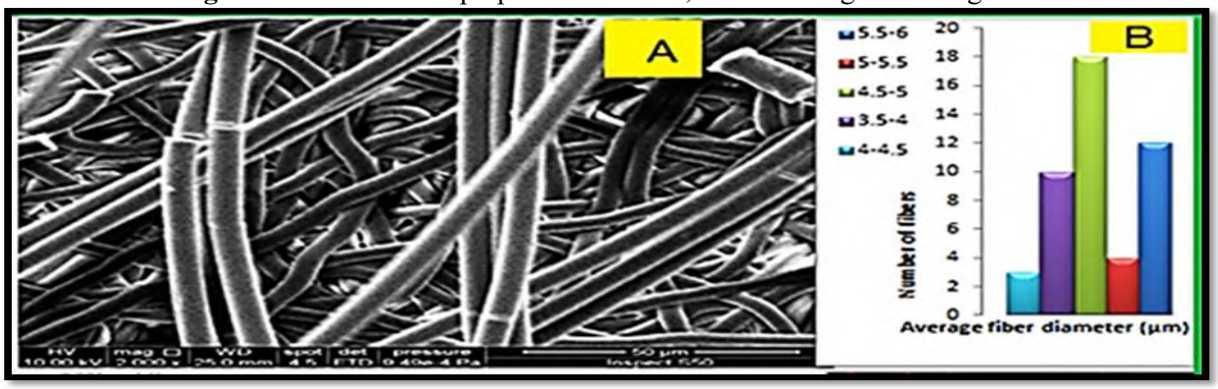

Figure 7. 30 wt.% EPS prepared at 30 KV , A:SEM image B:Histogram

Table 1. Electro-spinning voltages with average fiber diameter of EPS membranes

Electrospinning Voltages (KV)	Average Fiber Diameter (μm)
10	There is no electrospun membrane at this voltage
12	1.25 ± 0.25
15	1.75 ± 0.25
18	2.25 ± 0.25
24	4.25 ± 0.25
30	4.75 ± 0.25

4.3. Thickness test

Table (2) illustrates decreasing the membranes thickness with increasing the voltage of electro-spinning device. With constant conditions of electro-spinning process, the thickness of the electro-spun membranes was decreased with increasing the applied voltage during the electro-spinning. Decreasing the membranes thicknesses may be related to increasing the electrical conductivity of the polymeric solution with increasing the applied voltage. Lower deposition rate of electro-spun fibers on the collector was attributed to polymeric fibers repulsion in higher conductive solutions that leads to spread over large areas and finally the produced film will be thinner. Our results agreed with [31, 32, 33]. Indeed, any enhancement for the electrical conductivity for polymeric solutions results in higher charge density on the surface of the charged jet, and this encourages or promotes the solution jet stretching as a consequence of higher level of charges.

It is important to mention that the dielectric constant of the electro-spinning solvents plays a very important role in limiting the amount of available free charges in electro-spinning solution. By using low dielectric constant solvent such as chloroform, lower amount of charge density will result and therefore the available charge on the jet surface reduces and weakens the electrostatic repulsive force (34, 35, 36).

In contrast, our results depend on the use of DMF solvent with high dielectric constant that causes higher charge density on the jet surface and encourages the electrostatic repulsive forces. Therefore, with increasing the electro-spinning voltages along with the effect of high dielectric constant of DMF, higher repulsive forces and lower fibers deposition rate was obtained.

Table 2. Relationship between thickness of electrospun membranes and electrospinning voltage

Electrospinning Voltages (KV)	Thickness of produced electrospun membranes (Cm)
10	There is no electrospun membrane at this voltage
12	0.1379
15	0.113
18	0.09889
24	0.08167
30	0.0511

5. Conclusions:

The experimental results of this paper indicate the following conclusions for EPS electro-spun membranes.

1. The average fiber's diameter of the electro-spun membranes increases with increasing the electro-spinning voltage.
2. There is no electro-spun membrane produced with 10 KV
3. The thickness of the electro-spun membranes decreases with increasing the electro-spinning voltage and becomes difficult to produce electro-spun membranes.

Abstract. The optical design process includes a myriad of tasks that the designer must be performed and consider in the process of optimizing the performance of the optical system. In this article, a design based on four groups of materials for a multilayer dielectric cold mirror: V_2O_5 \MgF_2, Sic\ MgF_2, TiO_2\ MgF_2, and Al As\ MgF_2 where MgF_2 represents low refractive index and other material in each group represent high refractive index. A cold mirrors are a special dielectric mirrors that reflects the entire visible wavelength band, while the transmitting infrared wavelength band. These systems of mirrors are constructed for an event angle from 0 ° to 45 ° and are modeled with interference filters-like multi thin layer dielectric coatings. The results of our work designed shows the mirror based on Al As /MgF_2 is the most promising design for cold mirror with the highest reflection in the visible region and the highest Transition in the IR region. In the spectrum range of 400-800 nanometers, the average transmission is much less than 1 %, while the average transmission is 95 percent in the wave band 800-2500 nanometer.

Key words: Multilayers Coatings, Cold mirror, Characteristic matrix.

1. Introduction

In optical manufactured devices, optical coatings are founded to be an important requirement. Through changing the direction of propagation, spectrum, the magnitude, phase or polarization, can be used to match the optical media and regulating the light radiation [1]. These optical coatings consisting of one or more of thin layers of metal or insulating materials, [2,3] has a number of important applications in many branches of science and technology [4]. Thin coatings have been used to improve a glass's color and efficiency of energy and as reflective coatings for a mirror [5]. Thin-layer optics and many devices such as stop-band filters are a well-advanced technology. The use of multi-layer insulating thin films has been successfully developed with band pass filters, reflectors and polarizer's [6]. Due to their availability, proven reliability and long-term stability, multi-layer dielectric filters are commonly accepted in optical networks. The filters can be made to have excellent wavelength stability, making them ideal filters for passive components. In the fact, dielectric filters are sometimes used to stabilize the wavelength of active ingredients [7]. The optical components consist of multi-layers of High and Low refractive indices material of specific thicknesses, consciousness of the refractive indices and absorption. Multi-layer dielectric filters are based on the concept of multiple reflections that occur between high and low index material interfaces [8].

A dielectric mirror, also referred as a Bragg mirror, is a type of mirror consisting of several thin layers of dielectric material usually deposited on a glass or optical material substrate. This type of a mirror consists of a several thin layers of an insulating material, which is coated on a glass substrate. The behavior of such a mirror depends on the constructive interference between the light reflected from the individual layers. The dielectric mirror can have very high reflection, to better than 99.99%. The dependence of the wavelength of reflection is used to achieve various special types of mirrors, such as a hot mirror which reflects longer wavelengths and is transparent at shorter wavelengths [9]. To reflect a visible light spectrum and transmitted the Infra-Red (IR) wavelengths containing the thermal energy. Cold mirrors are dialectically coated on a glass substrate. Cold mirrors are used to control the thermal energy entering temperature sensitive systems, also have an excellent alternative for transmitting the near infra-red spectrum. Cold mirrors have a sharp cut off between IR and visible light because they have a dielectric coating that can be controlled it. Its apposite for hot mirror can be defined as a narrow band multilayer that reflects targeted wavelengths, and transmits visible light. It is a specialized dielectric mirror, a dichroic filter that reflects the entire visible light spectrum while very efficiently transmitting infrared wavelengths [10]. This mirror is based on the concept of multiple reflections between high and low material interfaces [10, 11]. Cold mirrors are used to control thermal energy entering temperature sensitive systems and are also an excellent alternative for transmitting the infra-red spectrum. There are many practical uses for cold mirrors, such as copying machines, medical instruments , fiber optic lighting and are often used with tungsten lamps which are the source in a projector or lighting system [6]. Finally cold mirrors can be employed as dichroic beam splitters with laser systems to reflect visible light wavelengths while transmitting infrared. Cold mirrors can be designed for an incidence angle ranging between zero and 45° degrees, and are constructed with multi-layer dielectric coatings, in a manner similar to interference filters [12]. In this paper, five groups of materials of: V_2O_5 \ MgF_2, Sic\ MgF_2, TiO_2\$MgF_2andAlAs$\$MgF_2$ optical coating instead in one stack is utilized to design cold mirrors has a high reflectance at 550 nm and a low reflectance in IR waveband at 1100 nm.

2. Simulation Tool

To design interference optical filters open software program "open filter" has been used. This software calculates optical properties of filters and the state of polarization of electromagnetic (EM) radiation that can be expressed by the characteristic matrix of the thin film method for calculating the transmission properties of filters. This software is also utilized to design several multilayer filters [13]. In this program, optimization methods such as injection synthesis is possible (adding an extra layer to give selective transmission) [1 4].

3. Cold mirror design

The behavior of the total multilayer structure is calculated according to the characteristics of the individual layers in the stack when optical filters designing [6]. In this article, colds mirrors designing in the spectrum of 400-2500 nanometer, at the wavelength design 500 nm, by use Open filter software to transmits the spectrum of interest selectively also to reflects the unwanted spectrum in the visible spectrum. It used four groups of materials: V_2O_5 \$MgF_2$, SiC\ MgF_2, TiO_2\$MgF_2$, and $AlAs$\$MgF_2$ where MgF_2represent low refractive index (1.38) and other material in each group represent a high refractive indexV_2O_5(2.3),SiC(2.69), TiO_2 (2.88) and AlAs(3.38)[15].To examine the transmission and reflection of light from layers based on the thickness and form of materials, the open filter uses the transfer matrix method. Using the needle synthesis process, to optimize the transmission of design needed at wavelengths (adding small dense layers called needle and transmission analysis prior to achieving the best results [6].

4. Theoretical approach

A classical optical filter consists of a number of thin layers of *dj* thickness and *Nj* refractive indices between the incidence and exit media of *Ninc* and *Nex* refractive indices, respectively. By using characteristic matrix method to measure filter optical properties, and discussed in depth in most optical coatings textbook, such as Macleod [16], the ith layer is represented by:

$$\mathrm{M}=\begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix} = \prod_{j=q}^{j} M_j \quad \text{.....(1)}$$

Where *q* is the multi -layer, and the product is taken in reverse order since the matrices of upper layers must be multiplied on the left.

$$\begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix} = \begin{pmatrix} \cos\delta_H & isin\,\delta_H/\eta_H \\ i\eta_H sin\delta_H & cos\delta_H \end{pmatrix} \begin{pmatrix} cos\eta_L & isinn\eta_L \\ i\eta_L sinn\eta_L & cos\eta_L \end{pmatrix} \text{.....(2)}$$

Where δ_H and δ_L is phase thicknesses of the High indices, η_H, and Low indices, η_L materials respectively. It can be expressed as:

$$(\delta_j = 2\pi N_j d_j cos\,\vartheta_j/\lambda_\varrho \ldots\ldots(3)$$

Where *j* =*H* or *L*and ϑ_j is the angles of refraction in the j[th]layer. The refractive index is given by an effective index:

$\eta_j = \mathrm{N_j}\ \cos\theta_j \ldots\ldots\ldots\ldots(4)$S polarization state

$\eta_J = N_j/\cos\theta_j \ldots\ldots\ldots(5)$P polarization state

η_j is the effective index and θ is the angle of incidence.
The amplitude transmission coefficient of the thin layers is:

$$t = \frac{2\eta_{inc}}{\eta_{inc}m_{11} + \eta_{exi}m_{22} + \eta_{inc}\eta_{exi}m_{12} + m_{21}} \ldots\ldots\ldots(6)$$

$$T = \frac{R_e N_{exi}}{R_e N_{inc}} tt^*$$

$$T = \frac{R_e N_{exi}}{R_e N_{inc}} |tt|^2 \ldots\ldots(7)$$

Where Re is the real part, * denotes the complex conjugate and T optical transmittance.

5. Results and Discussion

In this research, the stack of design Air [1.15(0.35H L 0.5H)^5 2L] glass of cold mirror where H represents the high quarter wave of optical thickness and L represent the low quarter wave of optical thickness with $\lambda_{\circ}$=500 nm. Cold mirror was obtained by using four groups of materials (V_2O_5 \ MgF_2, SiC\ MgF_2, TiO_2\ MgF_2andAlAs\ MgF_2) with a number of layers are12 layer only. The best result as shown in Figure 1 using AlAs\ $MgF_2$with transmission is less than 0.01, so that it has been found at *the high variance in refractive indexes i.e., high to low refractive index ratio*, sharp cut off between IR and visible light can be achieved and obtained a better optical performance of cold mirror. In all the designs for dielectrics stack of cold mirror, It's found that optical performance of the AlAs\ MgF_2 formation shows better results with a desired spectral purity, side part pulses (pass-band oscillations) is low in compared to other groups. Also these mirror formation have a smooth transmitted in the spectral range from 399.5 -786.3 nm and above 800 nm 100% 96.5%, respectively as shown in Figure 1. It can be seen the summary of results for the optical performance at normal incidence angle of multilayers with different groups shown in Table 1.

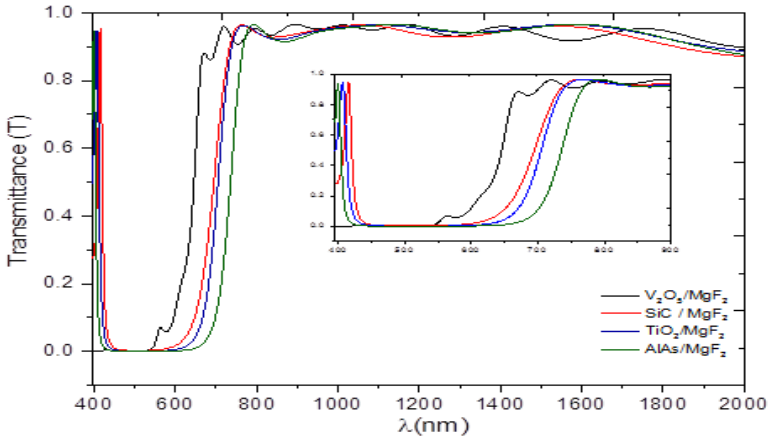

Figure 1. The Optical performance cold mirror at normal incidence using stacks Air [1.15(0.35H L 0.5H) ^5 2L] glass.

Table 1. Optical performance of Multilayers for different groups.

Multilayers with different Index ratio(n_H/n_L)	Optical performance at normal incidence angle		
	R% over the Vis-spectral region at 500nm	spectral range (nm)	T% over the NIR-spectral region at 1100nm
V_2O_5(2.3) /MgF_2(1.38)	100	300-668	95.8
SiC(2.69) /MgF_2(1.38)	100	414-758	93.3
TiO_2(2.88) /MgF_2(1.38)	100	406-758.077	94.2
AlAs(3.38) /MgF_2(1.38)	100	399.5-786.3	96.58

The effect of angle of incident was studied on the optical efficiency of the cold mirror. Where the transmittance has been calculated according to the effects of the incident angles for the materials using

equations (7), as illustrated in Figure 2. It has been noticed weak effect showing of the optical performance of the cold mirror at the angle of incident of un-polarized light is equal to (θ = 0°, 20°, 25°, 30°).

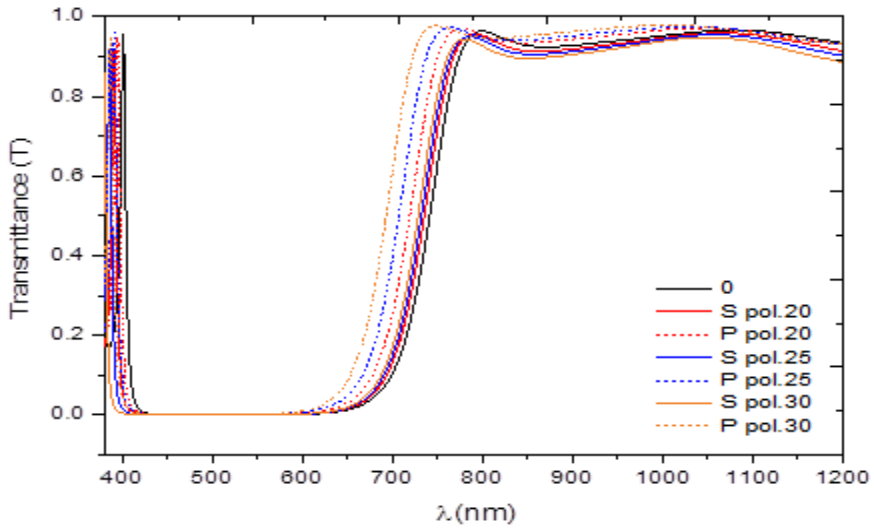

Figure 2. The Optical performance cold mirror at incidence angle of 0°, 20°, 25°, 30°.

When the incident angle of un-polarized light increased (θ =35°, 40° and 45°) it has been noticed the optical performance of these mirrors becomes better as shown in Figure 3. The angles of incidences are increased, a central spectrum for the cold mirror design changes to the lower wavelengths. At the incident angle of the light increased from 0° to 45°transmitted range change from 790 to 662nm .Then it's possible to obtaining a good optical performance of the cold mirror for different angles and is not limited to the angle of incidence of 45 and zero. For all designs, the optical transmittance is determined by angle of incidence. It can be seen the summary of the results for the optical performance at oblique incident angle of un-polarized light shown in Table 2.

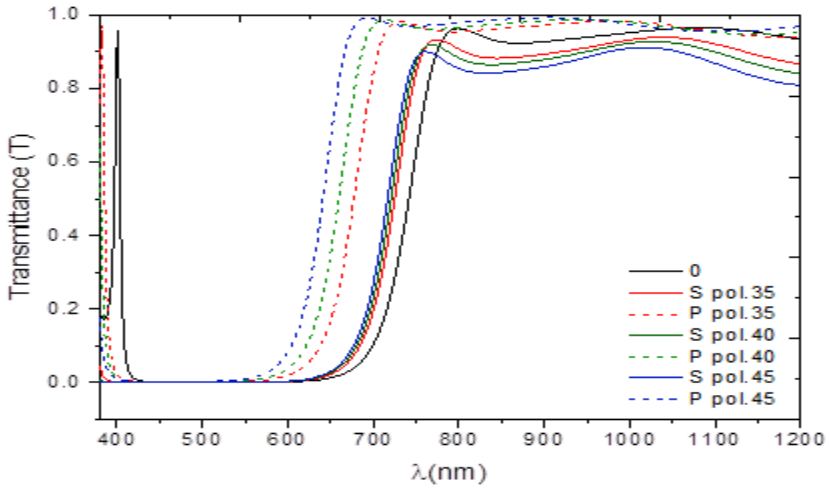

Figure 3. The optical performance cold mirror at incidence angle of 0°, 35°, 40°, 45°.

Table2. Optical performance for oblique incident angle of un-polarized light.

Angle of incidence(°)	Transmittance%			
	S Pol.	Waveband (nm)	P Pol.	Waveband(nm)
20	0-95.5	(391.8-790.01)	0-96.8	(395-770.2)
25	0-95	(385.1-782.3)	0-97.2	(391-758.01)
30	0-94.4	(380.2-775.4)	0-98.2	(386-751.4)
35	0-93	(375-766.56)	0-98.8	(382-740.2)
40	0-92.1	(372.4-764.3)	0-99	(377-725.1)
45	0-89.5	(357-762.86)	0-99.8	(372-694.1)

6. Conclusions

Here optical designs of a multilayer cold mirror have been carried out to calculate the optical performance of optimum designing of four groups of materials (V_2O_5 \ MgF_2, SiC\ MgF_2, TiO_2\ MgF_2 and AlAs\ MgF_2) with number of layers 12 layer. The stack of AlAs\ MgF_2optical coating is optimal design with a desirable spectral purity and small ripples in the transmittance band in compared to other groups and reflects greater than 96.5%, in the visible waveband 399.5-786.3 nm and transmit highly above 800nm. Moreover, the relative phase change between s- and p-polarized and a transmittance band by means of adjusting reflectance and interference orders can be adjusted by varying the index ratio .Finally, it can achieve optimum optical efficiency of a cold mirror for different angles and is not limited to the incidence angles of 45 and zero.

Abstract. In this study, titanium dioxide (TiO_2) pure and doped prepared with tungsten at 5, 7 and 9 %, using pulse laser ablation method. The influence of different doping ratio of tungsten investigated on the structural properties and optical properties. X-ray measurement showed that the crystal size was increased by increasing doped concentration. From UV- visible data it has been found that the tungsten doping leads to a change in the optical band gap. ApplicationTiO_2 as photo catalyst was studied on the degradation of methylene blue (MB) dye under UV illumination, which revealed the highest degradation of MB at a ratio of 9%.

Keywords: Titanium dioxide, tungsten oxide, PLA, Photo- catalyst.

1. Introduction

Titanium dioxide (TiO_2) is abundant in nature, safe with high optical transparency and largeenergy band gap [1]. Nanoparticles TiO_2 are chemically and biologically stable and are of low-cost, so employed as photocatalysts [2]. Photocatalytic technology has shown great potential as aninexpensive, environmentally-friendly, and sustainable technology; and it has been highly research [3]. ZnO, WO_3, and TiO_2 are semiconductors. They also can be used as a photocatalyst and non-toxic materials for the human beings for that used as antibacterial, plants andanimals [4]. The TiO_2 is the optimum active photocatalyst under photon energy of 300 nm< l <390 nm and it remains stable after the repeated catalytic cycles, whereas Cds or GaP are degraded along to produce toxic products [5].

Pulsed laser ablationin liquid (PLAL) can produce the extreme conditions and lead to the formation of the novel nanostructures and for that, it has attracted large interest [6]. Also, the simple experimental set-up and one-step fabrication process make laser ablation in liquid (LAL) an alternative choice to the traditional wet-chemical methods [7]. Tungsten oxide nanostructures have a wide variety of applications [8]. Tungsten oxide is a semiconductor and it has indirect wide band gap of 2.2 to 2.8 eV [9]. TiO_2 photocatalyst, which produces free radicals on its surfaces by adequate light activation, has cometo utilization such as self-cleaning [10]. The degradation of the dye depends on thetime of illumination, and the absorption intensity gradually reduced with the increase of illumination time [11-12].

2. Experimental part

2.1 preparing of samples

Target of titanium plat and tungsten plate using to prepare nanoparticle by pulse laser ablation method. Nd:YAG laser was used with wavelength (532nm), frequency (1 Hz) ,voltage (900 volt) and (2000 pulse),(5 ml) distilled water (DW) has been putted in container and (Ti) target immersed in DW to control the nanoparticle and to reduce thetarget heat. Same conditions using with both targets (Ti) and (W), after preparing nanoparticle as collide in DW the solution deposited as thin films by drop casting method. Tungsten using as impurities, the doping concentrations were 5%, 7% and 9% calculated volumetrically. Titanium and tungsten solutions were mixed by usingmagnetic stirrer for 30 mints. After that it was depositedusingthe drop casting method on cleaning glass substrates (2x2 cm^2) at temperature about (90 ±10) C°.

2.2 Evaluation of photocatalytic activity

The photocatalytic activity of pure TiO_2 and doped with W was tested by the degradation of (MB) dye under the irradiation light (254 nm). Initially the mixture solution was stirred about 30 min in dark to obtain the adsorption equilibrium. The area of the samples 2x 2 cm^2 soaked in a 20 ml of MB to be the amount of total solution 100 ml and weight of MB 0.001g. The optimum absorption peak of MB at 666 nm used to estimate the remaining concentration of MB [10]. Plotted the ratio of remained to initial absorption of MB against irradiation time (30, 60, 90 and 120 min) to evaluate the photocatalytic degradation and calculated the percentage degradation of MB.

3. Results and dissection

X-ray diffraction patterns of theTiO_2doped with W (5%, 7% and 9%)are presented Figure (1). It can be seen that, in general, all the samples are crystalline. The pure TiO_2 is in the form of rutile phase and all the films of W-doped TiO_2 are mainly in rutile phase and appear phase of tungsten and anatase phase of TiO_2 together in the same location that give indicate about effect of dopant on the structural properties.

The small dissimilar ionic radius of WO_3 (0.62 Å) to that of Ti_{4+} (0.68 Å) could be the reason for unstabilizing TiO_2 in the form of rutile phase by replacing some portion of Ti_{4+} ions in TiO_2 lattice byWO_3+. The crystallite size was calculated by scherer equation, are (26.5 nm), (32.2 nm),(38.6 nm) and (51 nm) of pure and doped (5,7 and9 %)respectively that indicate the impurities is not substitutional.

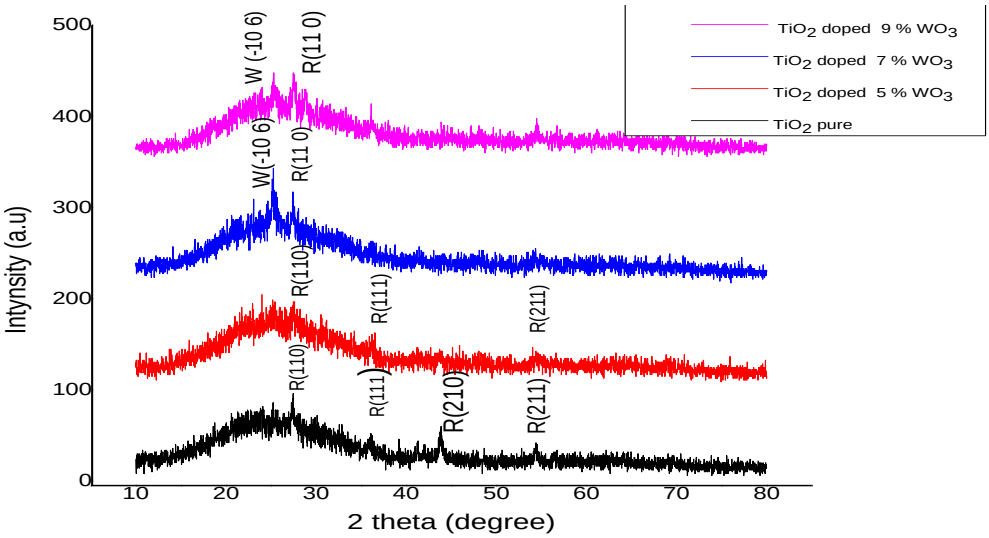

Figure 1. The effect of doping concentrations (5, 7 and 9 % WO_3) on X-RD results of TiO_2.

Figure 2 displays FESEM images obtained from different doped concentrations which indicates the crystal sizes are in nanometer range for all films. Pure TiO_2 appears as spherical particles homogeneous in size and shape; after doped by ratio 5% the shape and size of particles will differ but keeps in nano range, when doped concentration increased to 7% and 9%, the films appear more homogenous with look of WO_3 particles in the films surfaces.

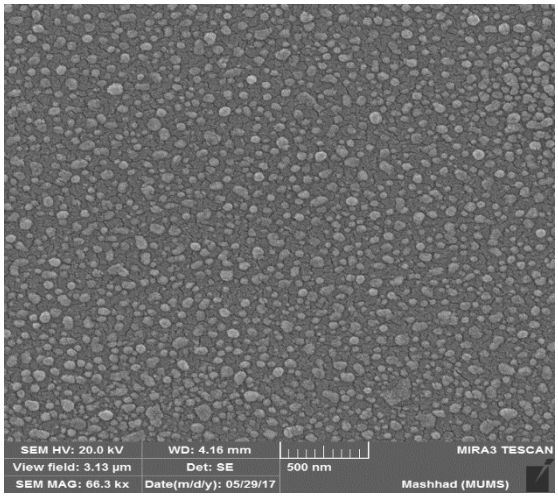
3



4

Figure 2. FESEM images of 1) pure TiO_2,2) doped 5%, 3) doped 7% and 4) doped 9%.

Figure 3 demonstrates the transmittance of undoped and doped films, transmittance decreases with increase of dopant ratio, and that is a result of creating a new energy level between valance band and conduction band inversely with the absorption. The response of $TiO_2$to visible light increases after doping with tungsten and it shows a red shift (towards higher wavelength). From the invers relation between transmittance and absorption that indicate the reduction of energy gap with doped .The red shift of the absorption curve leads to decrease in the energy band gap and also the recombination rate, which a result to the enhanced photocatalytic activity. From Figure 4, it can be seen that the energy band gap decreases with increase of dopant ratio, shift towards the visible range, which reveals increasing tungsten ratio. The red shift of the band gap caused by the presence of tungsten can be evaluated as being moderate, with the absorbance limit shifted.

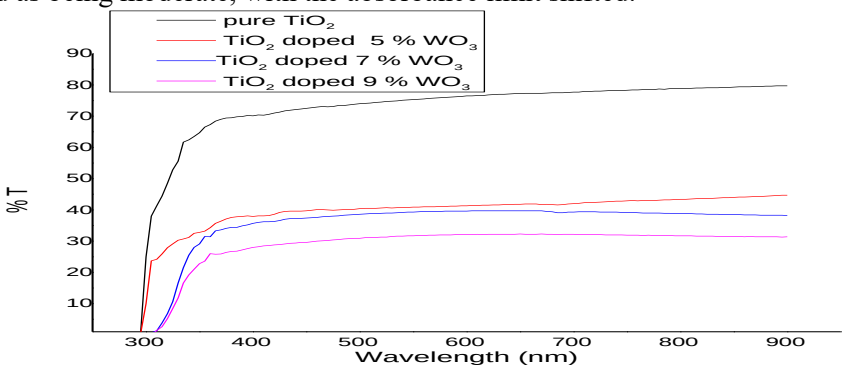


Figure 3. Explain WO_3 ratio on the transmittances.

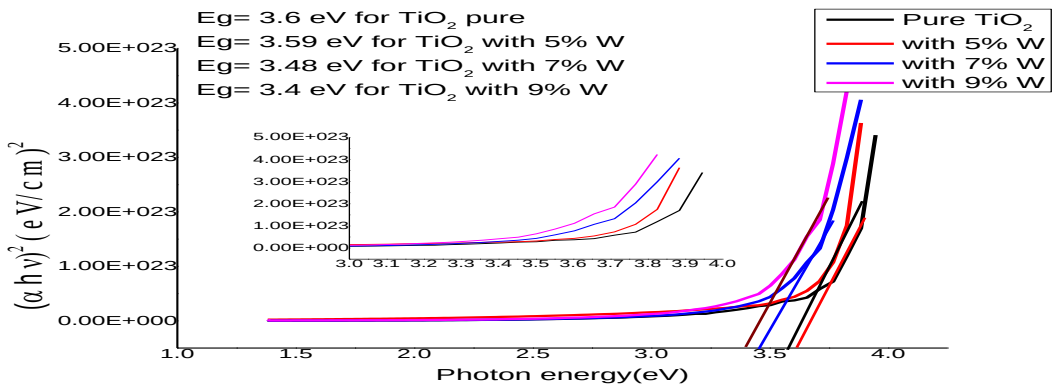

Figure 4. Explanation of the effect of doping ratio on the energy gap.

The degradation of MB dye was watched by measuring the change in absorbance as a function to the illumination time. Figure 5 explains the effect of change in illumination time on the ratio (9%). In from the Figure 5 de-colorization of MB happened after 30 min of illumination in the presence of W-doped TiO_2 and atmospheric oxygen.The reduction in the absorption of MB with illumination time is accustoming to the changes of the molecular structure of the dye.

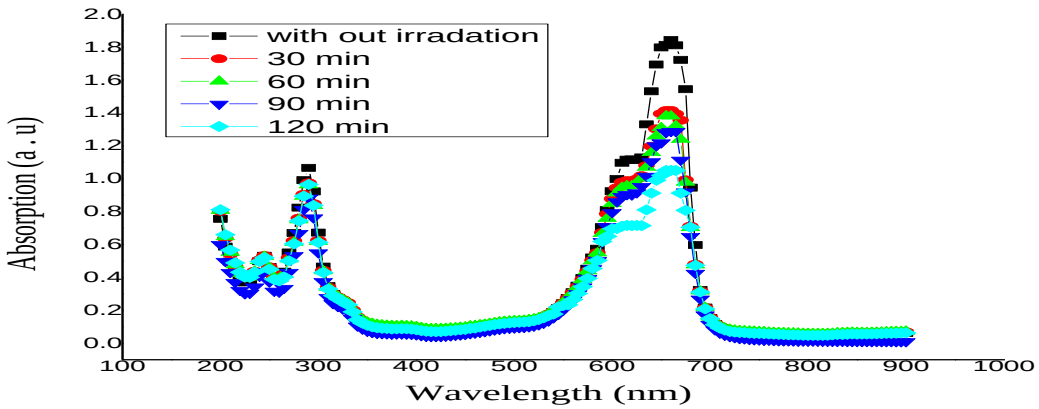

Figure 5. Explaination of the effect of illumination time on the absorption for titanium doped with tungsten at ratio 9%.

Photodegradation of MB is illustrated in Figure 6. MB concentration changes with increasing irradiated time.The decomposition of MB increase with increasing the tungsten concentration at the same time. The effects of surface area, crystal structureand ratio of dopant have been providing rational explanations for the photocatalytic activities observed.The degradation efficiency of MB increase by increasing the illumination time and dopant ratio that appear in Figure 7.

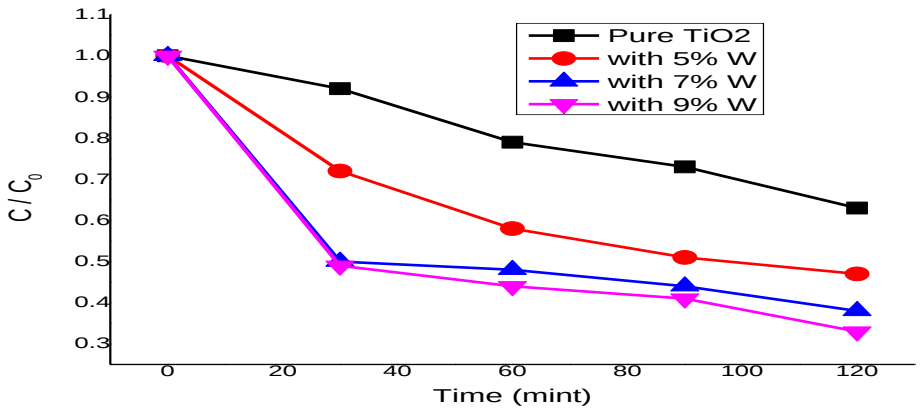

Figure 6. Photodegradation of MB under UV irradiation and time irradiation with different doped concentrations.

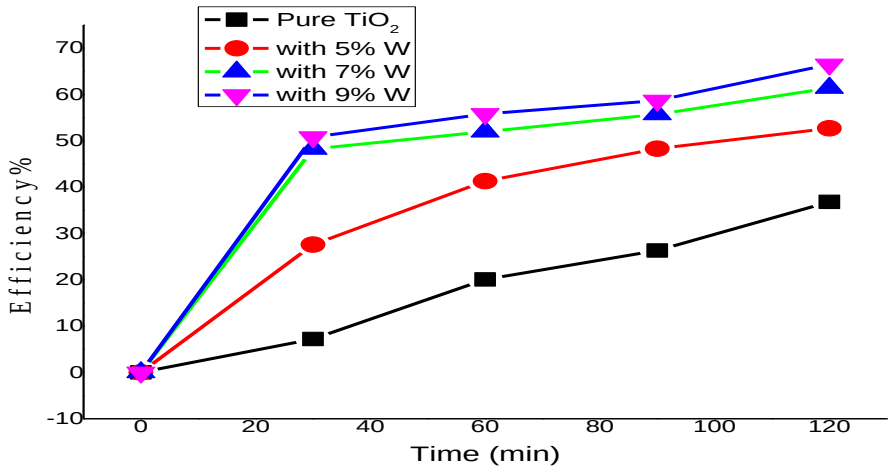

Figure 7. Degradation efficiency of MB using different ratio of W.

4. Conclusions

In this study, synthesis nano titanium dioxide by PLA method pure and doped (tungsten) and applied as photocatylist. The crystal size increased with increased ratio of doped.From FESEM, the grain size for all films in nanometer range.The increasing in doped concentration resultedin high homogenous with appeared WO_3 particles in the films surface. UV–vis spectra showed increased in the absorptionpeaks with dopant ratio.Decreasing the energy gap increased the photocatalytic activities. The addition of WO_3 as a dopant in all samples resulted in an enhancement in photocatalytic activity. From the results of photocatalytic appear optimum photocatalytic performances at dopant ratio of 9%. Also better photo degradationrate and degradation efficiency appear at the same dopant ratio.

Effect of fillers (Bentonite - Zirconium) on the thermal behaviour of PVC polymer

Effect of fillers (Bentonite - Zirconium) on the thermal behaviour of PVC polymer

Wasan K. Hasan

Education College for Pure Science, University of Kerbala, Karbala, Iraq

E-mail: wasan.kamil@uokerbala.edu.iq

Abstract. Thermal conductivity is one of the basic physical phenomena that can affect matter in heat quantities and explain what happens during the heat transfer process. The work indicates to the importance of investigate for effect of filler material Bentonite and ZrO_2 on the thermal properties of polyvinyl chloride as a binder material with ratio of 3% compared with the ratio of Zirconium Oxide which was in the limits (0%, 5%, 10%, 15%) besides Bentonite, the burn process was carried out at various temperatures 800,900,1000,1100 and1200 ^{o}C. The results showed a decrease in the values of thermal conductivity from (0.5-0.3 W/m.K) when adding zirconium oxide, while increasing the percentage of the Bentonite with increasing and the burning temperature led to the increment of thermal conductivity for the prepared samples.

Keywords: Thermal conductivity, polyvinyl chloride, zirconium oxide, polymer composite

1. Introduction

Polymeric materials are among the important materials in the industry for many reasons, the most important of which is ease of manufacture and cheap price, light weight, good chemical specifications that are not present in ceramic and metallic materials, but after technological development, especially in the field of space industries and the manufacture of cars, airplanes and boats, the need increased to manufacture materials with specifications In particular, attention has turned to the manufacture of composite materials, including polymeric composites. Most of the polymeric composite materials were the reinforcement material with ceramic or glass materials in the form of fibers or powder, where many previous studies were conducted to learn about changing the thermal properties of the composites of polymeric materials with changing the type and quantity of the reinforcement material added [1].

The aim of this study is to study the thermal conductivity of polymeric material and the effect of temperature on the thermal conductivity of matter, as the thermal conductivity is one of the basic physical phenomena through which it can be studied and how a substance is affected by heat.

2. Experimental details

2.1 Theoretical part

Thermal conductivity is a phenomenon of thermal transfer, in which energy is transferred from one location to another due to irritation of the atoms or molecules of the material due to a change in the temperature of the medium, but the conductivity mechanism in the solid materials differs from it in the liquid and from it in gases as well as differs in the conductive materials from the insulating materials. The thermal conductivity of the insulating materials has been measured on the principle of the thermal conductivity of the samples in the form of a large diameter disk relative to thickness. When there is a thermal gradient (dT/dX) during a physical medium in the direction (x) the average of thermal conductivity resulting from the difference in temperature a cross the vertical cross-sectional area of the heat flow is given by:[2]

$$\frac{dQ}{dt} = -KA\ \frac{dt}{dX} \dots\dots\dots\dots (1)$$

Since (K) represents the constant of proportionality and is called thermal conductivity and is a measure of the process of thermal selection across the material, negative sign means that the flow of heat towards the lower temperature, and the addition of negative sign in the equation is useful in making K a positive quantity, and other forms of the equation above the formula The following

$$\mathrm{Q} = \mathrm{K}\frac{\mathrm{T1} - \mathrm{T2}}{\mathrm{X}}\mathrm{At} \dots\dots\dots\dots (2)$$

It represents the basic equation for thermal conductivity, which is known as the Fourier equation, and from equation (1) the thermal conductivity is defined as the amount of heat that passes through the unit area of the material per unit of time where the thermal conductivity is proportional to the difference between the temperatures of the external surfaces of the material and is inversely proportional to the thickness, so The average of heat flow is not dependent on the absolute temperature, but on the difference in the temperature of the two sides

One of the practical methods used to calculate the value of the thermal conductivity of the insulating solid l is to expose one of the sides of the samples to a heat source and calculate the temperature at the opposite side, as the sample is placed in a thermal gradient so that the flow of heat that reaches the other side is balanced Thus, the thermal properties are calculated by calculating the influencing factors and from the methods used in measuring the thermal conductivity is the stacked disk system, or the technique of heat flow in a cylinder, and since the temperature passing through the sample is the average amount of heat passing through the disk and thus the formula will be:[3]

$$K\left[\ \frac{T_2 - T_1}{d_S}\ \right] = E[T_1 + \frac{2}{r}(d_1 + \frac{1}{4}d_S)T_1 + \frac{1}{2r}d_S T_2] \dots\dots\dots\dots\dots (3)$$

Where

ds: thickness of the disc

r: disk radius

k: the thermal conductivity of the disk S

T1: face temperature A

T2: face temperature B

T3: face temperature C

The value of E can also be calculated from the power supplied to the heating coil (H), so it is*:*

$$H = IV = \pi r^2 E(T_1 + T_3) + 2\pi r E\left[d_1 T_1 + 1/2\, d_S (T_1 + T_2) + d_2 T_2 + d_3 T_3\right] \dots\dots (4)$$

Since V is the difference in voltage passing through the coil (Volt) and the current I Amp).*(*

After calculating the value of E, it is substituted in equation (3). Thus, we obtain the thermal conductivity value (K) for the sample to be examined in units (W/m.K).

2.2 Materials used in research

2.2.1 Bentonite

Bentonite is an impure clay composed mainly of montmorillonite or calcium silicate oxide and is found in the form of powder in a gray color does not smell it.

The Bentonite or volcanic mud is a commercial name for a special type of clay consists mainly of mineral smectite .Bentonite are plenty of minerals including calcium, magnesium, silica, sodium,

copper, iron and potassium, the result is the processes of transformation of volcanic glass and mainly of hydrolytic silicate [4].

2.2.2 Zirconium Oxide

Zirconium Oxide is a single crystalline substance that transform to a tetra material increase of temperature and characteristics depend on the degree of stability and the amount of stability and quality of raw materials included in its composition and a zirconia used in this research prepared by (fluka chemie AG-CH 9770 Buchs) And its purity 99.9% [5-6].

2.2.3 Polyvinyl chloride

It is a widely used plastic material and The designation is abbreviated as PVC and it is used in a lot of applications and has been used in many industries as insulating material for electric wires, floor coverings, bottling industry, auto industry and it has distinctive characteristics in terms of high electrical insulation, strong abrasion resistance, low moisture absorption and good flexibility[7-8] .

2.3 The method of work

The basic material used in this work is bentonite powder with a granular size 75μm, and zirconium of Indian origin was added with a granular size of 100μm≥ for the purpose of improving the properties of the composite with weight ratios (5,10,15 wt%) to the bentonite powder as shown in Table(1)[9-10].

The materials were prepared and weighed with a sensitive scale and the granular size was measured by using special sieves for this purpose in the laboratory, the samples were also mixed using a mechanical mixer for two hours, and then the PVC binder was added in a percentage of (3%) and the samples were formed by Semi-dry pressing method and using a hydraulic press with a diameter of (40 mm) under a pressure of (25 MPa) and a period of time of (2 min), the sintering process was carried out using an electric furnace at normal atmospheric pressure and temperatures (800,900,1000,1100,1200) ^{o}C for a period of two hours .

For the purpose of measuring the thermal conductivity of the samples, a Lee's disk was used to calculate the thermal conductivity of the insulation materials using the device manufactured by (Griffen and George). The thermal conductivity was calculated using the equation(1) as explained in figures (1-6) that show the effect of added zirconium oxide on the thermal conductivity of the samples prepared from the compound at different temperatures.

Table 1. shows the weight ratios involved in the formation of the Bent-ZrO_2

material Matrix (Bentonite)	Add Material (ZrO_2)	Symbol
100	0	A
95	5	B
90	10	C
85	15	D

3. Results and Discussion

It's noted from Figures 1-5, that the addition of zirconium oxide led to a decrease in thermal conductivity of the materials and continues to decrease with the increase of the added ratio and the thermal conductivity is also increased by increasing the Bentonite content from (4-12)%.Where the thermal conductivity of the samples prepared was measured by the law of the thermal conductivity of the equation (3) of the figures, which shows the conductivity decrease due to the defect of the supported and added material with granules of the base material to obtain a homogeneous distribution and thus its spread easily among them and which led to obstruction the heat transfer and thus reducing

the amount thermal conductivity increases the values of weight fractures, as the presence of interfaces leads to impeding the movement of waves and the transfer of energy becomes a difficult process due to the discontinuity of the structure and the loss of part of its energy during the transition from the base material to the strengthening as shown in Table 1 [11-13].

Figures 6, 7 and 8 indicated that conductivity increased with increasing temperature and gave higher values as the insulating materials are affected at high temperatures by phonons, which represent the vibrations of the crystal lattice and are responsible for the transfer of heat in solid insulating materials, so the phonon collision process with another is considered an important process at those degrees at which the number of phonons participating in the collision process increases and this means that the thermal conductivity in this case depends entirely on the average of the free path of the phonons (the average distance traveled by two phonons for each successive collision) Whereas, phonons are the single transmitters of energy and it has a major role in the conduction process and all kinds of solid materials at high temperatures [14-15].

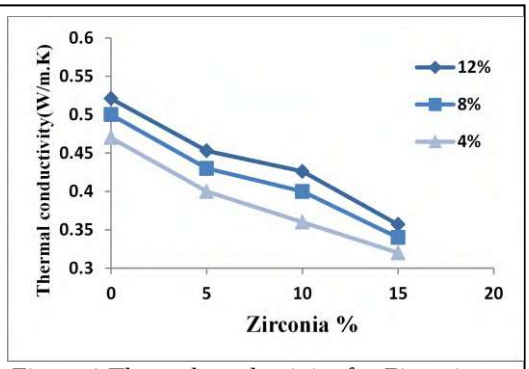

Figure 1.Thermal conductivity for Zirconia at 800 ^{o}C

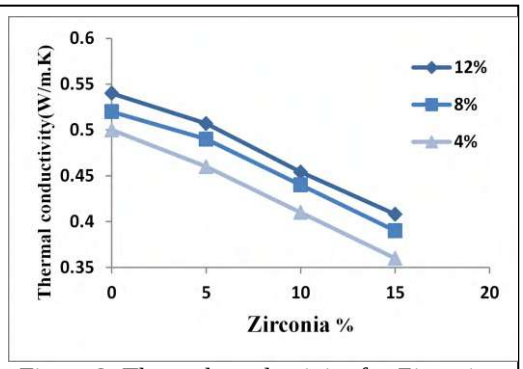

Figure 2. Thermal conductivity for Zirconia at 900 ^{o}C

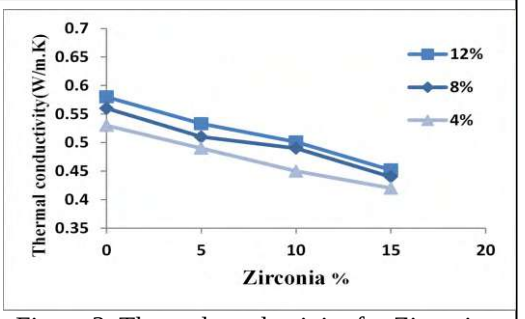

Figure 3. Thermal conductivity for Zirconia at 1000 ^{o}C

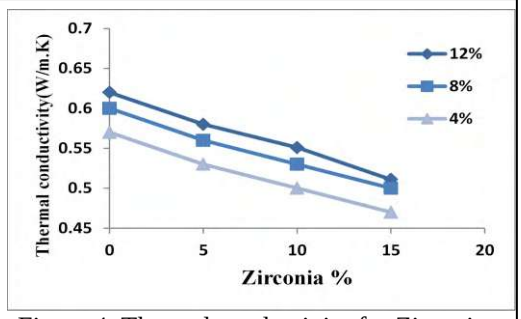

Figure 4. Thermal conductivity for Zirconia at 1100 ^{o}C

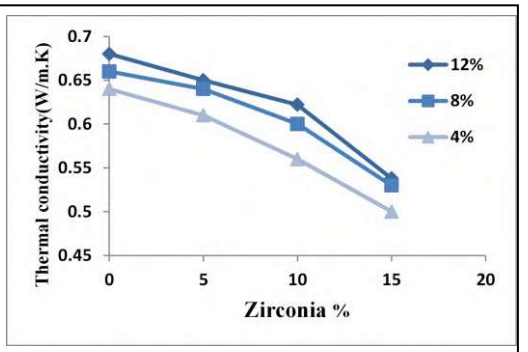

Figure 5. Thermal conductivity for Zirconia at 1200 ^{o}C

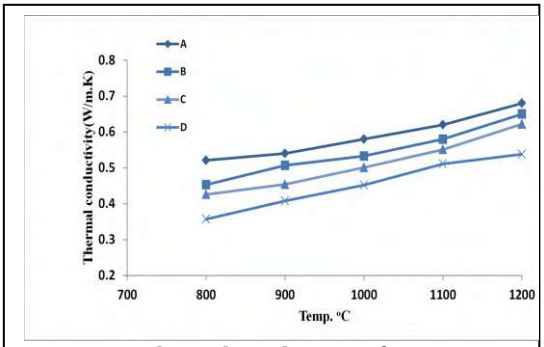

Figure 6. Thermal conductivity for Zirconia for burn degree at ratio 12%

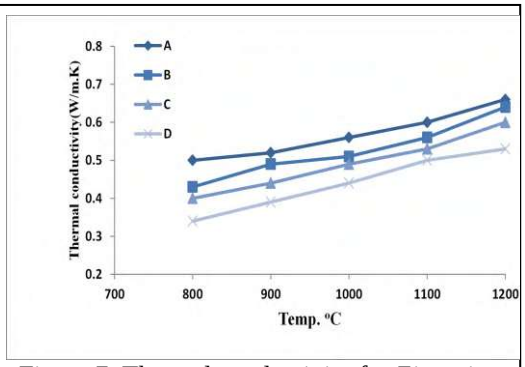

Figure 7. Thermal conductivity for Zirconia for burn degree at ratio 8%

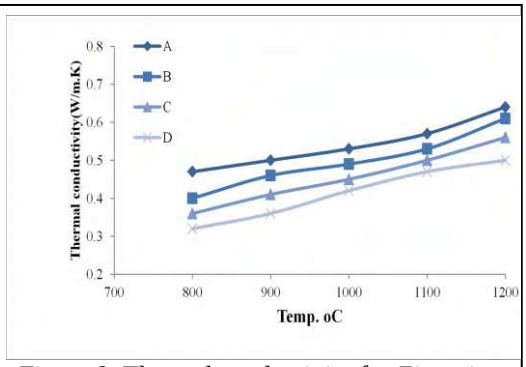

Figure 8. Thermal conductivity for Zirconia for burn degree at ratio 4%

4. Conclusions

1- The rate of addition of zirconium oxide granules resulted in a decrease in the thermal conductivity values of the polymeric compounds from (0.65 W/m.K) to(0.34 W/m.K) .
2- The thermal conductivity values increase with increasing the content of Bentonite from (0.34 W/m.K) to (0.68 W/m.K) .
3- The increase in the burning temperature led to an increase in the conductivity of all the samples, and they became of high density and low porosity, which resulted from the participation of phonons in the thermal conductivity at high temperatures.
4- The ratio of the strengthening material and the interfaces between the phases of the composite material are the reason for the low conductivity values of the polymeric compounds.
5- In the thermal conductivity test, the polymeric composite gave the highest values of thermal conductivity by increasing the burning temperature due to its influence with phonons, crystal grid vibrations, and the free path rate of the phonon.

Abstract. The calculation of charged particles density in Extensive Air Showers (EAS) that reach the earth's surface is described through estimating the lateral distribution function (LDF) at very high energies of different primary particles. The simulation of LDF is performed through the simulator of air shower which is called AIR-shower Extended Simulations (AIRES) system (2.8.4a version). The LDF simulation is performed for different charged particles like the muons, electron-positron pair production and all charged particles as well as gamma rays at very high energies (10^{16}, 10^{18} and 10^{19}) eV. The influence of the primary energies, primary particles (such as the proton and the iron nuclei) and the zenith angle (θ) on the charged particles LDF that generated in the EAS has been taken into the account. The calculation of charged particles LDF is fulfilled using "Nishimura-Kamata-Greisen" (NKG) function. The LDF using NKG function is compared with that simulated using AIRES system and gave a good agreement at high energies for (electron and positron) secondary particles, which were initiated by the primary proton.

Keywords: Cosmic rays, lateral distribution function, extensive air showers, AIRES, NKG function.

1. Introduction

The Cosmic rays (CRs) are particles hitting the earth atmosphere at a rate of about (10^3 particles/m^2 Sec). They are distinguished by their high energies. Most CRs are relativistic, having energies comparable to or somewhat greater than their masses [1, 2]. A high-energy CRs study are one of the most challenging in astroparticle physics fields. High energy CRs in the EAS detection are produced in the atmospheric Earth [3, 4]. The EAS are electromagnetic radiation cascade and ionized particles which generated in atmosphere via interaction of a primary CRs together with a nucleus of an atom in the air. Then, it produce a massive amount of the secondary particles like the electrons-positrons pair production, muons, neutrons, as well as gamma-rays, etc [3, 5]. This point of cascade development may be defined as maximum shower [6]. LDF of the charged particle in EAS is the amount required to observe the cosmic radiation of the Earth, which is often derived from EAS observations [3]. The parameter used to describe the lateral density shape can be called the parameter of the lateral profile of

NKG function "Nishimura - Kamata - Greisen function" [7, 8]. It is so important in order to perform an extensive numerical simulation of an EAS to infer the properties of the elementary cosmic ray that results in it. The number of charged particles ultra high energy CRs may be so massive and it may exceed the (10^{10} particles), so these processes require highly complex computing resources to understand and simulate them [9, 10]. Because shower growth is a complex random process, LDF depends on many independent parameters. Simulations are often used to describe the entire event from the first interaction until the electronic signal is registered to the detectors. The Monte Carlo technique is used to simulate LDF from EAS [11]. The current calculations results illustrate that the density of charged particles that reach the surface of the Earth, like the electron-positron pair production, muons, and all the charged particles, as well as gamma-rays by simulating the LDF. It is performed via utilizing the system of Monte Carlo AIRES at the ultrahigh energies (10^{16}, 10^{18} and 10^{19}) eV. The LDF was calculated for different formulas of NKG and was compared with that simulated using AIRES system.

2. Theory

2.1. Lateral Distribution Function (LDF)

LDF of the charged particles in the EAS is a required quantity of the Earth's observations of CRs. Also, it is an important quantity for CRs from the surveillance of a ground, that are mostly derived from the EAS observables [12]. Experimentally, studying of EAS can be achieved on the ground surface detectors, also underground and at numerous mountain rising via determining several quantities of the LDF, such as a density of the charged particles that produced in EAS as the function of the distance from the shower core. The LDF can be described as the shower structure of cascade at different atmospheric depths [13, 14]. An expression which is widely utilized to describe the form of LDF is a lateral shape parameter in the NKG-function [7, 8]. In 1950, Kamata and Nishimura approached an approximated analytical equation for the angular and lateral distribution of the shower particles in an approximation of cascade B theory that made by Nishimura-Kamata function. Practically, the commonly used approximation of the results of calculation proposed by Greisen, that was called (NKG-function), which summarized the research of the average characteristics of multidimensional cascades (mainly electron-photon) at ultrahigh energy CRs [15].

In 1958 Kamata and Nishimura have solved the equations of Landau for LDF of photons and electrons in the (approximation B) of the cascade theory. A solution evaluated in Moliere units appears to be the shower age function (s), characterizing the cascade development solved the Landau's equations have been reached to [7, 8]:

$$\mathbf{f(R/R_M)} \propto \left(\frac{\mathbf{R}}{\mathbf{R_M}}\right)^{\mathbf{s-2}} \left(\mathbf{1}+\frac{\mathbf{R}}{\mathbf{R_M}}\right)^{\mathbf{s-4.5}} \quad \ldots\ldots\ldots\ldots (1)$$

Where R is a distance from a shower core; R_M is Moliere radius and s is the shower age. In EAS there are hadrons, muons, photons and electrons, so that NKG-function can't directly be applied: a lateral distribution form, at least, is the function of zenith angle and energy. Therefore, there may be the distance of the core shower interval for the given essential energy (E_o), where one can neglect the contribution of muons and hadrons to the measured charged particles density and where approximately the LDF form is just the shower age function.

The lateral distribution of an electromagnetic cascade can be parameterized by the NKG-function [7, 8]:

$$\boldsymbol{\rho_e(R)} = \frac{\mathbf{N_e}}{\mathbf{2*3.14*R_M^2}} * \mathbf{C(s)} * \left(\frac{\mathbf{R}}{\mathbf{R_M}}\right)^{\mathbf{(s-2)}} * \left(\frac{\mathbf{R}}{\mathbf{R_M}}+\mathbf{1}\right)^{\mathbf{(s-4.5)}} \ldots\ldots (2)$$

where $\mathbf{C(s)}$ is the normalizing factor which is given by [16]:

$$\mathbf{C(s) = 0.366\, s^2 * (2.07 - s)^{1.25}} \quad \text{.....} \quad (3)$$

$\boldsymbol{\rho_e(R)}$ is the electrons density as a function of the distance from the shower core; $\mathbf{R_M}$ at sea level equal to 78 m; the shower age parameter (s), where the NKG-function is valid for the range 0.8 <**s**< 1.6; $\mathbf{N_e}$ is a total number of electrons in EAS that is given as [9]:

$$\mathbf{N_e = 10^6 \left[\frac{E_0}{10^{15}\ eV}\right]^{1.03}} \text{.....} \quad (4)$$

The electromagnetic cascade produces approximately most of the charged particles in the EAS and through the ionization of the electron that most of the shower energy is dissipated [17]. The results of analytical parameterizations of Monte Carlo calculations and the cascade equations solution for LDF of the electron in the air showers are depended on the function of NKG [18]. NKG function was applied with distinct sets of parameters for many years for LDF description for different components of EAS. The LDF of electrons can be expressed in a form [18]:

$$\mathbf{\rho_e(R) = N_e \frac{0.028}{R_{m.s}^2}\left(\frac{R}{R_{m.s}}\right)^{-1.2}\left(1+\frac{R}{R_{m.s}}\right)^{-3.33}\left(1+\left(\frac{R}{10\,R_{m.s}}\right)^2\right)^{-0.6}} \text{..... (5)}$$

3. The Results and Discussion

3.1. LDF Simulation using AIRES System

AIRES, a set of different programs and subroutines which are utilized for EAS simulations of particles interaction development, that initiated after high energy primary CRs interacting with the nuclei of air in atmosphere and manage all associated output data [19]. The AIRES system can provides a complete propagation of particles in the true medium in the atmosphere, through observing the Earth's curvature and the geomagnetic field features [19]. Many particles can be taken into the consideration via the simulations utilizing the AIRES system like: electron-positron pair production, muons and gamma rays. In EAS, the incident primary particles, may be proton, iron nuclei or other particles with extremely high energies up to (10^{21}) eV [19].

Figs. 1 and 2 display the simulated lateral density of many secondary's as a function of (the distance from the shower core) to the surface of Earth by using AIRES system with thinning energy (the ratio between the energy of secondary particles to the energy of primary particles) (ϵ_{th}=10^{-7} Relative) of primary particles (proton and iron nuclei), respectively. The effect of the primary energies (10^{16}, 10^{18} and 10^{19}) eV and zenith angles (θ = 0°, 10°, 30° and 45°) was taken into account density of secondary charged particles which are produced in the EAS. Through these figures, it can be noticed that the lateral density of different particles increases with increasing the primary particle energies and the density of many particles and decreases with the increasing of distance from the shower core. Figs. 1 and 2 display the possibility for distinguishing the direction and spreading the inclined primary particles on detectors in EAS arrays through the variation of zenith angles and types of primary particles.

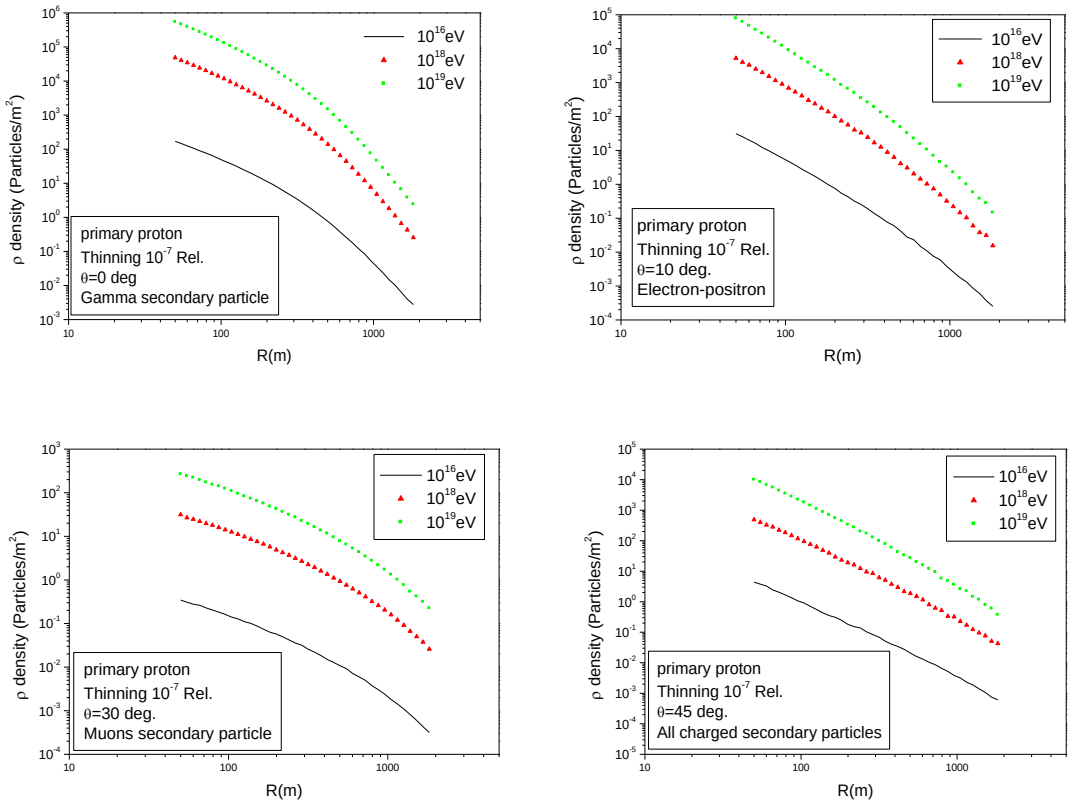

Fig.1. Effects of primary energies of primary (p) on densities of secondary particles at various zenith angles ($\theta = 0^{\circ}, 10^{\circ}, 30^{\circ}$ and 45°).

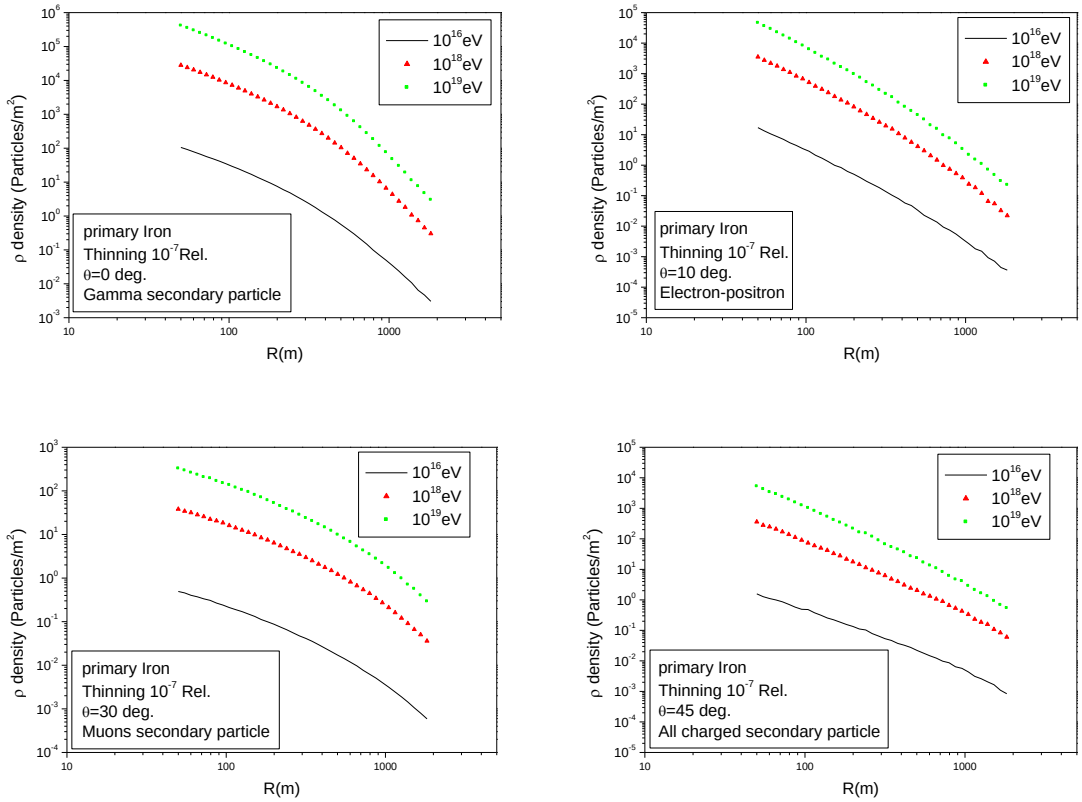

Fig.2. Effects of primary energies of primary (Fe) on densities of secondary particles at various zenith angles (θ = 0°, 10°, 30° and 45°).

3.2. Comparison between the simulated LDF of primary proton and iron nuclei

Fig. 3 demonstrates the comparison between the simulated LDF of the primary proton with that simulated for iron nuclei using AIRES system with the thinning energy ($\epsilon_{th}=10^{-7}$ Relative). This figure present a very interesting point of particles such as gamma, (electron-positron pair production), muons and all charged particles which are initiated via the primary proton and iron nuclei at the energies (10^{16}, 10^{18} and 10^{19}) eV and zenith angle (θ = 0°, 10°, 30° and 45°), which are very close to each other. Through the comparison one can demonstrates the possibility for reconstruction the type and energy of the EAS primary particles.

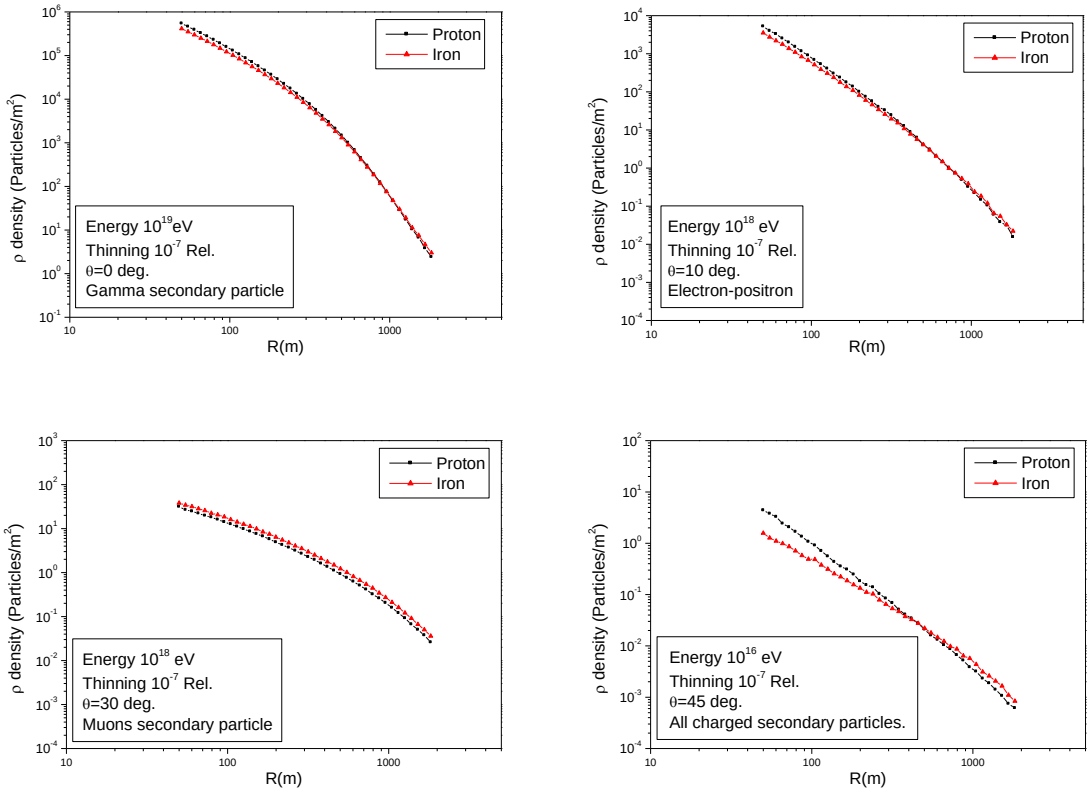

Fig.3. The comparison lateral density of the secondary particles that were initiated by primary (p and Fe) at energies (10^{16}, 10^{18} and 10^{19}eV) and zenith angle ($\theta = 0^{\circ}, 10^{\circ}, 30^{\circ}$ and 45°).

3.3. The comparison between NKG function and simulated LDF

Fig. 4 shows the comparison between the estimated LDF that performed using AIRES system with the results of NKG function that obtained from the equation (5). This figure demonstrates that the results gave a good agreement simulated data by AIRES system for electron and positron particles, which are initiated by primary proton at the energies (10^{16}, 10^{18} and 10^{19}) eV with thinning energy ($\epsilon_{th} = 10^{-7}$ Relative) for vertical showers.

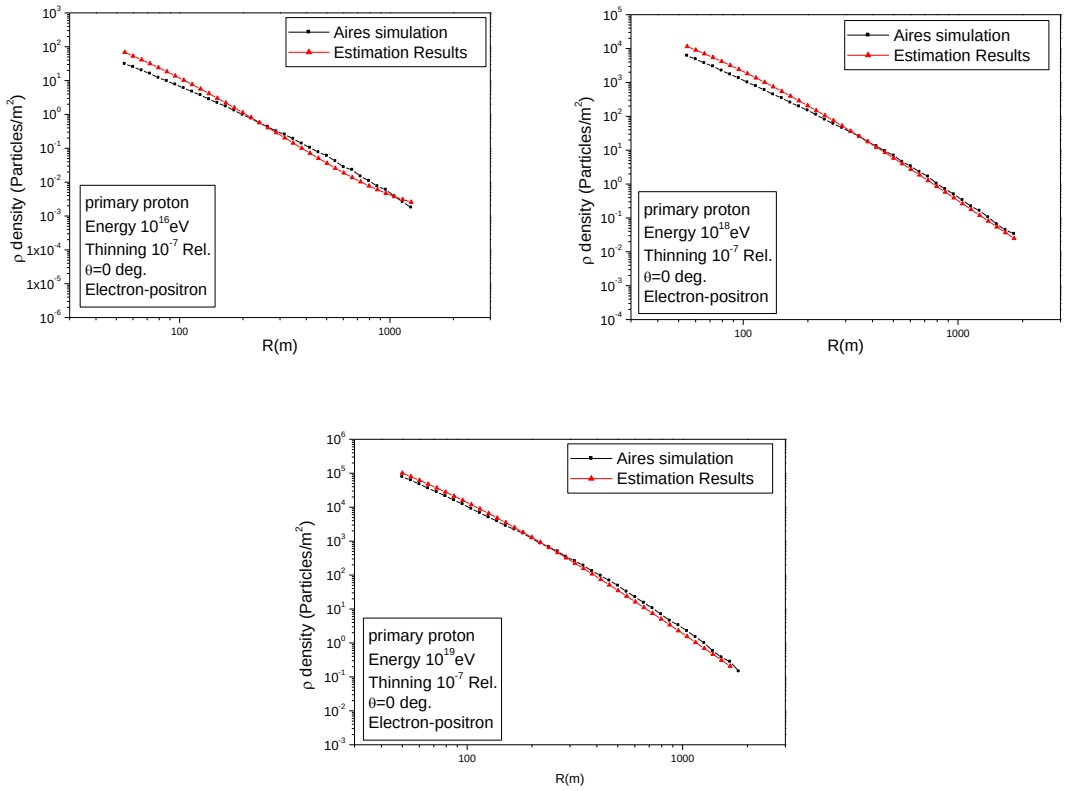

Fig. 4. Comparison between the simulated LDF with the results obtained using the NKG function.

4. Conclusions

In the present work, the effects of EAS are described by estimating the LDF at very high energies of different cosmic ray particles. The charged particles LDF like electron-positron pair production, muons, gamma rays and all charged particles that reach the Earth's surface was simulated utilizing the AIRES system for the two primaries (p and Fe) at very high energies. The influence of the primary particles, the energies, thinning energy and the zenith angle (θ) on the lateral densities of produced charged particles in EAS is taken into consideration. The simulation of lateral structure of the charged particles that reaches the Earth's surface demonstrates the capability for determining the primary cosmic ray particle and its primary energy. A significant feature of a current work is the creation of the library of samples of lateral structure which can be used to analyze real events of EAS that have been detected and also registered in the arrays of EAS.

Abstract: Wurtzite hexagonal Zinc oxide (ZnO) nanoorods and nanonails arrays have been successfully fabricated and deposited on glass substrates pre-coated with ZnO seed layer using a simple hydrothermal method. The influence of annealing temperatures of on the morphological, structural and optical properties was studied. The size and shape of the nanostructures and the band gap energy depend on the deposition temperature of ZnO thin films have been studied. The optical energy band gaps of ZnO were calculated to be 3.25 eV and 3.26 eV for the samples annealed at 300°C and 350°C respectively. The XRD results show the formation of wurtzite hexagonal ZnO structures for nanonails and nanorods arrays with prominent (002) orientation. The c/a ratio of 1.6033 is close to the ideal value for hexagonal cell around 1.633. The transmittance of the films is about 80% in the visible range. The (EDX) analysis identified the pure ZnO phase with a ratio of Z:O = 1:1.

Keywords: ZnO nanostructures, Annealing temperature, FE-SEM, XRD, Optical Band gap, Transmittance.

1. Introduction

Due to their unique electrical, optical, photonic and mechanical properties, semiconductor nanomaterials have been a rapidly growing area of research [1, 2]. One dimensional nanostructure such as nanonails appeared the most appealing sensing materials for developing gas sensor devices, since 1D, ZnO possess a good sensitivity and fast response time [3]. Nanowire, nanotubes and nanoribbons [4] have been widely studied for their important applications due to their unique optical and electrical characteristics. ZnO nanostructure is an important II–VI semiconductor, and it possesses a high electron-hole binding energy of 60 meV, with a direct band-gap about 3.37 eV, and as a result they have been used in sensors, lasers, displays, solar cells, field emissions, and photocatalysis [5–9]. Various techniques such as precipitation process, spray pyrolysis [10], thermal decomposition [11] and hydrothermal process [12] have been used to fabricate ZnO nanrods [13]. ZnO could be easily grown; and it is suitable for industrial and medical applications due to its diverse properties which depend on their morphology [14]. The well-adjusted arrays of ZnO rods were grown by a simple hydrothermal method on glass substrate using autoclave, and the samples are post annealed at different annealing temperatures. It is familiar that hydrothermally grown ZnO nanostructures have many imperfects due to

their growth temperatures [15]. Therefor the qualities of ZnO nanostructures have been improved by reducing the defects via thermal treatment process of the synthesized thin films. The results illustrate the well oriented ZnO naorods and nanonails arrays grown directly on glass substrate, as well as the effect of annealing temperature on ZnO nanostructures, size, shape and band gap energies with the use of seed layers as pre coating layers without any catalysts or surfactants at high temperature of 180 ^{o}C of the autoclave.

2. Experimental

2.1. Preparation of ZnO Seed Layers

The solution prepared from mixing of Zinc acetate dehydrate $(CH3COO)_2.H_2O$ with a concentration of (10mM) into 50 ml ethanol and stirred ultrasonically for 15 minutes. The solution was deposited by drop casting on top of cleaned glass substrates and dried on a hot plate at 80°C for 2 minutes. Finally, all the films were annealed by using a hot plate in air at 350 °C for 30 minutes to improve the film adhesion to the substrate. Vertical alignment of ZnO nanonails and nanorods were also improved by annealing process of ZnO seeds. ZnO film growth was conducted by using hydrothermal process.

2.2 Growth of ZnO nanonails and nanorods

After ZnO seed layer deposition, the seeded substrates were placed vertically in an autoclave which contained a growth solution at 180 °C for 6 hours in an oven; taking into account that the seed laye'sr substrates were facing downward. The growth solution prepared from mixing each of hexamethylenetetramine and Zinc nitrate hexahydrate of the same molarity of (25 mM) into 50 ml deionized water and the mixture stirred ultrasonically for 15 minutes. After the growth operation, the samples were rinsed by deionized water (DW), to remove the inorganic residuals from the surface of the films. Finally, all the films were annealed by using a hot plate at 300 and 350°C for 90 min.

2.3 Characterization

The structural composition of the films was examined by using X-ray (6000 XRD, Cu-k_α beam of λ=1.54). The morphologies of all samples were inquired by field emission scanning electron microscopy (FE-SEM; Model Mira3-XMU, TESCAN, Japan). And the thin films composition was analysed by EDX technique. The optical transmittance of the samples was evaluated in the wavelength range of 200–900 nm by double beam UV- visible spectroscopy -2600 from Shimadzu Co. Japan.

3. Results and Discussion

3.1. XRD analysis

Fig.1 represents X-ray pattern for zinc oxide nanostructure prepared by hydrothermal route. Annealed samples have polycrystalline hexagonal (wurtzite) structures. 2θ has three strong peaks observed at 31.76°, 34.45° and 36.25° attributable to ZnO (100), (002) and (101) crystal planes, respectively, (in agreement with ICDD card No. 036-1451 for ZnO). The strong ZnO diffraction peak (002) agrees with the highly oriented c-axis growth along this direction which was observed in the FE-SEM images to be shown later. From Fig. 1, we also observe that the intensity of (002) peak decreased with increasing annealing temperature up to 350℃, which means that the sample annealed at 300℃ has better crystal quality than that annealed at 350℃. This is due to the heat treatment the films were exposed to which is compatible with the previous study[16].

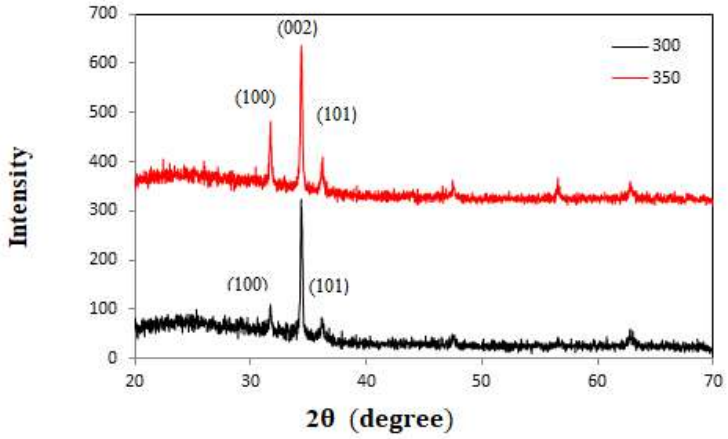

Figure 1. XRD patterns of the annealed ZnO nanonails and nanorods at annealing temperatures 300 and 350℃ respectively.

Table 1. Estimated structure parameters with dislocation density of (002) peak position

Annealing Temperature (℃)	D (nm)	ao(Å)	c_o (Å)	Ratio c_o/ao	Dislocation Density δ x 10^{14} $(line^2/m^2)$
300	43.097	3.2498	5.2104	1.60329	5.3840
350	43.519	3.2505	5.2117	1.60335	5.2801

Table 1 compares two samples annealed at 300℃ and 350℃ which estimate the structure parameters with dislocation density for the most prominent peak position (002).
The lattice parameters (ao and c_o) are calculated from the relation [17]

$$d_{hkl} = \frac{a}{\sqrt{\frac{4}{3}\left(h^2+k^2+hk+\frac{l^2 a^2}{c^2}\right)}} \quad (1)$$

Crystal lattice parameters for thin films annealed at a temperature of 300℃ are ao = 3.2498 Å, c_o = 5.2104 Å, and the ratio of c_o/ao is 1.60329, while for thin film annealed at 350℃ ao = 3.2505Å, c_o = 5.2117Å and the ratio of c_o/ao is 1.60335. The ratio c_o/a_o for both annealed temperatures has the values very close to each other, while the ideal value for hexagonal cells is c_o / ao = 1.602 [18]
Scherer's formula is applied for grain size calculation:

$$D = \frac{K\lambda}{\beta cos\theta} \quad (2)$$

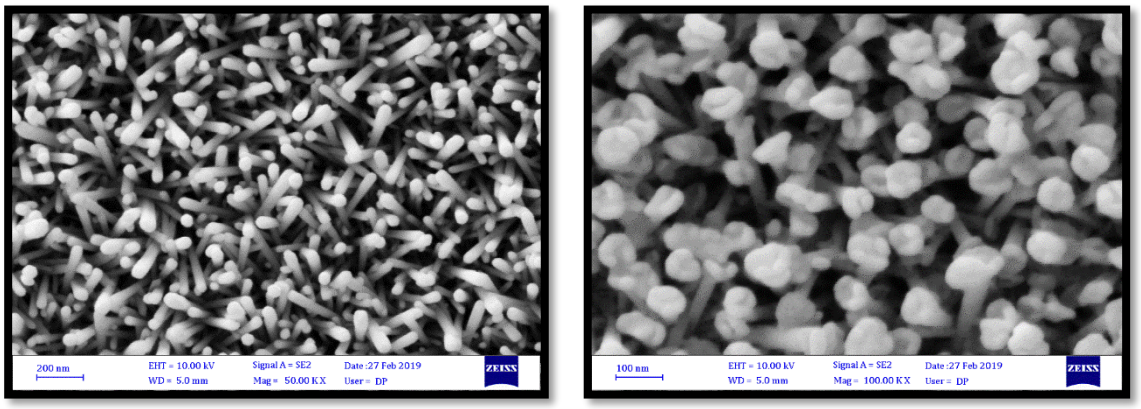
where D is stand for a grain size
λ is applied wavelength (1.5406 Å)
β: Full Width at Half Maximum of the peak (FWHM).
θ: diffraction angle
The thin film undergoes dislocations in its structure due to the heat treatment process. Therefore, the dislocation density is calculated by the equation [19], which decreased slightly with increasing temperature for 50℃.

$$\delta = \frac{1}{D^2} \quad (3)$$

whereδ is the dislocation density

3.2. FE-SEM study
The morphology of the synthesized ZnO nanorods and nanonails was examined by FE-SEM. Fig.2 shows the top view images of the films annealed at two different annealing temperatures. From fig.2

(a), It is observed that the surface structure of the films is made up of nanorods form as groups of highly dense nanorods and crystallized along the direction of c-axis of ZnO, were all arranged in vertical direction on the surface of the glass substrates. They covered the entire surface, and they were relatively smooth, had uniform surface, and were characterized by hexagonal structure and symmetrical shapes, except for the nanonails film fig.2 (b) which annealed at 350℃ is consisting of a shank-nanorod and a lotus-shaped head [20]. The process of the growth in such a structure can be described in two steps. First, the nanorod grows along the c-axis by alternating the atomic layers (O) and (Zn), and secondly the head or upper face growth in the c-axis direction and its diagonal growth accelerates, leading to the formation of a hexagonally shaped nanonail head, and this in itself has many applications like photovoltaic, etc [21].



(a) (b)

Figure 2. FE-SEM Surface morphologies (a) ZnO nanorods annealed at 300 °C, (b) ZnO nanonails annealed at 350 °C

It was also observed that the nanorods were vertical to the substrate, and on the upside, it appeared slightly tilted. The length and alignment of the nanorods were related to the seed growth mechanism. The (ZnO) nanorods mean diameter was calculated by use of Image J software. This clearly shows that when the annealing temperature increased from 300 ºC to 350 ºC, the average diameter nanorods also increases from 47 nm to 71 nm respectively. Figure 3(a, b) shows the spectrum of the energy dispersive x-ray, of both samples annealed at 300°C and 350 °C. A representation of the elements percentage in the matrix films is shown in the inset tables. The amount of these elements is represented by the intensity of the peaks, and distinctly shows the 1:1, Z:O elements. No element contamination detected in the films structure .The analysis of the samples by (EDX) technique notably show that the films prepared by hydrothermal method had pure Zinc oxide phases, and the quantitative analysis data was close to that of bulk ZnO [22].

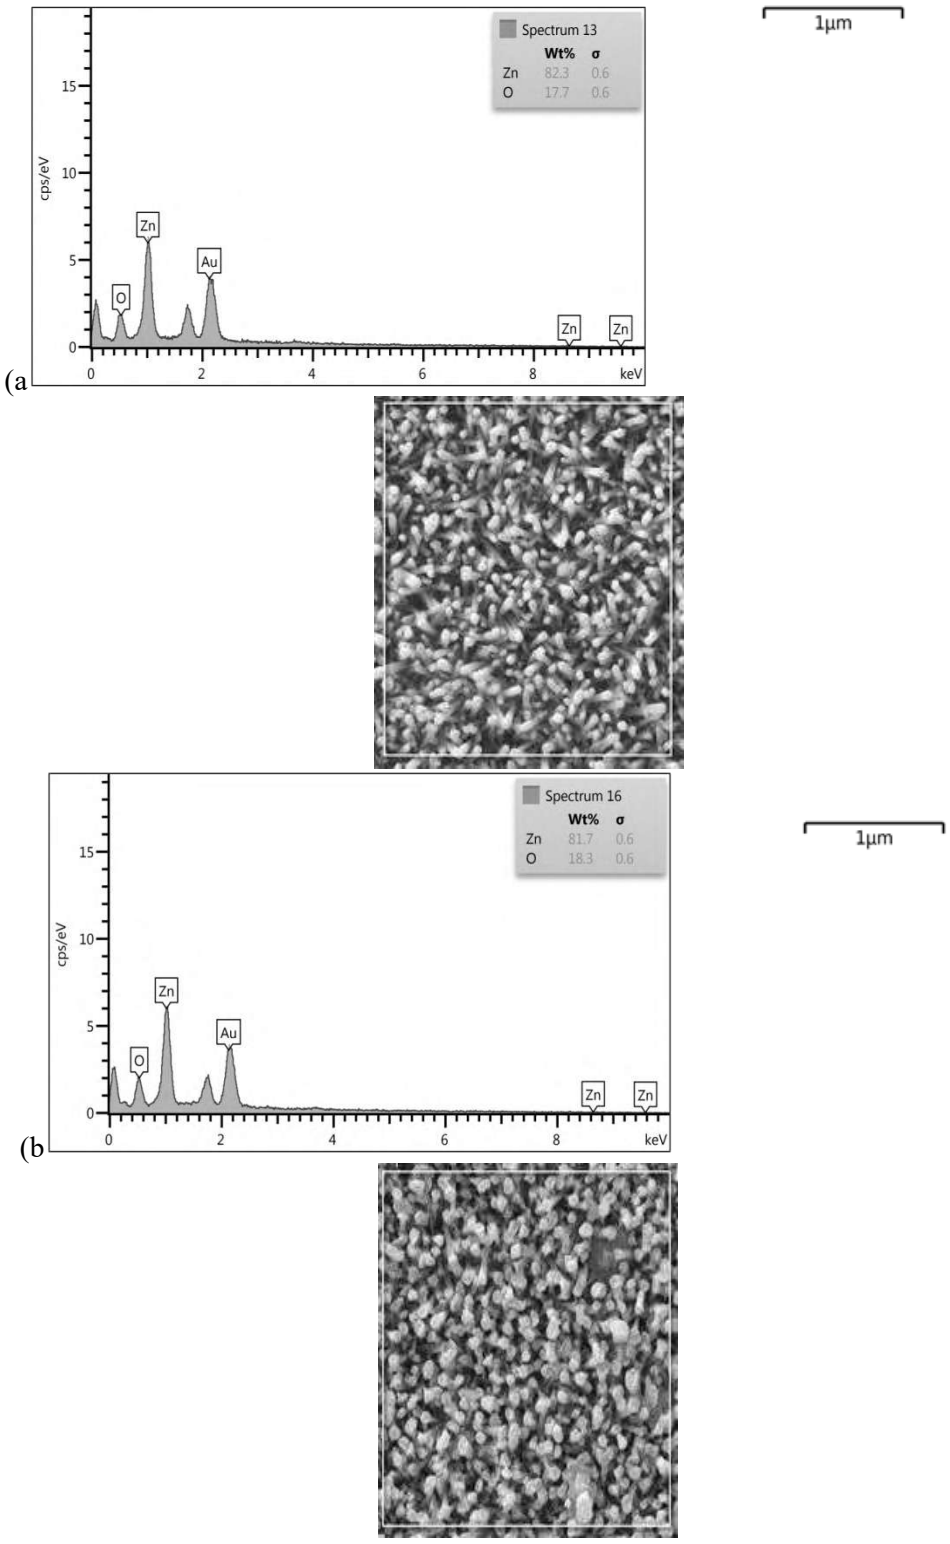


Figure 3. EDX results of a) ZnO nanorods annealed at 300°C b) ZnO nanonails annealed at 350°C.

4. Optical study of ZnO nanorods and nanonails

Fig.4 shows the optical transmittance spectrum in the UV-Visible region of (200 – 900) nm of the zinc oxide nanorods and nanonails annealed at 300˚C and 350℃ for 30 minutes. The transmittance is slightly more than 80% in the range (450 nm to 850 nm) for both films. At 360 nm there is acute absorption edge, which is resulting from the direct band gap of ZnO [23].

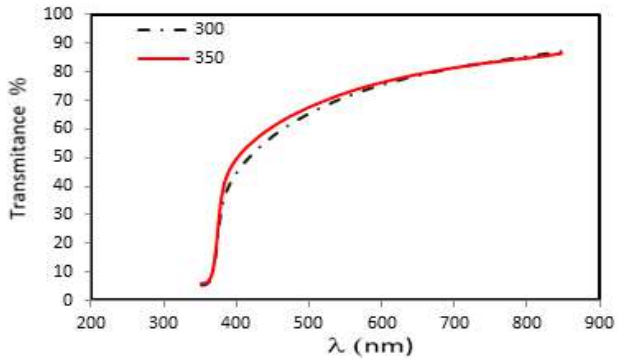

Figure 4. Transmittance spectrum for samples with variations annealing temperature of 300℃ and 350 ℃.

Zinc oxide, ZnO nanorods and nanonails are evaluated by extrapolation of the linear connection between $(\alpha h\upsilon)^2$ and hν which is consistent to the equation below [24]

$$\alpha h\upsilon = A(h\upsilon - \mathrm{E}_g)^n \quad (4)$$

where α, and hυ, are the absorption coefficient and the photon energy respectively. Eg is the optical band gap and A, a constant. Fig. 5 describe the graph of $(\alpha h\upsilon)^2$ against hυ. The direct optical band gap value Eg of the films is estimated from the curve interception of $(\alpha h\upsilon)^2$ vs hυ plot. The existence of a single slop in the curve implies that the ZnO film has direct and allowed transition. The annealed ZnO nanorod and nanonails band gap value at temperatures of 300℃ and 350℃ was found to be (3.25 and 3.26) eV, respectively. This is due to increase the annealing temperature which accelerates the formation of crystals and slightly increases its band gap [25].

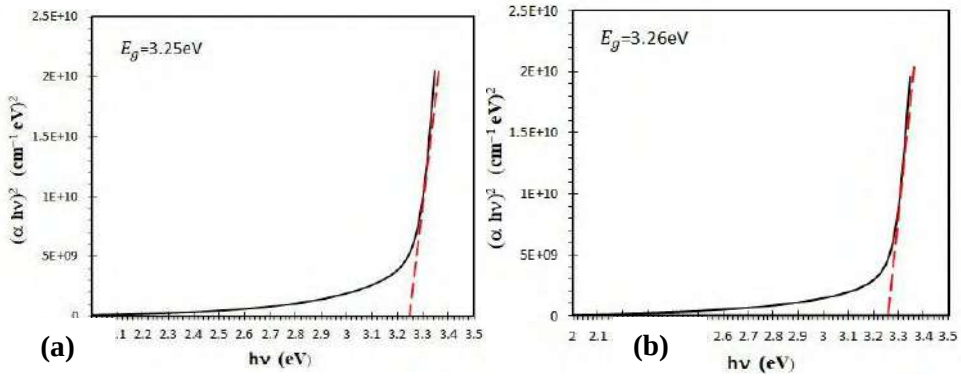

Figure 5. The relation between $(\alpha h\upsilon)^2$ and (hυ)for ZnO nanorods (a) annealed at 300℃, (b) annealed at 350 ℃

5. Conclusions

The hydrothermal process is a simple and efficient method. It has received an increased attention due to its implicitly. In this paper, we presented the synthesis, structure characterization, and properties of nanorods and nanonails structure arrays for ZnO thin films prepared by hydrothermal technique and annealed at temperatures of 300℃ and 350℃. Highly preferential growth of ZnO nanorod and nanoails

along the c-axis orientation was observed with hexagonal wurtzite structure. The average diameter of the ZnO nanostructure obtained from the FE-SEM by using image J analysis increased clearly from (42 nm to 71 nm) for nanorods and nanonails respectively with increasing annealing temperature from 300 ºC to 350 ºC. The intensity of (002) peak was decreased by increasing the annealing temperature while the transmittance and the optical band gaps (3.25 and 3.26) eV, were slightly increased. The energy dispersive x-ray (EDX) analyses of the samples obviously show that the films synthesized by hydrothermal method have pure zinc oxide phases. It is evidence from the results that the nanostructure properties like size, shape structural characterization and optical band gapes can be tuned according to the synthesis temperature which leads to tuning the nanostructure materials properties for a certain applications.

Abstract. Cadmium Sulfide (CdS) nanoparticles were synthesized hydrothermally at various reaction temperatures (140, ,160, 180,200) ° C. Crystal structure and surface morphology were studied corresponding to the reaction temperature. The X,-ray diffraction results, reveals that CdS nanoparticles were prepared have high crystallinity with polycrystalline nature and hexagonal wurtzite phase. The preferential orientation was along (002) and (110) planes. The average crystallite size was tended to increase with the increase of reaction temperature which about (21-24) nm. The structure parameters such as dislocation density and microstrain was examined. CdS nanoparticle images in Field Emission Scanning Electron Microscopy (FESEM) indicates rounded ball (cauliflower), the particle size was in the range of (23-245) nm and the smallest size was obtained for the nanoparticles at reaction temperature 200 °C. The antibacterial activity of cadmium sulfide CdS nanoparticles was estimated against two types of common bacteria (Gram-negative Escherichia coli and Gram-positive Staphylococcus aureus). It was found that there is a strong antibacterial activity and the greatest effect was for the prepared nanoparticles at reaction temperatures 160 and 180 oC, and the highest activity was found against (E. coli) bacteria as well as with the increase of nanoparticles concentration. This work combines microbiology and nanotechnology, perform probable advances in the formulation of a new kind of antibacterial.

Keywords: CdS nanoparticles; Hydrothermal method; structure properties; Antibacterial activity; Escherichia coli; Staphylococcus aureus.

1. Introduction

Cadmium sulfide (CdS) is currently an extremely interesting, semiconductor compound from the II-VI group of the periodic table with a direct band gap of 2.42 eV and conductivity n-type, it has three types of crystal structures, namely rock, zinc, and rock-salt[1]. The würtzite phase among these three phases is the most stable and simple to synthesize [2]. Therefore CdS is high potential used as sensitive photodetectors [3] heterojunction diodes, solar cells, and semiconductor devices [4]. CdS nanomaterial can be used in various life sectors due to their higher stability, outstanding electrical, Structural and chemical properties, affordability, ease of processing and handling [5]. CdS nanoparticles and thin films were widely synthesized using different chemical and physical methods due to its enormous range of applications in various fields of life, like solvothermal and hydrothermal

techniques [6, 7], thermal evaporation method [8], chemical bath deposition [9], Laser Ablation in liquid[10], spin-coating technique [11]. Cadmium sulfide and chalcogenide nanoparticles can easily prepared by using the hydrothermal method[12]due to its essential Advantages including cost-effectiveness[13]Particle size controllable, low temperature and techniques less complicated [14].Compared to organic antibacterial agents, the antibacterial activities of inorganic compounds are of great interest due to its durability, toxicity, heat resistant, selectivity and etc. [15]. The antibacterial activities of CdS nanoparticles were evaluated against different types of bacteria by Ayodhya et al. [16], which is very promising in displaying their capability to inhibit and destroy both types of gram positive and gram-negative pathogenic bacteria. Abd-Elkader et al.[17]. The antibacterial efficacy of CdS thin films deposited with CBD was evaluated, against Gram-positive and Gram-negative bacteria in dark and sun light at 60 ^{o}C. They found that, CdS thin films have noticeable antibacterial activity in sunlight and dark and it could be used as antibacterial and antimicrobial agents in the application of medical field. Narasimmana et al.[18] Studying the impact of Zr concentration on the antibacterial properties of the CdS thin film, doped films display excellent antibacterial performance against K. Bacterium pneumonia (gram −ve) making it ideal for pharmaceutical applications. Whereas Gajendiran et al. [19] worked on fabricate CdS quantum dots nanoparticles for biological applications, the antimicrobial activity against S. Aureus bacteria were found to be an impressive antibacterial agent against gram-positive bacteria by prepared nanoparticles. In the current work the effect of reaction temperature on structural surface morphology of CdS nanoparticles was investigated and the antibacterial activities the Gram-negative Escherichia coli and Gram-positive Staphylococcus areus was carried out using agar well diffusion method in order to establish their suitability for medical applications.

2. Materials and methods

Cadmium Acetate $(CH_3.COO)_2Cd.2H_2O$ from (BDH) England, Thiourea $NH_2.CS.NH_2$ from (THOMAS BAKER) India, Acetone $(CH_3)_2CO$ (TEDIA) from USA, Ethanol (C_2H_5OH) from (BDH) England, Mueller Hinton II. agar MHA from (Biolab Zrt) Hungary were used to synthesized CdS nanoparticles by the Hydrothermal method. (0.3 g) of cadmium acetate $(CH_3.COO)_2Cd.2H_2O$ and (0.9 g) of thiourea$NH_2.CS.NH_2$dissolved in 40 ml of deionized water with a ratio of (1:3).The solution was well mixing by magnetic stirrer for 30 min. Then40 ml of the prepared solution was added into the Teflon-lined stainless-steel autoclave and heat up in an oven at reaction temperatures (140,160,180 and200) °C for 4 h, and allow it to cool to room temperature. The resulting solution was separated by centrifuge (Frontier 5706), for 10 min at 5000 rpm to get a deep-yellow powder. the precipitating substance (CdS) was washed twice with deionized water and absolute ethanol (C2H5OH)purity(99.9%), and then dried at 70 °C.

The antimicrobial activity CdS nanoparticles ws evaluate against two different types of clinical bacteria Gram-negative Escherichia coli and Gram-positive Staphylococcus aureus using the agar well diffusion method. Standardized suspension of each tested bacteria (1.5x108cfu/ml) by Densi Check standard (0.5N) was swabbed separately onto Mueller Hinton agar plates using sterile cotton swabs. The agar was punched with sterilized cork borer 9 mm and 100µl from each the CdS nanoparticle were added into the four holes for four concentrations (1000, 500, 250, 100) µg/ml after making dilution at well Petri dishes were incubated for 24 hours. at 37°C, after incubating, the inhibition zones were measured in millimeter diameter. The crystalline structure of the CdS NPs examined by X-ray diffractometer (Shimadzu XRD-7000 (JAPAN), the source of X-ray radiation is Cu kα1 radiation the scanning angle varied in the range (15-70)° with wavelength 1.54056 Å, speed 1deg/min, current 80 mA, and voltage 60 kV. The morphological confirmation of various CdS nanparticles was carried out by Field Emission Scanning Electron Microscopy (FEI FESEM Nano SEM Nova 450).

3. Results and discussion

3.1. Structural analysis.

The XRD patterns of CdS nanoparticles obtained at different reaction temperatures was identified by the presence of diffraction peaks at scattering angles (2Θ) of 25°, 26.6°, 28.2°, 43.8°, 48°, 52°, 52.9°,54.8°, and 58.2° that were indexed to the (100), (002), (101),(102), (110), (103),(112) and (201) planes, all peaks of diffraction can be indexed to the pure hexagonal CdS structure according to the according to the standard (JCPDS No. 77-2306), the diffraction pattern refer that CdS is polycrystalline structure, sharp and strong peaks indicate that the CdS has crystallized well [20] as shows in Fig.1.

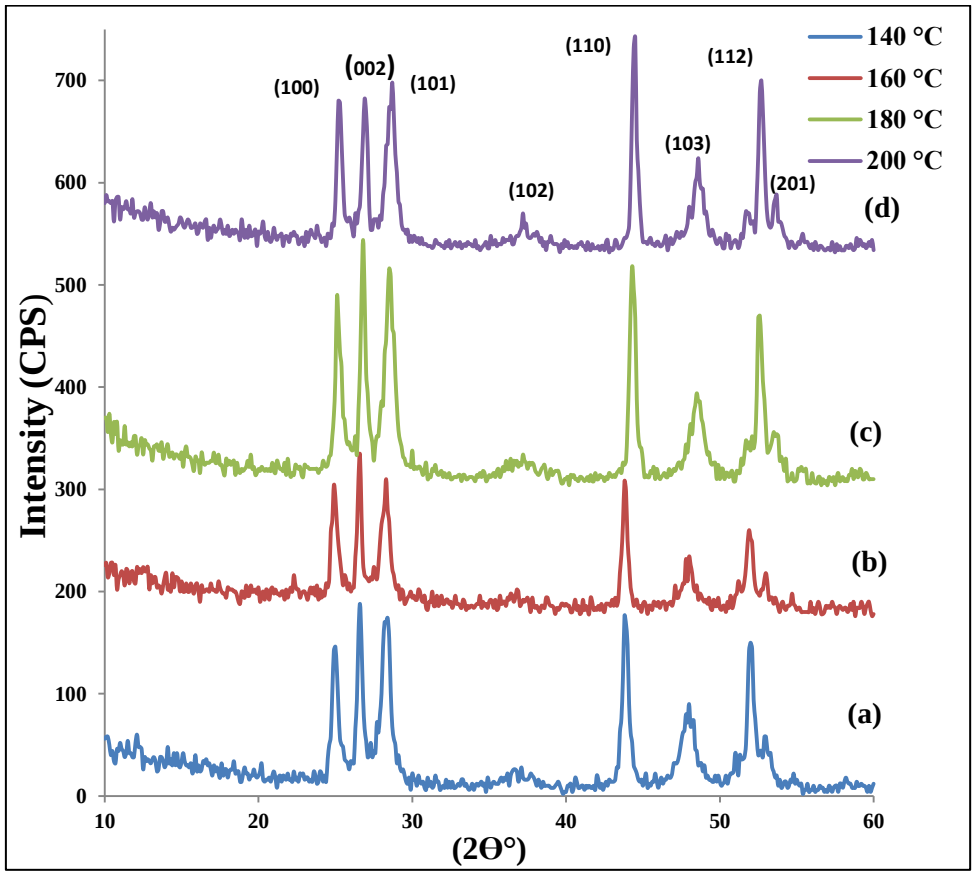

Fig.1. Diffraction pattern obtained from CdS XRD at 4 h reaction temperatures: ((a) 140, (b) 160, (c) 180 , (d) 200)°C.

The high intensity sharp and narrow XRD peaks confirmed that grown CdS nanoparticle were highly crystalline. All diffraction peaks can be indexed tothepure hexagonal structure of CdS according to the standard card (JCPDS No. 77-2306) and no otherpeaks related to impurity phases were observed. The XRD peaks of CdS nanoparticle became narrower with shifted of peak position with increase temperature, this indicate an enhancement in crystalline quality, this agreement with study [20]. For the hexagonal structure the interplanar spacing (d), lattice constants (a) and (c) were calculated using the following equation [21].

$$\frac{1}{d_{hkl}^2} = \frac{4}{3}\left(\frac{h^2+hk+k^2}{a^2}\right) + \frac{l^2}{c^2} \qquad (1)$$

Table 1 displays the structural parameters determined, values obtained that are too close to the values seen in the investigation (a=b= 4.136 and c= 6.713) (JCPDS-77-2306) which confirms wurtzite structure [22], the average crystallite size (D) of the CdS nanoparticles was determined with the formula of Debye Scherrer [23]:

$$D = \frac{k\lambda}{\beta\cos\theta} \qquad (2)$$

β is the full width at the maximum half of the peak of diffraction, K is known as the 0.9 shape factor and λ is the X ray diffraction source wavelength. The average grain size for Preferred orientation (110) is within the range (18.8678- 24.1725) nm as illustrated in the Table 1. The crystallite Size for (110) preferential orientation is a gradual increase, this refers to improve crystallization with increasing reaction temperature. The constants of lattice 'a' and 'c' contracts the (c/a) values remained constant about 1.63 approximately for all the nanoparticles and nanostructure thin films, this is an agreement with the literature [18, 20].

Table 1. Structural parameters of CdS nanoparticle obtained from XRD data as a function of preparation temperature for (110) preferential orientation.

CdS nanoparticles At:	$2\theta^o$	d_{XRD} (Å)	Crystallite Size D (nm)	a=b (Å)	C (Å)	V (a^2c) $(Å)^3$	c/a
140 °C	43.8	2.06233	18.8678	4.1246	6.665	113.403	1.6289
160 °C	43.9	2.06423	22.5634	4.1284	6.6697	113.679	1.6282
180 °C	43.81	2.06331	18.8207	4.1266	6.6678	113.546	1.6306
200 °C	44.01	2.05841	24.1725	4.1168	6.6577	112.836	1.6276

3.2. Morphology analysis

Fig. 2a, b, c, d show FESEM images of CdS nanoparticles prepared at reaction temperatures of 140,160,180,200°C respectively. The surface morphology consist of homogeneous and densely packed distribution of well-defined grains, which includes small and large particles and has a regular shape with fine particle size, Fig. 2 indicate a rounded ball (cauliflower) like nanospheres these results was consistent with literature [24-26].

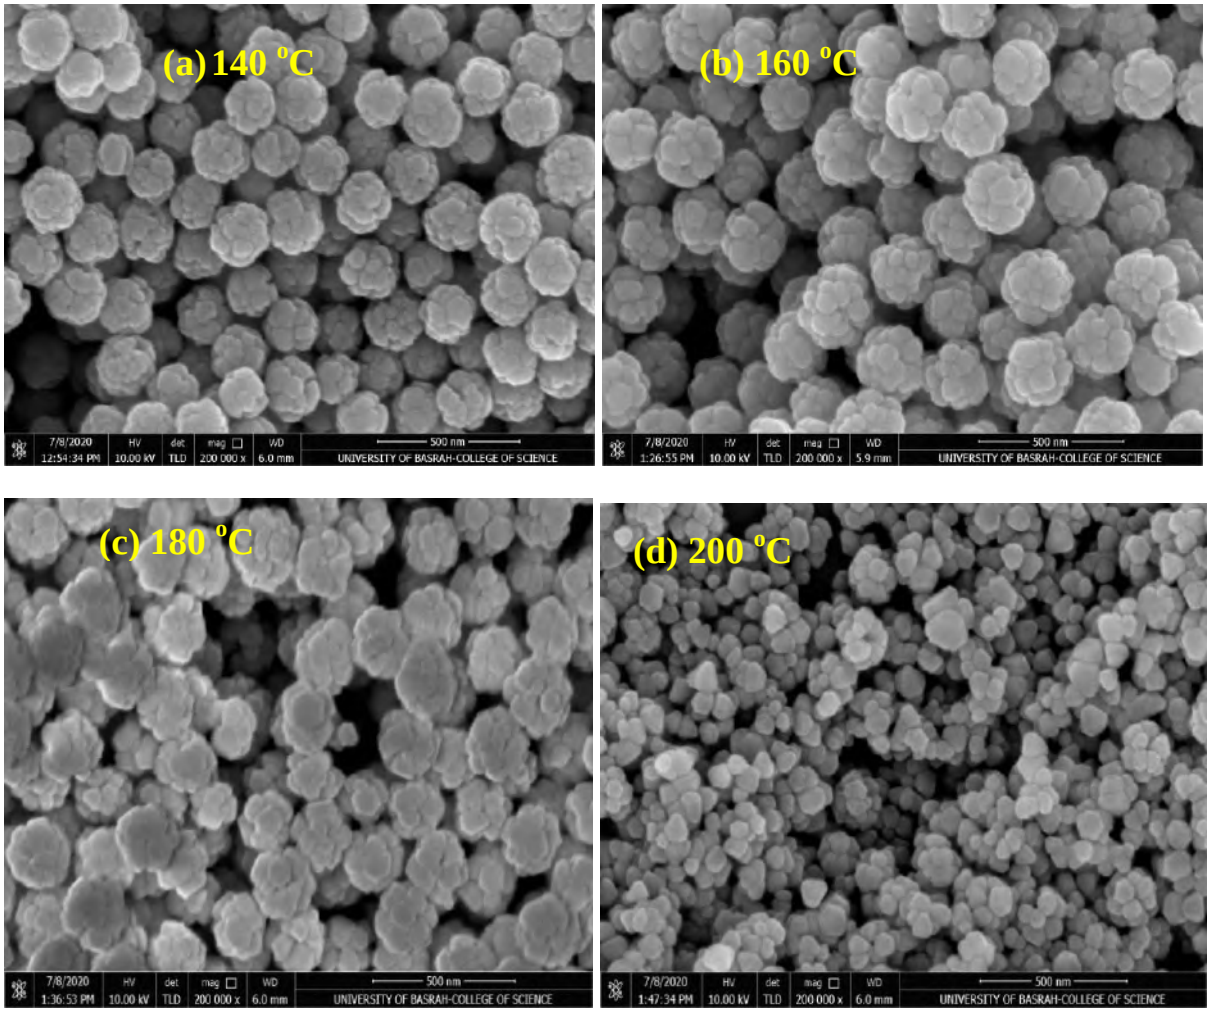

Fig.2. FESEM image of CdS nanoparticle (cauliflower) at reaction temperatures: (a) 140 °C, (b) 160 °C, (c) 180 °C, 200 °C.

CdS nanoparticles have an average grain size of around (94-245) nm, The particle sizes were measured by defining the known length of the FESEM scale bar as shown in Fig. 2a, which indicated the formation of microspheres (cauliflower) of CdS (160,180)°C and the majority of the particles looked in the range of about (138-209) nm, meaning, there is no noticeable change (whether in size, shape, or clusters) compared to the first model(140°C) as shown in the Fig. 2b, c respectively. The sample microspheres (cauliflower) were of almost uniform size, the shape microspheres (200°C) were almost the same as the all of other samples microspheres (cauliflower), but it differs in the size of the grains and crystallites, where the average grain sizes of CdS nanoparticles are about (27.11- 62.11) nm, individual particles sizes as show in the Fig. 2d. This indicates that there is an effect of temperature on the crystal size this effect was evident at 200 ° C, the results are in agreement with the literature [24, 25] which related to the shape and structure of the particle related to microspheres (cauliflower) and the reduction of the grains and particle size with the increase of the reaction temperature.

3.3. Antibacterial activity

The antibacterial activity of the prepared CdS nanoparticles was evaluated using the agar well diffusion method against the test cultures of gram +ve staphylococcus aureus, gram –ve Escherichia coli. The bactericidal effects of CdS nanoparticles were investigated against clinical isolates of staph.

and E. coli. Fig. 3; the presence of clear zones on the Muller Hinton agar surface proves that the CdS nanoparticles was able to inhibit the growth of E. coli and Staph. Four different nanoparticles concentrations (100, 250, 500, and 1000) (µg / ml) were taken to inhibit pathogenic bacterial growth as show in the table (2). The microbe-mediated CdS nanoparticles had the maximum zone of inhibition against disease-causing Staphylococcus and Escherichia coli about 19 mm at reaction temperature 180 oC and 30 mm at reaction temperature (160 and 180) ^{o}C respectively both at the highest concentration (100 µg/ml) of CdS nanoparticle. The minimum zone of inhibition was observed against staph. and E. Coli about 12 mm and 13 mm respectively at reaction temperature of 200 ^{o}C and concentration of CdS NPs. The area of inhibition was increases with the increased CdS NPs concentration and reaches the highest zone of inhibition at the highest CdS Nps concentration as shown in Figs 3 and 4 and all parameters and results were tabulated in Table 2.

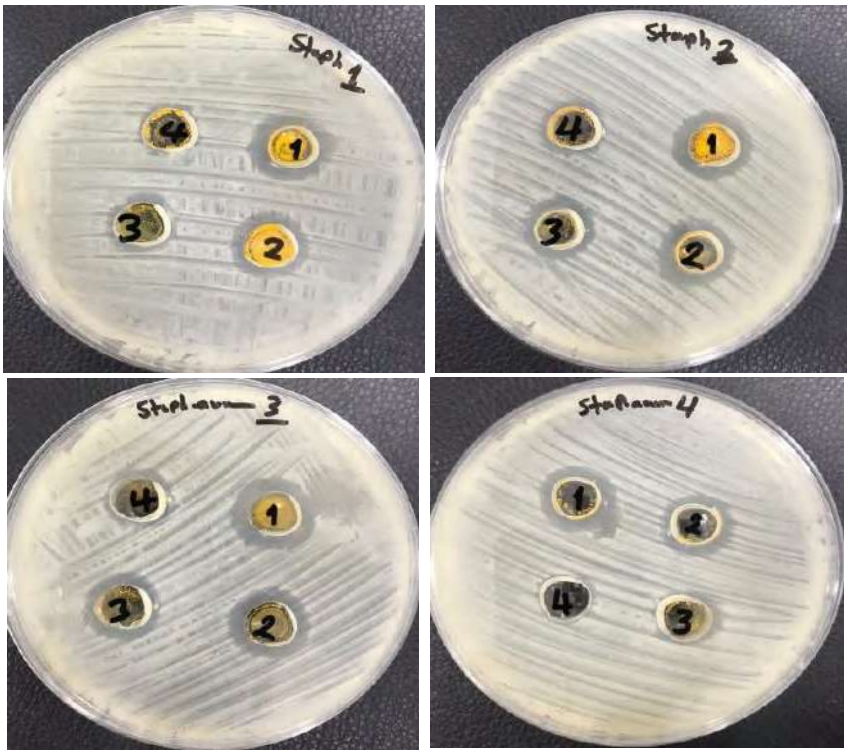

Fig.3. Antibacterial activity of CdS nanoparticles at different concentration (1, 2, 3, 4: 1000, 500, 250, 100) (µg/ml) against staphylococcus bacteria prepared at temperature (staph. 1, 2, 3, 4: 140, 160, 180, 200) °C respectively.

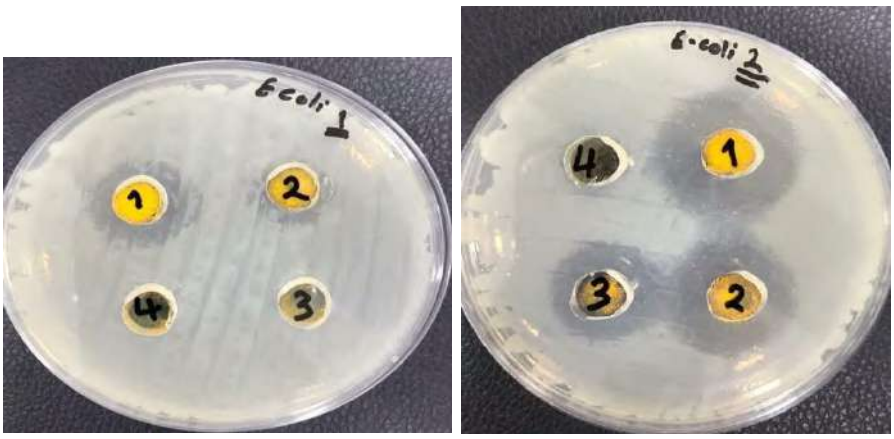

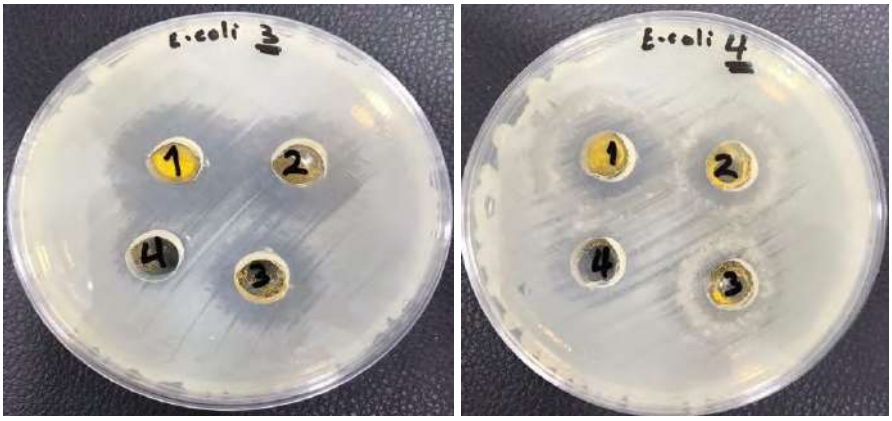

Fig.4. Antibacterial activity of CdS nanoparticles at different concentration (1, 2, 3, 4: 1000, 500, 250, 100) (µg/ml) against Escherichia coli bacteria prepared at temperature (E-coli 1, 2, 3, 4: 140, 160, 180, 200) °C respectively.

There are several mechanisms proposed for CdS NPs inhibitory action of the microbial growth. CdS NPs can cause DNA losses, impairment of its replication, and interfere with cellular proteins including ribosomal subunit proteins [27, 28]. Thus impairs the function of membrane-bound enzymes, in the aerobic strains. Also CdS get attached to the cell membrane and shrink the respiration of the bacterial cell which eventually causes the death of the cell as depicted [29, 30].

Table 2. Inhibition zone of CdS nanoparticles as antibacterial agents in millimeter (mm)

Types of used Bacteria	CdS Nanostructure prepare at temperature (^{o}C)	Concentration of CdS nanoparticle (µg/ml) / inhibition zone (mm)			
		1000 (1)	500 (2)	250 (3)	100 (4)
Staph.	140	17	16	15	13
	160	18	17	16	14
	180	19	18	17	14
	200	17	16	15	12
E-coli	140	23	15	-	-
	160	30	27	24	13
	180	30	25	23	16
	200	20	18	17	14

4. Conclusion

Briefly, CdS nanoparticle (cauliflower) of hexagonal phase has been successfully prepared by hydrothermal method at different reaction temperatures (140, 160, 180, 200 °C) for 4 hours. The crystal structure results indicate that the CdS crystal is of a high crystalline nature and hexagonal (wurtzite) phase. The average crystallite size was tended to increase with the increase of reaction temperature which about (21-24) nm. CdS nanoparticle micrographs images indicates rounded ball (cauliflower), the particles size were in the range of (23-245)nm and the smallest particle size was obtained at reaction temperature 200 °C. The antibacterial activity of cadmium sulfide CdS nanoparticles was estimated against two types of common bacteria (Escherichia coli and

Staphylococcus aureus). It was found that there is a strong antibacterial action and the greatest effect of them was for the prepared nanoparticles at reaction temperatures 160 and 180 ℃, and the highest activity was found against (E. coli) bacteria as well as with the increase of nanoparticles concentration. The antibacterial mechanisms of CdS NPs where the particles can anchor to the bacterial cell wall and infiltrate it and lead to damage the cell membrane and cellular content leakage. Also, CdS NPs can bind to the protein present in the cell membrane and lead to adenosine triphosphate (ATP) generation. As well as the NPs penetrate inside microbial cells, and then the nanoparticles and the released ions can interact with cellular structures and biomolecules such as proteins, enzymes, lipids, and DNA. It was established that synthesized CdS NPs with a higher antibacterial activity that was synthesized in different concentrations and reaction temperatures are potentially suitable for the development of nanomedicine and its applications.Also this work combines microbiology and nanotechnology, perform probable advances in the formulation of a new kind of antibacterial.

Abstract. This study investigates the effect of selection the electric pole radius of the four poles electrostatic doublets lens on the optical property. Also, a comparison between the optical property and performance of two lenses with different electrode radius was made. The results showed that the electric pole diameter of the lens plays main function in the imaging characteristics of the four poles electrostatic doublets lens. The results show that the aberration figures can be enhanced when the electrode diameter of the quadrupole lens is equal to the lens aperture, while the chromatic aberration can be improved by choosing the electrode diameter according to the equation.

Keywords: quadrupole lens, electrostatic quadrupole lens, SIMION.

1. Introduction

Quadrupole electrostatic lenses are used in a wide variety of applications, especially when imaging optical illusions not necessary [1, 2]. Due to the importance of electrostatic lenses in a large number of lenses applications, many researchers have studied this type of lens from different points of view (see [3, 4, 5, 6,7,8]). The particles accelerators, storage rings, mass analyzers, electron microscopes, and others are important instruments in the fields of scientific research and the electrostatic quadrupole lenses are used in these instruments because their ability on the control and focusing of the particles charged. Most of the theoretical bases of electrostatic and magnetic lenses were developed by pioneers and inventors of the electron microscope (Busch H 1927, Hawkes P 2004) [9-10].

Charged particle optics researchers can use facilities provided by some computer simulators to understand the fundamentals of charged particle optics and arrive at optimal designs for optical systems using optimal operating conditions [11, 12].

By reviewing previous articles in the field of the electrostatic quadrupole lenses, one can find two methods for choosing the radius of the electrodes of the quadrupole lenses according to the relation between this radius and the distance between the edges of the electrodes. In some articles, the diameter of the cylindrical electrode was taken equal to distance between the edges of the electrodes [13], while in other articles the diameter of the cylindrical electrodes is taken according to a certain equation dependence on the relation between the radius of electrode and the distance between the edges of the electrodes [14]. In the present work, the effects of choosing method to the electric pole radius on the optical property of the lens and its performance will studied and the comparison between two types of lenses will caried out.

2. Computational methods

In this research the lens electrode diameter was taken in two different Figure 1, the first case the lens diameter was taken to be equal to the distance between the egdes of electrodes or hole diameter (D) which is fixed to 20 mm, and in the second case the lens diameter was extracted from the relation r = 1.14511R R = D / 2 [14] and the diameter according to this equation is 8.73 mm, the electric pole length (L) 80 mm. The diameter of image (D) is 20 mm. The object (O) should be on the left part of the lens and the picture (I) on the right part of the lens. We will label the space between the subject and the reference plane (F) by (K) and the distance between the image and the reference plane by (G). The design is achieved using special virtual lab simulator in SIMION 8.1 of charged particles optics [15].

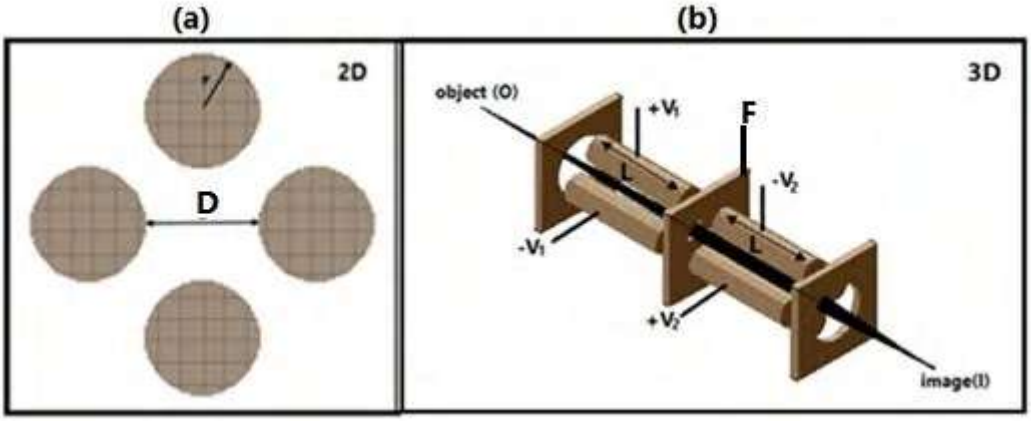

Figure 1. (a)(b) views one dimension and three dimensions of four poles electrostatic doublets lens.

One of the important steps in the design of the quadrupole lens is finding the applied voltages on the electrodes V1 and V2 lead to giving the image focus via focusing on both planes XY and XZ. To achieve this purpose, the code was written using the program language of LUA to find the voltage groups that give a spot image with the lowest point volume on the Position Sensitive Detector (PSD), where calculations were made for point-to-point focus.

3. Results and Discussion

The first step is to create an image of a spot in a four-pole electrostatic double lens is finding both voltage V1 and V2 which give the focus in two plane XY and XZ. Figure 2 shows the electrode voltages for two lenses with different electrode radius for focus point-to-point. The calculations have been carried out for fixed geometric dimensions K / D = 10, G / D = 10 (K is the space between the subject and the reference plane F, G: the space between the picture and the reference plane F, and D: the diameter of the hole); kinetic energy 1000 eV and the condition of the radius beam (r) at the screen is considered to be r = 0.01 mm at the first case and r = 0.001 mm at the second case.

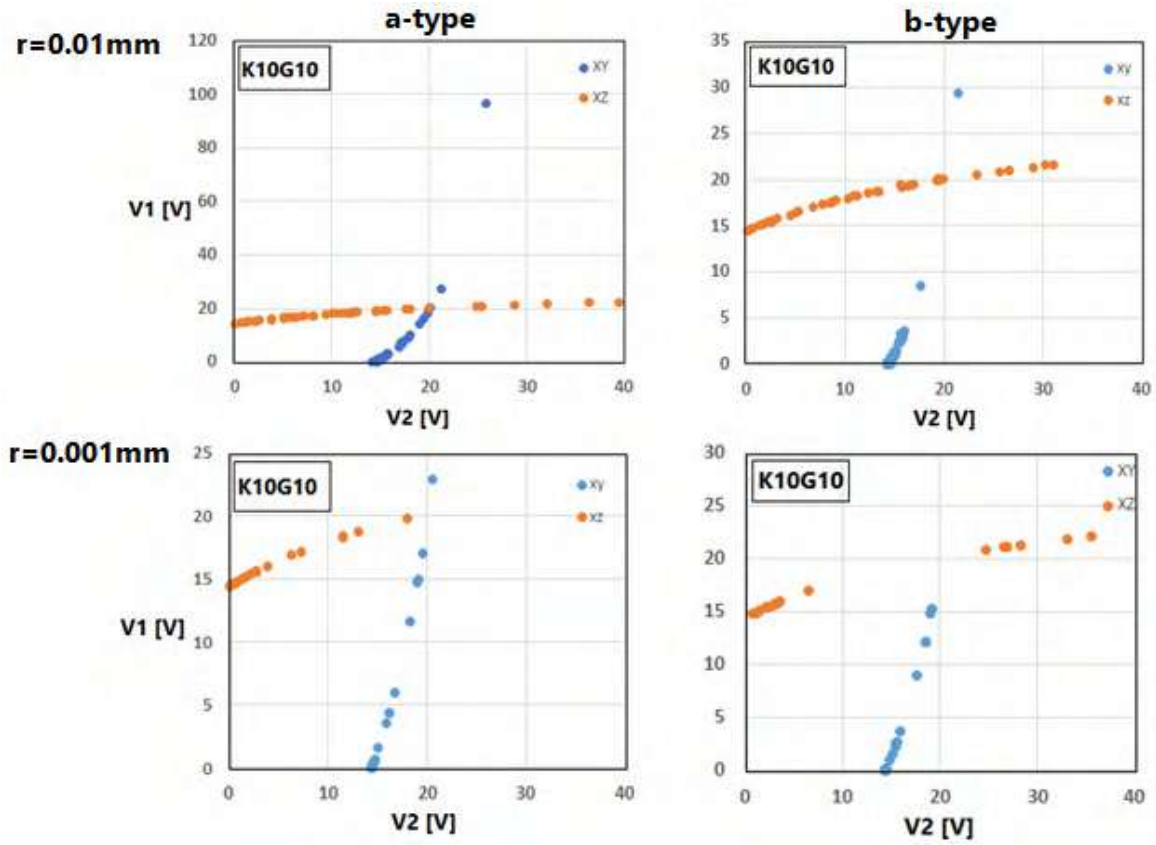

Figure 2. The voltage of two electrodes V_1 and V_2 for two lenses with different electrode radius at point-to-point focus mode (a) the diameter without using equation (b) the diameter using the equation r = 1.14511R, R = D / 2 [14], energy = 1000 eV, and angle α = 1◦ and for criteria of radius beam r = 0.01 mm and r= 0.001 mm. Here K10G10 stands for K / D = 10 and G / D = 10.

Figure 2 shows the relationship between V_1 and V_2, and there are two curves in these figures, for focus in the xy and xz planes. A point of intersection of two curves gives values of voltage that produce a point image or concentrate on the two planes simultaneously. In this figure obviously, the required voltage in the lens of type b is greater than that of type a when the beam radius r=0.01mm and, in the r=0.001mm the required voltage in a lens is greater than that for b lens. The equipotential surface distribution of the two four-poles electrostatic double lenses with two different electrode radius for K = G = 10D are shown in Fig. 3.

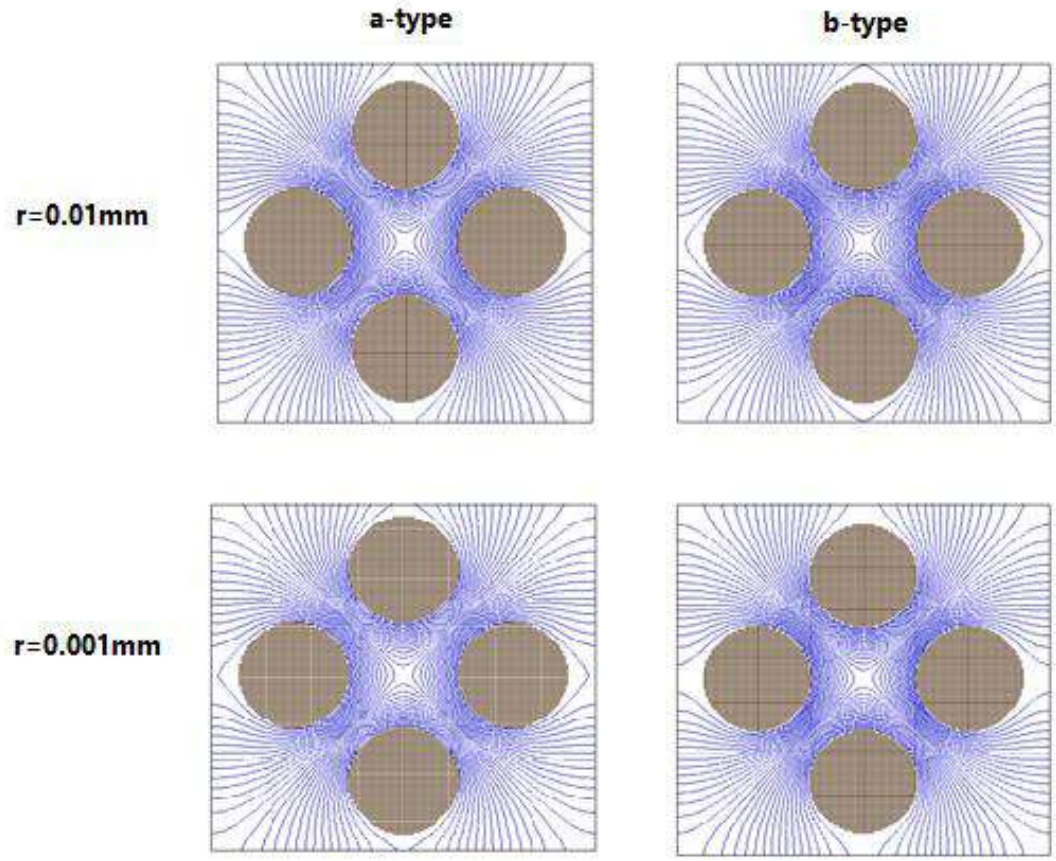

Figure 3. Equipotential surface distribution of the two four-poles electrostatic double lenses with two different electrode radius.

Figure 4 shows the electron beam paths in both the XY and XZ planes for point-to-point focus at K = G = 10 D. One can notice in this figure that the changing in the electrode radius of the lens leads to very small differences in the electron beam paths. These differences lead to important results in image levels as shown in Fig. 5. In this figure, the effect of the method of choosing the diameter of the electrode is appear clearly, especially when one search for very small dimensions image as is shown in figure 5 (b). The calculations show that the aberration is better when using electrode diameters exactly equal to the diameter of the lens aperture.

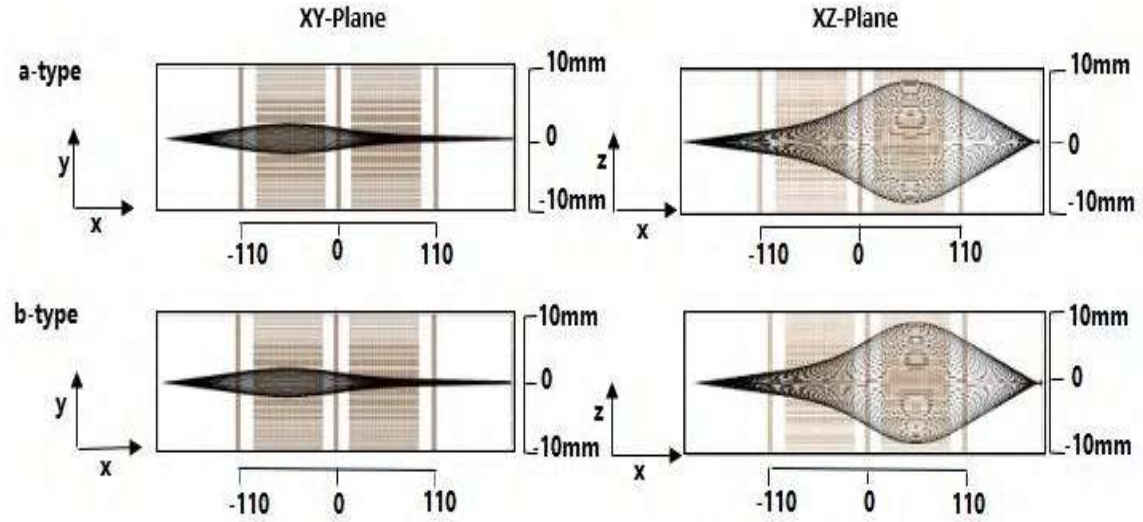

Figure 4. Shows the electron paths in the two planes for two different states of a four-poles electrostatic lens diameter for K = G = 10 D. (a) the diameter without using equation (b) the diameter using the relation r = 1.14511R, R = D / 2 [14]. The energy is 1000 eV, the beam radius r = 0.01mm for point-to-point focus with angle α = 1◦.

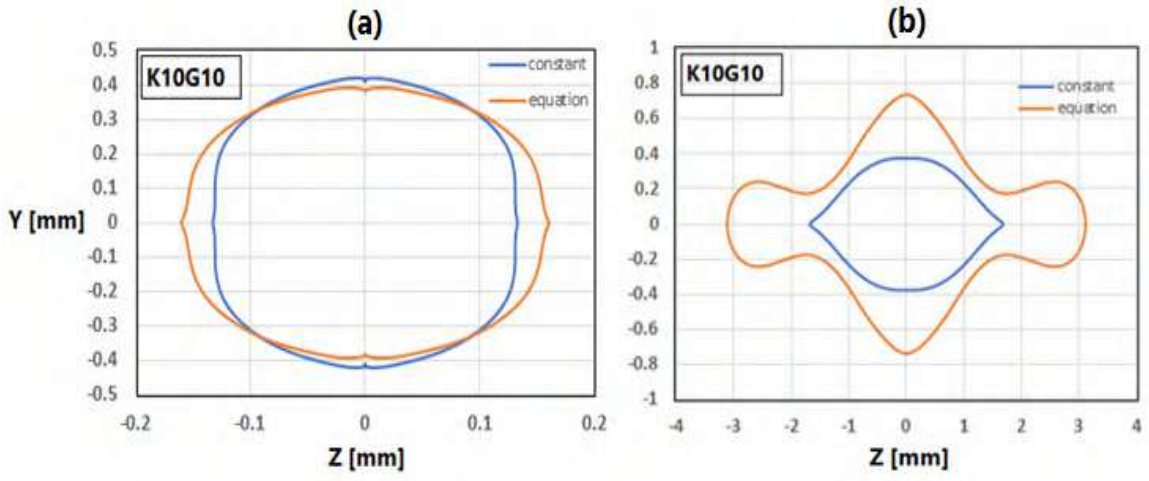

Figure 5. Comparison of the aberration shape for two different cases of quad-pole electrostatic lens diameter K = G = 10D, and the radius of the beam r with two different values (a) r = 0.01mm (b) r = 0.001mm. Here; P10Q10 means K / D = 10 and G / D = 10. Results are computed for angles α = 1◦.

The kinetic energy distribution of an electron beam is calculated for the lenses of two designs and the result is shown in Fig. 6. The results showed that the kinetic energy of an electron beams is more stable in the case of choosing the diameter of the electrode by using the equation. Therefore, the chromatic energy will be better in this case, because most of the electrons have the same kinetic energy. In general, for all cases the difference in the kinetic energy is very small and can be neglected.

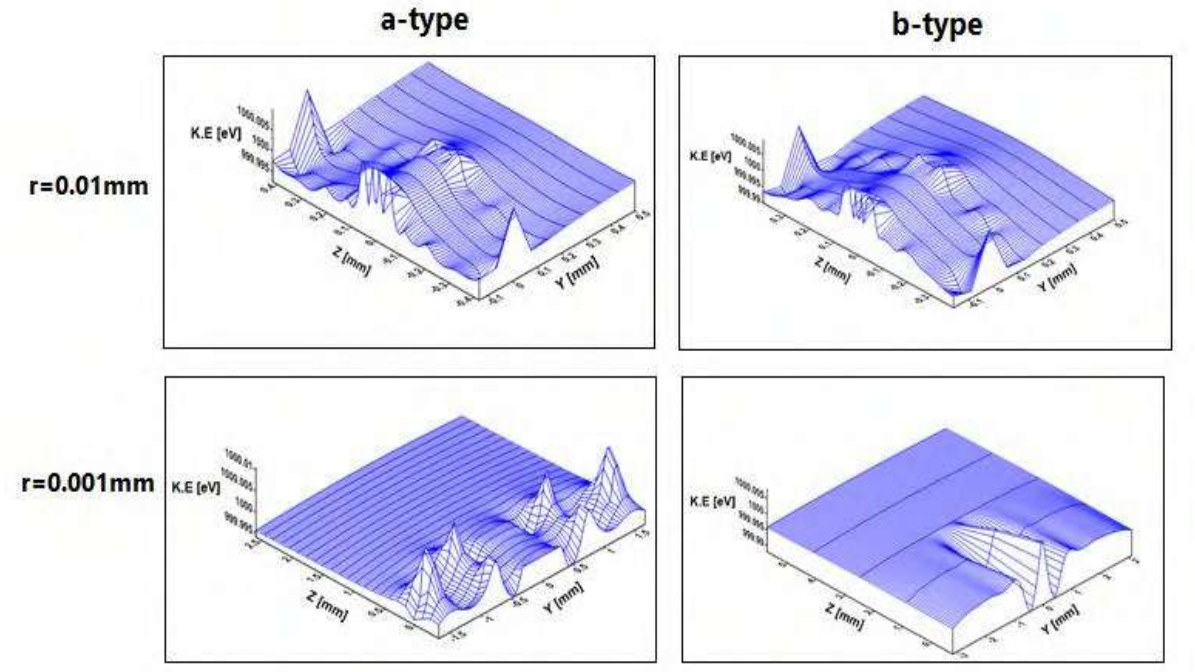

Figure 6. Distribution of the kinetic energy of an electron beam of two electrostatic four-poles double lenses with different electrode radius for K = G = 10D and beam radius r = 0.01mm, r=0.001mm.

Table 1 contains the comparison between some of the important parameters and operation conditions between the both designs of the electrostatic four-poles lenses with different diameters. The results in the table appear that the method of choosing the diameter of the electrode play a substantial role in determining the lens characteristic.

Table 1. The electrostatic four-poles double lens constants for the point-to-point operation mode with angle of an electron beam α = 1, the electron beam of two different values of the radius at the image plane r = 0.01 mm, r = 0.001 mm.

	r = 0.01 mm		r = 0.001 mm	
	(a)	(b)	(a)	(b)

G/D	10	10	10	10
$\Delta y(mm)$	0.82	0.76	0.74	1.46
$\Delta z(mm)$	0.26	0.31	3.34	6.2
Average time (µsec)	0.021415	0.0214149	0.0214144	0.021415

4. Conclusion

The imaging property of two types of electrostatic four-poles doublet lens systems were investigated. Calculations were made to focus point to point for two systems with different electrode radius of the lenses that is chosen using two methods of selection the electric-pole diameter of the electrostatic four-

poles lens depending on the relation between electrode radius and the lens aperture. The results showed that the method of choosing the dimeter of the electrode play substantial role in determining the lens characteristic and by choosing the appropriate method one can improve some of the properties. The results indicate that the aberration figures can be improved by taking the electrode radius equal to the radius of the aperture of the lens. Also, the results show that the electron beams kinetic energy is more stable in the case of choosing the diameter of the electrode by using the equation. Therefore, the chromatic energy will be better in this case, because most of the electrons have the same kinetic energy.

Characterization of carbon nanotube decorated silver nanoparticles

Characterization of carbon nanotube decorated silver nanoparticles

Taqwa Y. Yousif, Asama N. Naje

Baghdad University, college of science, physics department.

E-mail: Tyy3033@gmail.com

Abstract. Silver nanoparticles (Ag NPs) prepared using the exploding wire process has been decorated with carbon nanotubes (MWCNTs, SWCNTs). Well dispersion of silver NPs is achieved by a simple chemistry process on the surface of CNTs. The structure, optical and morphology of silver nanoparticles decorated with carbon nanotubes were characterized by x-ray diffraction, Atomic force microscopy, and field emission scanning electron microscopy. The illustrated outcome that the UV-Visible absorption and electrical conductivity properties effectively improved for CNT/ Ag NPs. The absorption spectrum of silver nanoparticles shows absorption at ultraviolet wavelength zone and there is low peak between (300-900nm) while the absorption of CNT/silver nanoparticles (Ag NPs) increased significantly from UV to near IR region. Field emission scanning electron microscopy analysis shows that silver nanoparticles are decorated on carbon nanotubes without any impurities, with average particle size about (50-80nm) for Ag-NPs, 44nm for MWCNTs/Ag-NPs and 30 nm for SWCNTs/Ag NPs . It was observed that Ag NPs enhanced the electrical conductivity of CNTs from (2.36 ×10-1 (1/ Ω.cm) to (1.03×10^4 (1/ Ω.cm)) for SWCNTs/Ag NPs and (8.83×10^4 (1/ Ω.cm)). It is observed that Ag NPs adding enhanced the electrical properties of CNTs. The results show that Ag-coated CNTs have important optoelectronic applications such as solar cell and photodetector.

Keywords: CNTs, Ag NPs, exploding wire method, optical Structure properties.

1. Introduction

Carbon nanotubes (CNT) have attracted significant research interest and they are widely used because of their excellent chemical, physical and electrical properties. Multi-walled carbon nanotubes (MWCNTs) and single-walled carbon nanotubes (SWCNTs) are considered ideal materials for different applications. [1, 2]. Metal nanoparticles (NPs) have gained a lot of interest in the fields of electronic, chemistry, and biology because, the high surface to volume ratio together with the size effect gives nanoparticles discriminative different properties (chemical, optical, electronic and magnetic) from those of bulk material[3, 4]. To synthesize metal nanoparticles, there are different techniques used such as a laser beam [5] ، electron beam, mechanical milling [6] ، electrical exploding wire [7] ، chemical vapor deposition [8] and electro-chemical method [9]. Decorating CNTs with metal nanoparticles provides new opportunities for researchers who have important applications in various fields, and is expected to exhibit different properties from individual CNTs [2]. Among the

different metal nanoparticles, Ag NP has been proven to have excellent property, making it suitable for different applications. CNT/Ag NPs has attracted great attention due to its importance in photodetectors [10, 1], gas sensor [11, 12], biosensor [13], etc.

Electrical explosion of wire method (EEW) is one of the vapor phase methods in which particles are produced by evaporating a thin metal wire by passing high current through it [14]. The phenomenon of electric explosion of wires (EEW) reduces to the following "When a high density (10^4–10^6 A/mm^2) current pulse, which is usually produced by the discharge of a capacitor bank, passes through a wire, the density of the energy in the wire may considerably exceed the binding energy because of a high rate of the energy injection and an expansion lag of the heated material. As a result, the material boils up in a burst, a bright light flashes, and a mixture of superheated vapor and boiling droplets of the exploding wire material and a shockwave scatter to the ambient atmosphere". In the other words the phenomena of (EEW) have been widely dependent on plasma physicists for generation and confinement of plasmas [15]. The properties of EEW synthesized nanoparticles depend on several parameters, including wire shape, such as wire (length and diameter) and material size, electrical circuit characteristics, and environmental media. There have been many experiments made to decorate CNTs with metal nanoparticles (Ag, Au) such as by Waleed K. Mahmood et al [16], and Ngo X. Dinh et al [17].

In the current work, we provide a simple system for the production of Ag NPs depended on the explosion of silver wire in distilled water, following this decoration of CNTs surface by Ag nanoparticles. The structural, morphological, and electrical properties of CNT-silver nanoparticles are studied using different characterization techniques.

2. Experimental Techniques

2.1 Synthesis of Ag-NPs by EEW

This work provides easy and effective devices for the processing of large numbers of metal nanoparticles for the wire explosion. In a reaction vessel of 500ml, the electro explosion of the wires (EEW) is accomplished to remain the two electrodes and the medium of the explosion. The wire goes and strikes the silver plate without bending in its way as Fig.1 shown, Teflon beaker was used to fix the two electrodes. The metal plate is passes through two groves on the surface of one block, while the wire was passes through a glass tube connected to the other block which placed opposite to the previous one. Both electrodes were joined to the two terminals of the 36V DC batteries by thick copper wires. The metal plates are fixed on the base of Teflon beaker filled with 30 ml of distilled water and just touching the first electrode through precise mechanical movement for 15 to hit, and then nominated by filtration paper. The silver nanoparticles will be stuck in the solution.

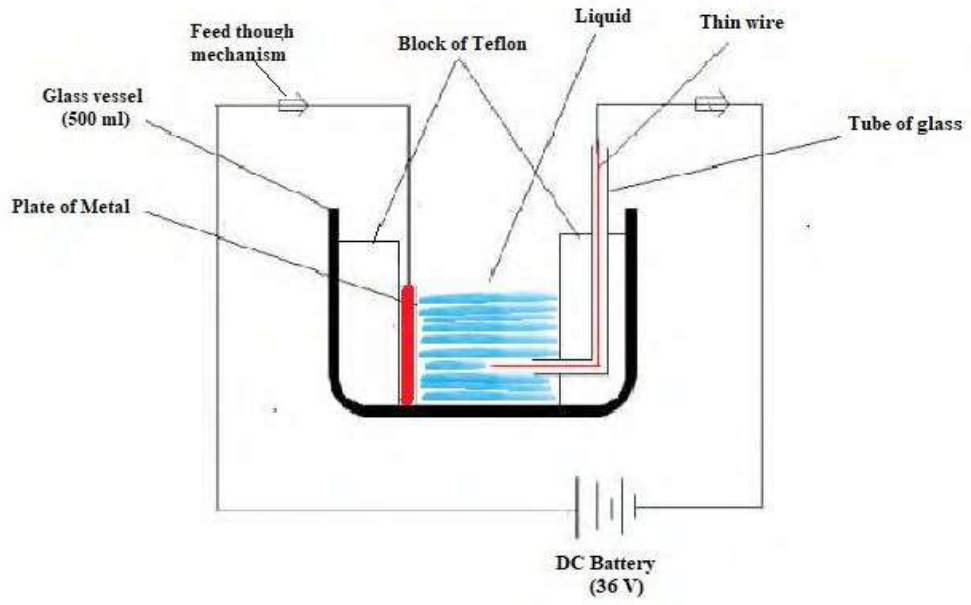

Fig. (1) A schematic diagram for Ag nanoparticles prepared by (EEW) set up.

The circuit remains disconnected until the wire mechanically touches the board. Due to the high current density through the wire, the wire explosion process occurs in a short period of time. This in turn opens the circuit for another explosion process. Silver wires of purity 99.99% , diameters of 1m length and plates (dimension : 2cm², 0.3mm; Purity: 99.99%) used in the explosion process.

2.2 Decoration of Ag NPs on Carbon Nanotubes (SWCNT & MWCNT)

The carbon nanotubes used in this work are multi-walled carbon nanotubes (MWCNTs) and single wall carbon nanotubes (SWCNTs)) supplied by Nanostructured & Amorphous Materials, Inc. The diameter of the MWCNTs range from 10-30 nm, length 1-2 μm and of 95% purity, and for SWCNTs range from 1-2 nm, length ~ 30 μm and of 90% purity. In the next step, the decoration of Ag-NP on CNT (SWCNT and MWCNT) was carried out. After forming silver nanoparticles, 10 ml of Ag-NPs was added with 0.05 g of SWCNT and MWCNT stirred for 12h and followed by 1 hour sonication.

3. Result and Discussion

3.1 UV-Visible spectroscopy

The UV-Visible absorption spectrum of the pure Ag NPs, SWCNT/Ag, and MWCNT/Ag prepared in water media are measured using Shimadzu UV-1800 spectrophotometer, all spectra are measured in a quartz cell at room temperature. The scanning range of CNT/Ag NPs absorption was (190-1000) nm using distilled water as a reference sample. Fig. 2 shows the UV-Visible absorption spectra as a function of wavelength.

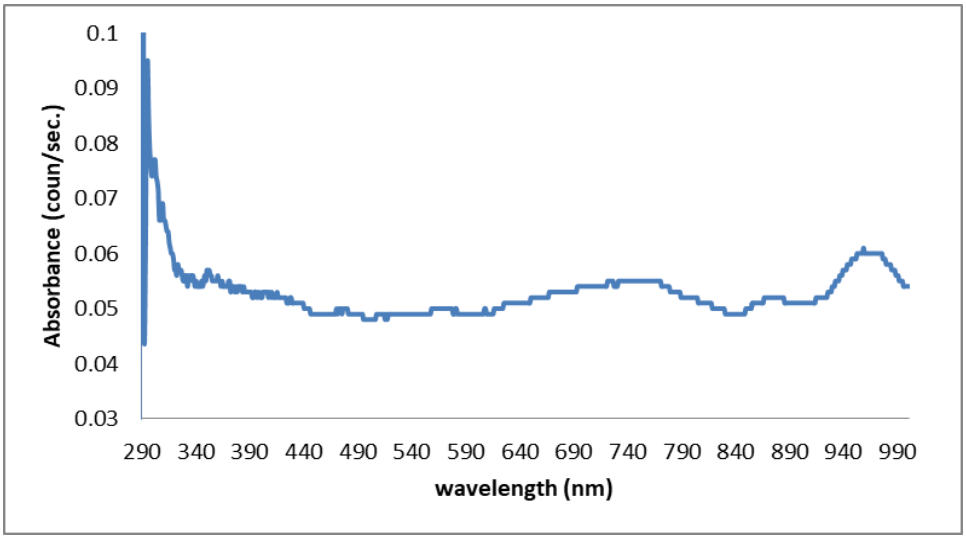

Fig. 2. UV-Vis light absorption spectra of Ag nanoparticle as a function of wavelength.

The UV-Vis spectrum observed that the Ag nanoparticles has fine structure absorption band in UV-Visible wavelength region of (~290 nm to 440 nm). The presence of narrow resonance absorption peaks is attributable to the excitation of surface plasmon vibrations in the silver nanoparticles; Surface Plasmon Resonance (SPR) band for Ag-NPs extended in the 450-510 nm range [18] with a peak position around 470 nm. A flat area was found in the phase at 300- 400 nm region, which indicates there is no absorption in this region or absorption is weak in this region.

According to Fig. 3 MWCNT/Ag and SWCNT/Ag NPs absorb light in the range of UV, Visible and NIR (300-1000 nm) but the (SPR) peak smaller than Ag-NPs because Proximity-induced charge transfer between (SWCNTs &MWCNTs) and silver could deplete the number of electrons available for surface Plasmon generation in the silver nanoparticles [18, 19].

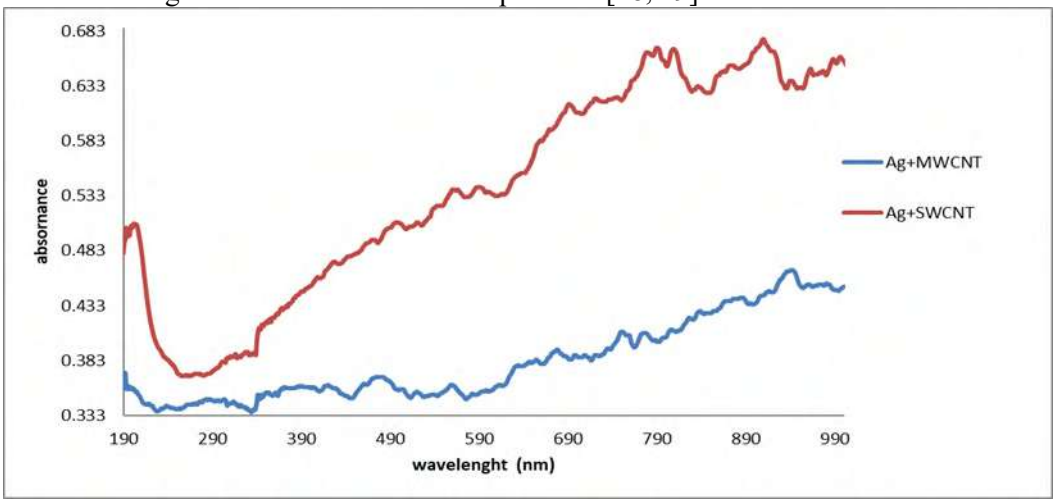

Fig. 3. UV-Vis light absorption spectrum of SWCNT/Ag & MWCNT/Ag as a function of wavelength.

3.2 Infrared Analysis spectroscopy FTIR

FTIR studies have been performed in the range 400 cm^{-1} to 4000 cm^{-1} for the identification of the functional group of the Ag NPs, MWCNTs/Ag NPs and SWCNTs/Ag NPs deposited on quartz

substrates. Fig. 4a, b and c show the FTIR spectrum for pure Ag NP, MWCNTs/Ag and SWCNTs/Ag NPs.

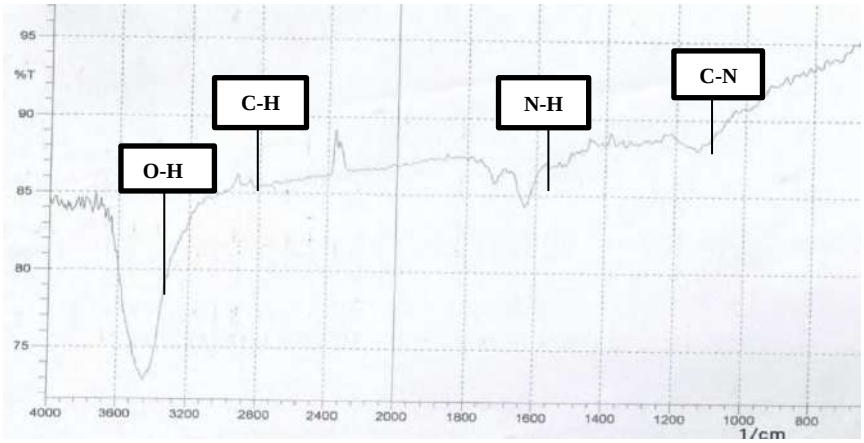

Fig. 4a. FTIR spectra for pure Ag NPs thin film.

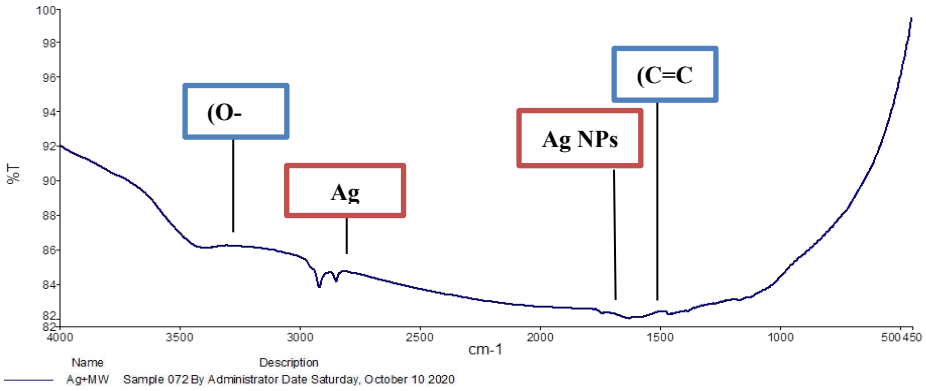

Fig. 4b. FTIR spectra for MWCNTs/Ag NPs thin film.

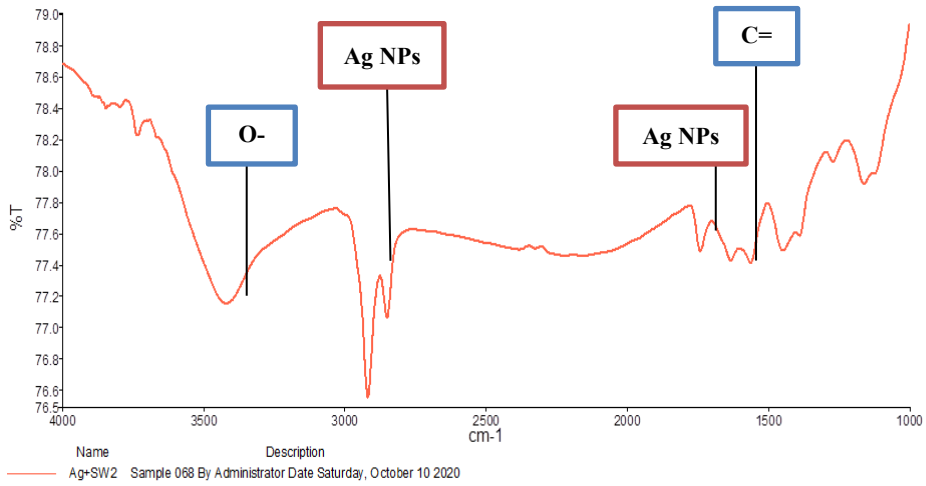

Fig. 4c. FTIR spectra for SWCNTs/Ag NPs thin film.

To determine possible interactions between the surface of silver nanoparticles and CNTs (SWCNT & MWCNT) molecules, the FTIR spectra of Ag nanoparticles were reported. By comparing the FTIR spectra of both silver nanoparticles and CNTs, it was found that in the FTIR spectrum of SWCNTs/Ag and MWCNTs/Ag, several peaks obtained by pure Ag-NPs were repeated with changes in location as well as in transmission band intensity. However, for the spectrum of the pure Ag-NPs, the

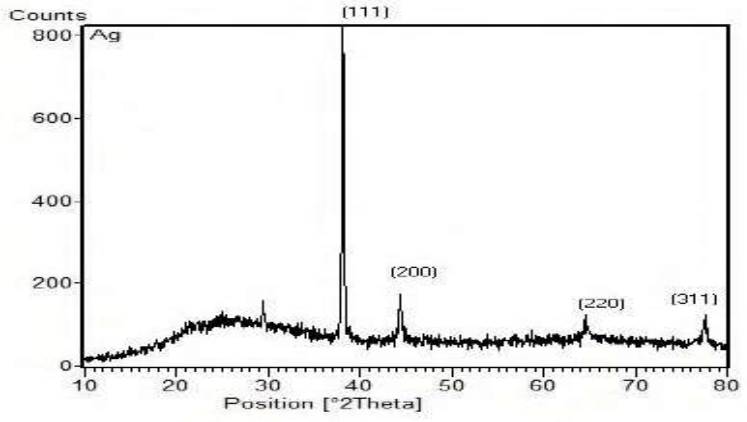
transmission band at (2968, 1720) cm-1 which can be assigned to the C-H symmetric stretching vibration is slightly shifted to (2926, 1752) cm-1, proving the interaction between the (SWCNTs and MWCNTs) molecules and Ag nanoparticles, and the broad peak appeared in the range of (3446, 3461 and 3500 cm-1) are attributed to O-H stretching vibration are in accordance with literature values [17, 20], the C=C bonding of aromatic rings of carbon skeleton structure were found at 1624cm-1.

3.3 X-Ray Diffraction Study

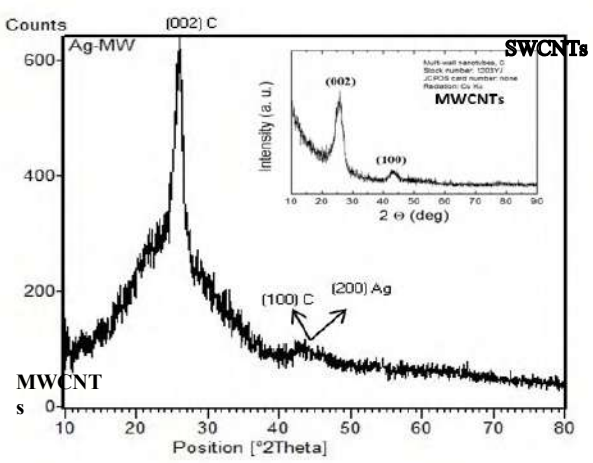
The X-Ray diffraction used to study crystalline structure of the Ag nanoparticles, SWCNTs/Ag and MWCNTs/Ag. This technique used (XRD -6000 labs, supplied by SHIMADZU, X-ray source are Cu Kα). The X-ray is used to determine the dimensional parameters for crystals and for the size estimation. For this purpose the following equation, known as the Scherrer equation is used [16]:

$$D = \frac{k\lambda}{\beta cos\theta} \quad \text{------- (1)}$$

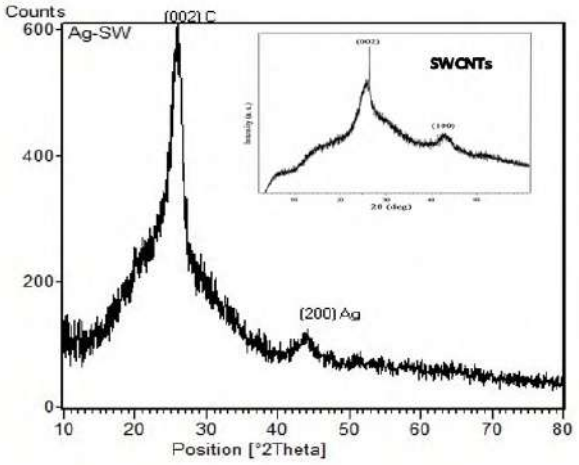
Where k is the shape factor, the dimensionless shape factor has typical value 0.9. D is the particle size. λ is the wavelength for X-ray source (X-ray source is Cu Kα with λ=1.5406Å). β is the full width at half maximum (FWHM) in rad. θ is the diffraction angle. The XRD patterns of silver nanoparticles, silver-MWCNTs, and silver-SWCNTs samples were displayed in Figure 5a, b and c.



(a)



(b)



(c)

Fig. 5. XRD patterns of (a) pure Ag Nanoparticles thin film, (b) MWCNTs/Ag NPs thin film and (c) SWCNT/Ag NPs thin film.

In Figure 5a, It can be shown that the pristine Ag-NPs sample exhibits a high (111) peak at 38.1˚, (200) peak at 44.3˚, (220) peak at 64.6˚ and (311) at 77.5˚ crystalline planes of metallic Ag indicate the Face-center Cubic (F.C.C) (JCPDS No. 04-0783). After the decoration of silver nanoparticles on CNTs, The Ag-MWCNTs XRD pattern reveals two obvious diffraction peaks. at 2 theta 26.2˚ which correspond to (002) for MWCNT and 44˚ match with both MWCNT (100) and Ag-NPs (200)[21] as shown in figure (5b). SWCNTs/Ag NPs composites, the diffraction pattern appeared at 2 theta of 26.2˚ for SWCNTs correspond to (002) and 44.1˚ for Ag-NPs correspond to (200)[16] as shown in figure (5c). These results compared with the standard JCPDS line given in table (3.1) with estimated the crystal size via the Scherrer formula Eq. (1).

Table 1. Crystal size of Ag-NPs, SWCNTs/Ag NPs and MWCNTs/Ag NPs as estimated via Scherrer formula.

Sample	**2Theta (degree)**	**cos θ**	**β (degree)**	**Avg. crystal size (D) nm**	**(hkl)**
Ag-NPs	38.1	0.94	0.19	0.58	(111)
	44.3	0.926	0.24		(200)
	64.5	0.84	0.29		(220)
	77.5	0.77	0.48		(311)
MWCNTs/Ag NPs	26.2	0.97	1.2	0.88	(002) CNTs
	44	0.927	0.09		(100) CNTs
					(200) Ag NPs
SWCNTs/Ag NPs	26.2	0.97	0.84	0.91	(100) CNTs
	44.1	0.926	0.09		(200) Ag NPs

3.4 Atomic Force Microscope (AFM)

The surface morphology and topography of the Ag NPs layer is shown in Fig. 6a, SWCNTs/Ag NPs layer in Fig. 6b and MWCNTs/Ag NPs in Figure 6c.

The prepared Ag NPs were analyzed using AFM. Picture shown in Fig. 6a is for the morphology of the Ag NPs, it seems that the Ag NPs had homogenous distribution with small cluster and the surface roughness was 9.807 nm, 11.7 nm height and average diameter 28.06 nm.

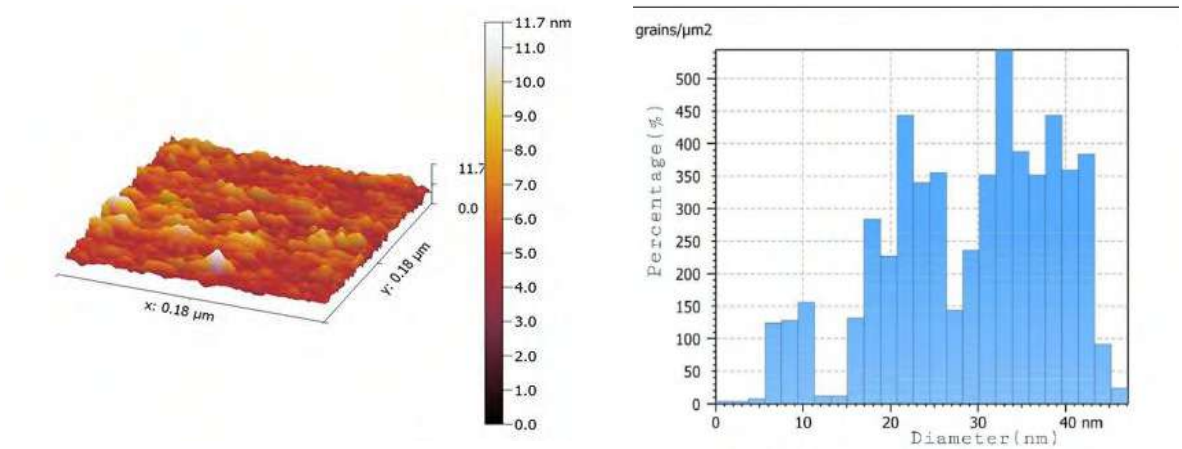


Fig. 6a. 3-D AFM image and distribution chart of pure Ag NPs thin film.

Fig. 6b displays the surface morphology and topography of the SWCNTs/Ag NPs layer observed from the micrograph of the AFM. It is noted that there was a normal distribution and homogeneous porous and 19.5 nm surface roughness, 19 nm height and average diameter was 58.14 nm.

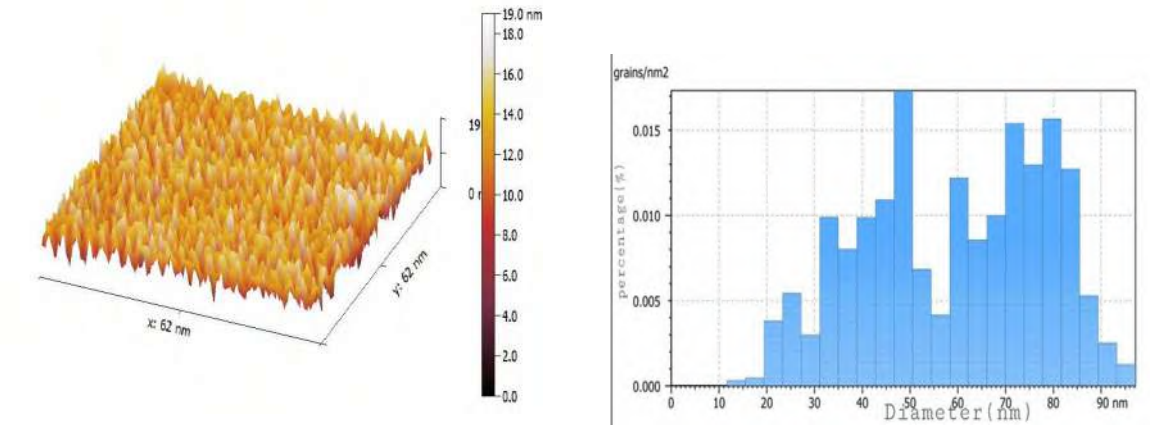

Fig. 6b. 3-D AFM image and distribution chart of SWCNTs/Ag NPs thin film.

The AFM of the MWCNTs/Ag NPs is shown in Fig. 6c the surface morphology of the MWCNTs/Ag NPs film had a good a uniform surface with regular distribution of the MWCNTs/Ag nanoparticles with the surface roughness was 39.5 nm, 22 nm height and average diameter 112.5 nm.

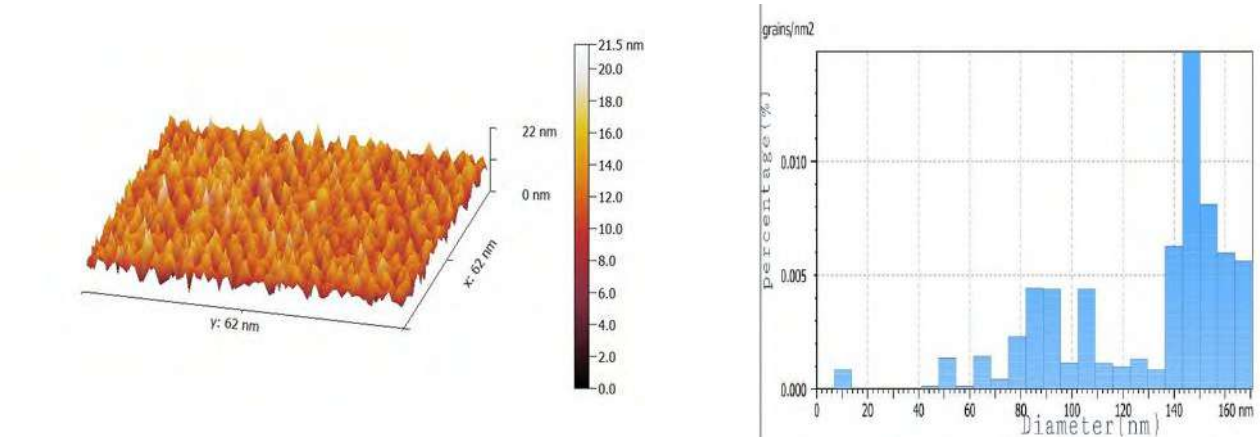

Fig. 6c. 3-D AFM image and distribution chart of MWCNTs/Ag NPs thin film.

3.5 Field Emission Scanning Electron Microscope (FESEM)

Scanning Electron Microscope images give the nanoparticles distribution, nanoparticles size, show shape and the structure of nanocrystal, mode FESEM from MIRA3 TESCAN, where high-resolution images of the surface of a sample is acquired. From Fig. 7a the FESEM shows spherical clustered and luminous spots (indicated by circles and in inset image) that correspond to silver nanoparticles, the average particle size of Ag NPS were ranging about (50-80nm).

These nanotubes were subsequently decorated with silver nanoparticles, Fig. 7 b, c show the FESEM of decoration Ag NPs on MWCNTs SWCNTs. The light spots on the CNT surfaces are the

silver nanoparticles. The image shows that the nanoparticles on the surface of the CNTs are fairly homogeneously distributed and the density of the attached nanocrystals is high.

Metal nanoparticles are easy to agglomerate, so that NPs are conjugated with CNTs to overcome these problems related to the stabilization, separation and recovery of NPs and prevent their aggregation [2].

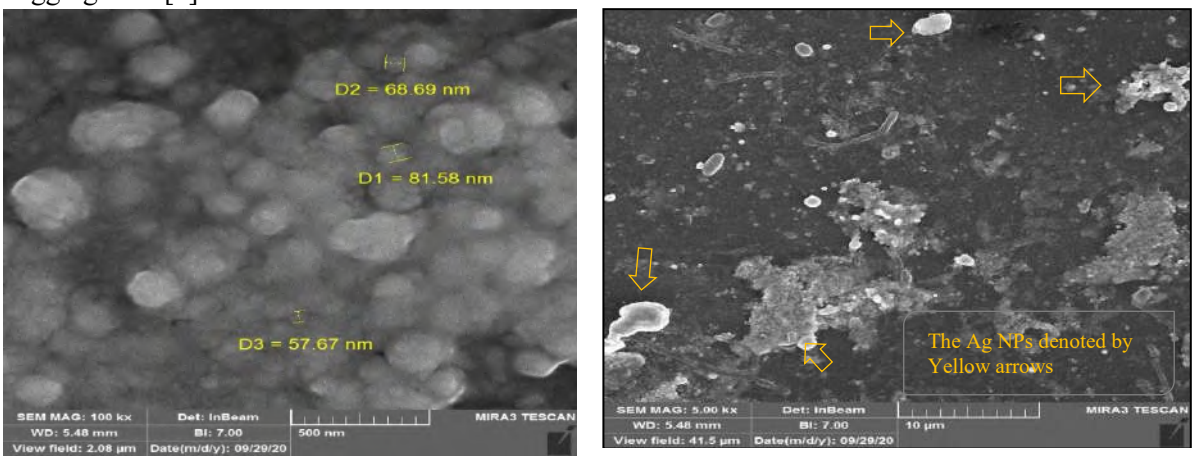

Fig. 7a. FESEM images of pure Ag NPs with different magnification (500 nm &10 µm).

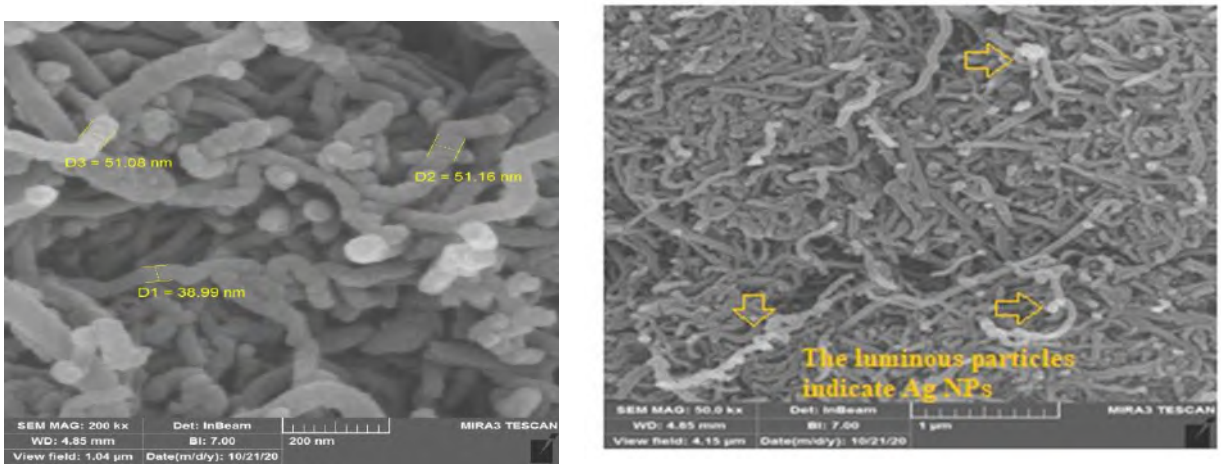

Fig. 7b. FESEM images of MWCNTs/Ag NPs with different magnification (200 nm & 1 µm).

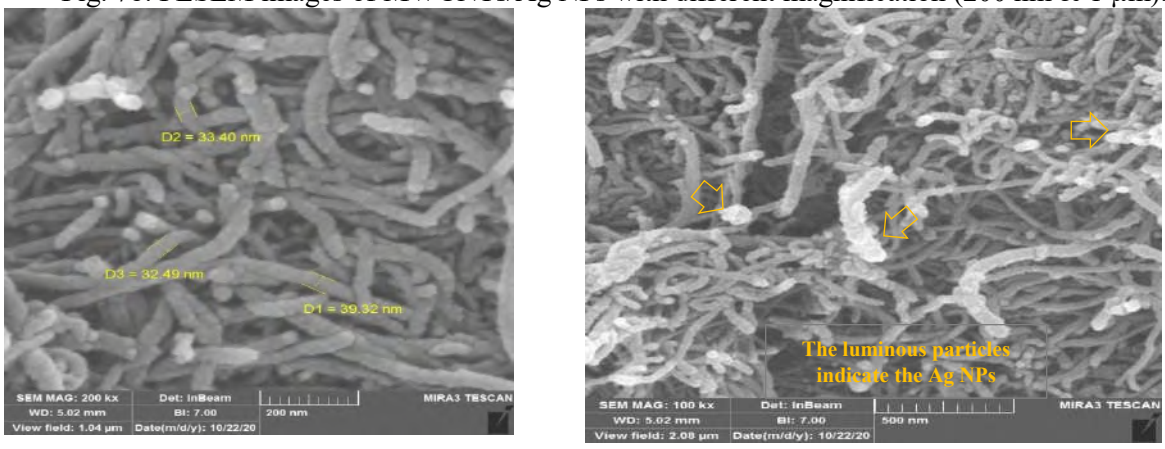

Fig. 7c. FESEM images of SWCNTs/Ag NPs with different magnification (200 nm & 500 nm).

3.6 Hall Effect Measurement

The Hall Effect was used to study the electrical properties of CNTs and Ag NPs (charge concentration, conductivity, carrier mobility, Hall coefficient and resistivity). Table 2 shows the Hall measurements parameter for CNTs and Ag NPs.

Table 2. Hall Measurement parameter.

Parameter	Ag NPs	SWCNTs/Ag NPs	MWCNTs/Ag NPs
Charge Concentration(1/cm^3)	$1.08*10^{13}$	$1.99*10^{22}$	$1.80*10^{22}$
Conductivity (1/ Ω.cm)	$2.36*10^{-1}$	$1.03*10^{4}$	$8.83*10^{4}$
Mobility (Cm^2/Vs)	$1.36*10^{5}$	3.22	$3.07*10^{1}$
Hall coefficient ($cm^{-3}.C^{-1}$)	$-5.78*10^{5}$	$3.14*10^{-4}$	3.4810^{-4}
Resistivity (Ω.cm)	4.23	$9.708*10^{-5}$	$1.132*10^{-5}$
Type	N-type	P-type	P-type

The table shows that electric conductivity CNTs/Ag NPs become much higher than Ag NPs and the concentration of carriers increase when CNTs decorated with Ag NPs, Also It can be seen that CNT decorated with Ag NPs converts from n-type to p-type when Ag NPs add to CNTs, which results in a shift in the Fermi energy from the valence band to mid-gap. The electrical transport of CNT/Ag NPs is improved when the CNTs decorated with Ag NPs.

4. Conclusions

The decoration of MWCNTs and SWCNTs with silver nanoparticles synthesized through exploding wire method was studied. Due to the simplicity of this synthesis, low-cost fabrication of large quantities of long-lived silver nanoparticles, the exploding wire method can be suggested to prepare the silver nanoparticles. It was found that the nanoparticles were spatially well dispersed on the carbon nanotubes. Integration of carbon nanotubes with AgNPs significantly improved CNTs optical absorption. CNT / Ag NPs absorb light in the range of 300-1000 nm better than CNTs alone, which demonstrates the special effects of noble metal on optical absorption of CNTs. The FTIR spectra proving the interaction between the (SWCNTs and MWCNTs) molecules and Ag nanoparticles. The FESEM image shows that the nanoparticles on the surface of the CNTs are fairly homogeneously distributed. It is suggested that decoration the CNT surface with AgNPs could change its characteristics of the materials from n-type to p-type. The experimental results have shown that the CNT/ Ag NPs can become important building blocks for nanoscale photodetector applications.

Abstract. In this paper, we investigate and study quantum theoretical of quark-gluon interaction modeling in QGP matter formatted. In theoretical modeling, we can use a flavor number, strength coupling, critical energy $T_c = 190$ MeV, system energy (400-650)MeV , fugacity of quark and gluon, and photon energy in range of 1-10 GeV parameter to calculation and investigation spectrum of photon rate. We calculation and study the photon rate produced through bremsstrahlung processes from the stable QGP matter. The photon rate production from $cg \rightarrow dg\gamma$ and $cg \rightarrow bg\gamma$ systems at bremsstrahlung processes are found to be increased with increased fugacity, decreased strength coupling, decreased the photons energy and temperature of system. The photons rate in $cg \rightarrow dg\gamma$ is increases a little compared to the $cg \rightarrow bg\gamma$ systems.

Keywords: Photonic Current Rate, Bremsstrahlung process.

1. Introduction

The elementary particle is considered as an one important field in physics because it uses a much more scientific method to study and investigate many facts to construction nature. Many theories introduced to study and understand the structure of nucleons and quark-gluon interaction formation the universal phase after the big bang stage [1] . Now ,there are different experimental results on hadron observable in collisions at the Relativistic Heavy Ion-Collision (RHIC) ,its showing that hadron must be produced in high energy collisions through quark–gluon plasma (QGP) formatted fireball [2]. The most important idea of heavy collisions is to study and create a strong interaction material; it obtains from the transformation of containment matter into (hadronic state) to a quark - gluon free. The quark - gluon interaction has found in the superfluid state form named quark-gluon plasma (QGP) and its produced in at Relativistic Heavy Ion-Collision (RHIC)[3]. The dynamics of quantum chromo dynamic media were discovered in the CERN Large Hadron Collider (LHC) and the Brookhaven National Laboratory in Relativistic Heavy Ionic Collider (RHIC) implies early equilibration of a quark-gluon system [4]. The quark-gluon plasma was existed for a short time ~several fm in volume~ 100 fm^3 and it can impossible detection the QGP state of matter directly. On the other hand, the different indirect signatures had been used to detect such as; strangeness enhancement, dilepton spectra, suppression and photon emission [5]. In fact, the theoretical approach to study and investigate

the elementary particles has been introduced by Standard Model; it's evolved in 1970's. The fundamentals of Standard Model are quantum chromodynamics and electroweak and theory [6]. The strength coupling is controlled on calculations of the photon production rate from a quark –gluon interaction in QCD medium and its possible limited only in certain situations. In weakly coupled quark with gluon indicate that the quark-gluon plasma (QGP) has a strength coupling smaller than one to complete estimation the photons rate [7]. Contrary to molecules and atoms, the quarks and gluons haven't found in freely, but were confined in hadronic state. This state was quite similar to decomposition of the magnetic pole north and south and never isolated each other [8]. The rate of photon emission from QGP matter is has estimation using phase-space distributed. They are assume to be Bose-Einstein and Fermi-Dirac distributions, while the lattice QCD estimation indicated that QGP system has been strong interaction ,for both non-ideal corrections taken into account the photon rate[9].

2. Theory

The number of photonic emitting rate production per unit time per unit volume via the usual QCD theory is [10].

$\Gamma_{qg}^{Br}(E,P) = -\frac{1}{(2\pi)^3}\mathrm{F}_B(\mathrm{E})\mathrm{Im}\prod_{qg}^{Br}(E,P)$……..(1)

Where $\mathrm{F}_B(\mathrm{E})$ is the distribution function of Bose-Einstein and $\mathrm{Im}\prod_{qg}^{Br}(E,P)$ is the imaginary part of the retarded self-energy polarization tensor of the photons at Bremsstrahlung processes. The distribution function of Bose-Einstein$\mathrm{F}_B(\mathrm{E})$ is given by [11].

$\mathrm{F}_B(\mathrm{E}) = \frac{1}{e^{E/T}-1}$……..(2)

Where E is the energy of photon and T is the heat energy of the system. Then the imaginary part $\mathrm{Im}\prod_{qg}^{Br}(E,P)$given by [12].

$\mathrm{Im}\prod_{qg}^{Br}(E,P) = (-1)\frac{NC_F}{\pi^4}e^2{g_{Br}}^2\frac{T}{E^2}|\mathrm{J}_{\mathrm{T}-L}|\int_0^\infty\left(\mathrm{F}_q(P)-\mathrm{F}_q(P+E)\right)(P^2+(P+E)^2)\,dP$…….(3)

Where N is an overall degeneracy factor , C_F is the Casimir operator of the system unitary group SU(N_c) , α is the quantum electrodynamics coupling, $\sum e_q^2$ is the square charge of quark ,${g_{Br}}^2$ is the square quantum chromodunamic coupling ,T is the heat energy of system ,E is the energy of photons ,$\mathrm{F}_q(P)$ is the fugacity of quark ,$\mathrm{J}_{\mathrm{T}-L}$ is the integral of the self-energy . The variance of constants self-energy is given by integral [13].

$\mathrm{J}_{\mathrm{T}-L} = \mathrm{J}_{\mathrm{T}} - \mathrm{J}_{\mathrm{L}}$…….(4)

J_{T}andJ_{L} are the dimensionless constants of the self-energy. Inserting Eq.(4) in Eq.(3), then imaginary part is reduce to .

$\mathrm{Im}\prod_{qg}^{Br}(E,P) = (-1)\frac{NC_F}{\pi^4}e^2{g_{Br}}^2\frac{T}{E^2}|\mathrm{J}_{\mathrm{T}}-\mathrm{J}_{\mathrm{L}}|\int_0^\infty\left(\mathrm{F}_q(P)-\mathrm{F}_q(P+E)\right)(P^2+(P+E)^2)\,dP$…….(5)

Introduce the electric charge of quarks $\sum e_q^2$ in Eq.(5) to given .

$\mathrm{Im}\prod_{qg}^{Br}(E,P) = (-1)\frac{NC_F}{\pi^4}e^2{g_{Br}}^2\frac{T}{E^2}|\mathrm{J}_{\mathrm{T}}-\mathrm{J}_{\mathrm{L}}|\sum e_q^2\int_0^\infty\left(\mathrm{F}_q(P)-\mathrm{F}_q(P+E)\right)(P^2+(P+E)^2)\,dP$…….(6)

The Juttner distribution function for quark$\mathrm{F}_q(P)$ and $\mathrm{F}_q(p+E)$ are given by [14].

$\mathrm{F}_q(P) = \frac{\lambda_q}{e^{\frac{(p)}{T}}+\lambda_q}$ …… .(7)

$\mathrm{F}_q(p+E) = \frac{\lambda_q}{e^{\frac{p+E}{T}}+\lambda_q}$……(8)

Where $\lambda_q$is the fugacity parameter. Inserting Eqs.(7) and (8) in Eq.(6) and simply to reduced .$\mathrm{Im}\prod_{qg}^{Br}(E,P) =$

$$(-1)\frac{NC_F}{\pi^4}e^2{g_{Br}}^2\frac{T}{E^2}|\mathrm{J_T}-\mathrm{J_L}|\sum e_q^2\times\left[\int_0^\infty\frac{\lambda_q\left(2P^2+2PE+E^2\right)}{e^{\frac{(p)}{T}}+\lambda_q}dP-\right.$$

$$\left.\int_0^\infty\frac{\lambda_q\left(2P^2+2PE+E^2\right)}{e^{\frac{p+E}{T}}+\lambda_q}dP\right]\text{.....(9)}$$

The solve of the integral term give results

$$\left[\int_0^\infty\frac{\lambda_q\left(2P^2+2PE+E^2\right)}{e^{\frac{(p)}{T}}+\lambda_q}dP-\int_0^\infty\frac{\lambda_q\left(2P^2+2PE+E^2\right)}{e^{\frac{p+E}{T}}+\lambda_q}dP\right]=\Lambda\left(\lambda_q,E,T\right)=\left[2T^3\Gamma(3)+2\mathrm{E}T^2\Gamma(2)+\right.$$

$$E^2T\Gamma(1)\left][\frac{{\lambda_q}^1}{1^3}\left(1+e^{\frac{-E}{T}}\right)-\frac{{\lambda_q}^2}{2^3}(1+e^{\frac{-2E}{T}})+\frac{{\lambda_q}^3}{3^3}(1+e^{\frac{-3E}{T}})-\frac{{\lambda_q}^4}{4^3}(1+e^{\frac{-4E}{T}})+\frac{{\lambda_q}^5}{5^3}(1+e^{\frac{-5E}{T}})-\right.$$

$$\cdots\frac{{\lambda_q}^n}{n^3}(1+e^{\frac{-nE}{T}})\text{....(10)}$$

Inserting Eq.(10) in Eq.(9) to obtain .

$$\mathrm{Im}\prod_{qg}^{Br}(E,P)=(-1)\frac{NC_F}{\pi^4}e^2{g_{Br}}^2\frac{T}{E^2}|\mathrm{J_T}-\mathrm{J_L}|\sum e_q^2\,\Lambda\left(\lambda_q,E,T\right)\text{.....(11)}$$

The coupling parameter for QCD theory is given by [15].

$$\alpha_1^{sc}=\frac{{\mathrm{g_{Br}}}^2}{4\pi}\text{.....(12)}$$

Where $\mathrm{g_{Br}}$ is the constant of strong coupling interaction.The Casimir operator C_F is corresponded to representation of color charge is [16].

$$\boldsymbol{C_F}=\frac{(\boldsymbol{N_c^2-1})}{\boldsymbol{2N_c}}\qquad\text{...}\text{.....(13)}$$

where N_c is the color number constant.

Inserting Eq.(12) and Eq.(13) in Eq.(11) to obtain .

$$\mathrm{Im}\prod_{qg}^{Br}(E,P)=(-1)\frac{N}{\pi^3}\frac{\mathbf{16}}{\mathbf{3}}e^2\alpha_1^{sc}\sum e_q^2\,|\mathrm{J_T}-\mathrm{J_L}|\frac{T}{E^2}\Lambda\left(\lambda_q,E,T\right)\text{.... (14)}$$

The quantum electrodynamics QED coupling constant [17].

$$\alpha=\frac{e^2}{4\pi}\text{ ..... (15)}$$

substituting Eq.(**15**) in Eq.(**14**) to obtain .

$$\mathrm{Im}\prod_{qg}^{Br}(E,P)=(-1)4\frac{N}{\pi^2}\frac{\mathbf{16}}{\mathbf{3}}\boldsymbol{\alpha}\alpha_1^{sc}\sum e_q^2\,|\mathrm{J_T}-\mathrm{J_L}|\frac{T}{E^2}\Lambda\left(\lambda_q,E,T\right)\text{.... (16)}$$

Inserting Eq.(16) in Eq.(1) to obtain.

$$\Gamma_{qg}^{Br}(E,P)=\frac{N}{\pi^5}\frac{\mathbf{8}}{\mathbf{3}}\boldsymbol{\alpha}\alpha_1^{sc}\sum e_q^2\,|\mathrm{J_T}-\mathrm{J_L}|\frac{T}{E^2}\mathrm{F}_B(\mathrm{E})\Lambda\left(\lambda_q,E,T\right)\text{.... (17)}$$

The overall degeneracy factor N in QCD theory is equal to quantum number of color $N_c=3$, then Eq.(17) becomes.

$$\Gamma_{qg}^{Br}(E,P)=\frac{\mathbf{8}}{\pi^5}\boldsymbol{\alpha}\alpha_1^{sc}\sum e_q^2\,|\mathrm{J_T}-\mathrm{J_L}|\frac{T}{E^2}\mathrm{F}_B(\mathrm{E})\Lambda\left(\lambda_q,E,T\right)\text{.... (18)}$$

The Bosonic function distribution for gluon $\mathrm{F}_B(\mathrm{P})$ [18] and simply to .

$$\mathrm{F}_B(\mathrm{E})=\frac{\lambda_g}{e^{\frac{E}{T}}-\lambda_g}=\frac{1}{\frac{E}{e^{\frac{E}{T}}}-1}\approx\lambda_g e^{\frac{-E}{T}}\text{.....(19)}$$

The Eq.(18) becomes with Eq.(19) is.

$$\Gamma_{qg}^{Br}(E,P)=\frac{\mathbf{8}}{\pi^5}\boldsymbol{\alpha}\alpha_1^{sc}\sum e_q^2\,|\mathrm{J_T}-\mathrm{J_L}|\frac{T}{E^2}\lambda_g e^{\frac{-E}{T}}\Lambda\left(\lambda_q,E,T\right)\text{.... (20)}$$

The strength coupling constant is given by [19].

$$\alpha_1^{sc}=\frac{6\pi}{(33-2n_F)ln(\frac{\mu_1}{\mu_0})}\text{.....(21)}$$

where μ_1 is the momentum or heat energy and $\mu_1\approx 8T$ and μ_0 is refers to heat energy or momentum in hadrons phase $\mu_0\approx T_{cr}$,whereT_{cr} is the critical temperature .

3. Results

To obtain the spectrum of photons rate at bremsstrahlung process depend on the quantum chromodynamic QCD theory one can be calculate the strength coupling through estimation the flavor number .The estimation of flavor number included in estimating the summed on total flavor number $N_f = \sum_{n=1}^{6} N_{fn}$ using Table 1 for system species, the system $cg \to dg\gamma$ in being the number flavor $n_f = 6$of chram quark (n_f =4) and down quark (n_f =2) and the system $cg \to bg\gamma$in being the number flavor $n_f = 9$of chram quark (n_f =4) and bottom (n_f =5) in the system.

Table 1. The main properties of quarks [20].

Fermions	Name	Mass	Electric Charge	N_f
Quarks	Up (u)	$2.3^{+0.7}_{-0.5}\,MeV/c^2$	$+{}^{2}/_{3}\ e$	1
	Down (d)	$4.8^{+0.5}_{-0.3}\,MeV/c^2$	$-{}^{1}/_{3}\ e$	2
	Strange (s)	$95 \pm 5\,MeV/c^2$	$-{}^{1}/_{3}\ e$	3
	Charm (c)	$1.275 \pm 0.025\,GeV/c^2$	$+{}^{2}/_{3}\ e$	4
	Bottom (b)	$4.18 \pm 0.03\,GeV/c^2$	$-{}^{1}/_{3}\ e$	5
	Top (t)	$173.2 \pm 0.9\,GeV/c^2$	$+{}^{2}/_{3}\ e$	6

In order to calculate the photons rate , we can evaluated the strength coupling ,total charge and total flavor number . For the strength coupling calculation for quarks-gluon interaction at bremsstrahlung , the photons are yielding at temperature around (400,450,500,550,600 and 650 MeV) are necessary. The strength coupling can be calculated using Eq.(21) and so one can use summation of the flavor number $n_f = (4 + 2) = 6$ for $cg \to dg\gamma$and $n_f = (4 + 5) = 9$ for $cg \to bg\gamma$ system with the critical temperature $T_c = 190$ and the temperatures of system in the range (400 to650 MeV),results are shown in table (2) for $cg \to dg\gamma$and $cg \to bg\gamma$ systems respectively.

Table 2. Results of strength coupling for $cg \to dg\gamma$and $cg \to bg\gamma$ systems using the critical temperature$T_c = 190$.

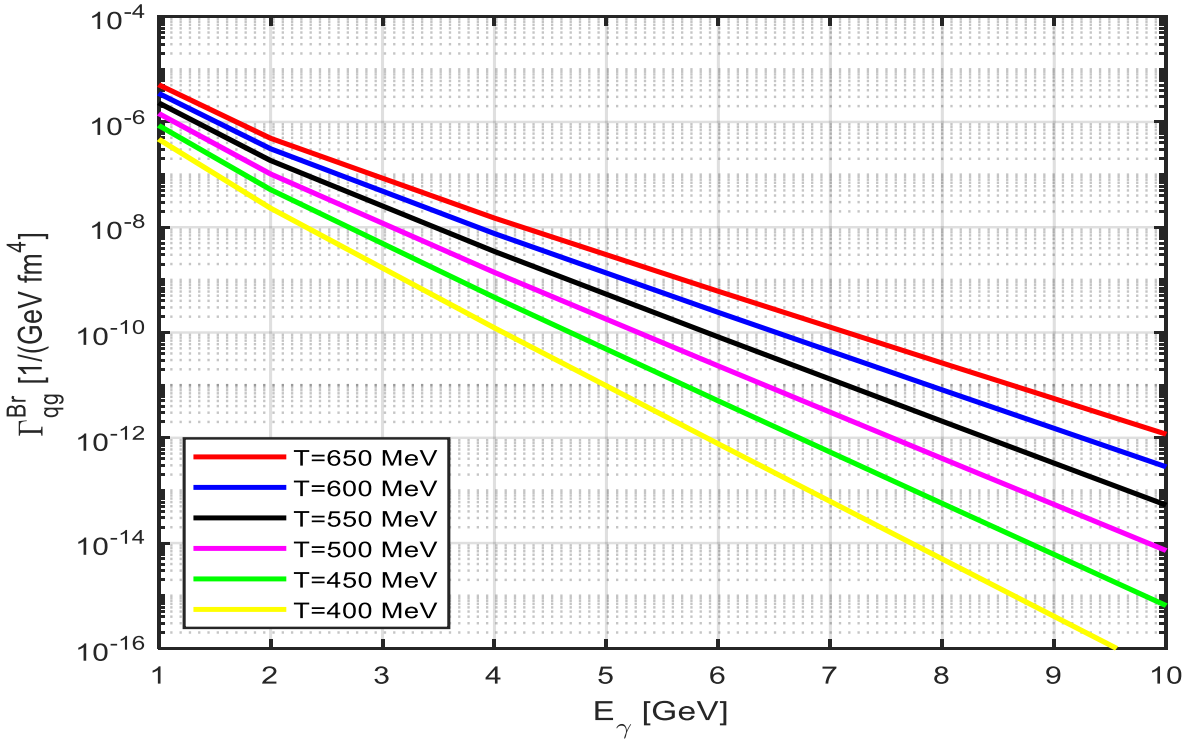

Figure 2. Rate of photon production $\Gamma^{Br}_{qg}(E,p)$ as a function of E_γ for $cg \to bg\gamma$ system at $T_c = 190\ MeV$.

To compute the net electric charge for $cg \to dg\gamma$ and $cg \to bg\gamma$ systems at the bremsstrahlung processes can be estimated using the summation of all charges for quarks in the system and be deduced using the $\sum_i^n e_{qi}^2 = (\frac{2}{3})^2 + (\frac{-1}{3})^2 = {}^5/_9$ for both systems. However, the photons rate calculated with the same parameters except fugacity that taken $\lambda_q = 0.02$ [13] and $\lambda_g = 0.08$[13], results are shown in Table 5 and Figure 3 for $cg \to dg\gamma$ system and Table 6 and Figure 4 for system.

Table 5. Rate of photon production $\Gamma^{Br}_{qg}(E,p)$ at $T_c = 190\ MeV$ with $\lambda_q = 0.02$, $\lambda_g = 0.08$ in system $cg \to dg\gamma$ has flavor number $n_f = 6$ in Bremishtahlang process.

4. Discussion

Due to quantum chromo dynamic theory, we present the theoretical results for the calculation the photon rate of photon production from bremsstrahlung at the different photon energy (1-10) GeV at critical temperature 90MeV with the different fugacity for quark and gluon. The calculation has been done for two different $cg \rightarrow dg\gamma$and $cg \rightarrow bg\gamma$quarks systems have total flavor number 6 and 9. From Table 2, it can be shown that running strength coupling α_1^{sc} decrees with increase the temperature of quark gluon system for both $cg \rightarrow dg\gamma$and $cg \rightarrow bg\gamma$ systems ,this because the confinement and asymptomatic behavior of quarks with concerning the fact or slow photons rate, the results show the photons rate increased with decreased the strength coupling and vice versa. Furthermore, the behavour of the strength coupling of $cg \rightarrow bg\gamma$ system is larger than the strength coupling of $cg \rightarrow dg\gamma$system because to effect of flavor number for the same critical energy and temperature of the system . To each system , the strength coupling α_1^{sc} and the photon rate spectrum of the emitted bremsstrahlung is calculated in photons energies$E_\gamma\ GeV$ ranging (1-10GeV) .The total photons rate of the bremsstrahlung emission has been obtained due to integrating the Eq.(9) on the photon momentum determined previously. For each photon energy and temperature of the system, the number of photons emission from bremsstrahlung is obtained by using Eq.(20). Briefly, the photon rate from bremsstrahlung are slowing down with increased energy of photons and the photons will be attenuatied in the QGP mater .As for the $cg \rightarrow dg\gamma$ system , the photon spectrum emitted in bremsstrahlung at energy $E_\gamma = 1GeV$ is faster compare with $E_\gamma = 10GeV$,this indicate for energy $E_\gamma = 10\ GeV$ the system emission photons by small rate . On the other hand, the emitted photons by bremsstrahlung with fugacity $\lambda_q = 0.02$, $\lambda_g = 0.08$ are lower than $\lambda_g = 1$ and $\lambda_q = 0.068$, that's means when increased fugacity lead to emission more photons for both systems. Consequently, the fugacity hasn't yet e much by effected on increasing, but the strength and flavor number can induce more photons to emit the higher energy bremsstrahlung. In conclusion ,the fugacity intense to the

photons spectrum obtained in bremsstrahlung process, this calculation will be supply more knowledge about reaction of quark and gluon to conceive the nature of shielding of the source In the this work, the bremsstrahlung emissions of $cg \rightarrow dg\gamma$and $cg \rightarrow bg\gamma$ systems are increased with decreasing strength coupling for photons energies in the interval 1-10 GeV. In Figures 1 to 4, the spectra of photons rate $\Gamma_{qg}^{Br}(E,P)$of the bremsstrahlung emerging by photon energy are represented in Tables (4-7). As expected, the photon emission rate of the bremsstrahlung at high-energy yield in small region of system around the QGP matter. Generally , , the photons emission rate values of the bremsstrahlung increased with increased fugacity and increased flavor and decreased strength coupling of then system . However, larger photons rate appear in the high-energy region, where $E_\gamma < 10\,GeV$ and reach a maximum at the energy of the photons $E_\gamma = 1\,GeV$. These differences indicate that the cross-section of reaction in $E_\gamma = 1\,GeV$ can be probable compare cross section in $E_\gamma = 10\,GeV$ in the high energy region (1-10)GeV .In all Figures (1-4) , the plotted forphotons rate are given same behavior with range high energy(1-10)GeV but the photons yield rate in Figure 3 and (4) with fugacity $\lambda_q = 0.02$, $\lambda_g = 0.08$are lowered than at Figures 1 and 2 with fugacity $\lambda_g = 1$ and $\lambda_q = 0.068$ by a factor $\sim 10^2$.

5. Conclusion

In concluding that the calculation of the photon rate through the bremsstrahlung process enhanced by flavor number, strength coupling fugacity, photon energy and temperature of the QGP mater system and give stability feature in quark –gluon system formation. The overall evaluation of photon emission rate production through the bremsstrahlung process and the spectra as a function of strength coupling and photon energy incorporate to give the results of photon yield rate. The photon rate for the bremsstrahlung has been increased with increased fugacity and increased flavor and decreased strength coupling of the system. Thus, the consideration of the quntum chromodynamic theory in the quark – gluon is the important role in the calculation of photon rate at the high energy. So, this theoretical model can be supply results to improve the other theoretical and experimental results.

The effective of the inner radius of the iron free coil on the paraxial ray for magnetic lenses

The effective of the inner radius of the iron free coil on the paraxial ray for magnetic lenses

Ahmed K. Al-kadumi[1] and M. Al-Baghdadi[1]

E-mail: muhammid.h@uokerbala.edu.iq

Abstract. In this paper, the magnetic flux density was studied using a mathematical model and different inner radius has been used for the iron free coil. The maximum value of magnetic field and the magnetic scalar potential was calculated. The paraxial ray can be studied using rung Kutta to solve the differential equation in the infinite and zero magnification condition, all results are determined using MATLAB program.

Keywords: electron optics, ions optics, iron free magnetic lenses, the potential of the electron lenses, electron microscopy

1. Introduction:

Electron optics is image formation by means of Deblorgle principle which can change the resolution by changing some parameters as electrons potential or the excitation of the lens[1, 2].The magnetic field can be stimulated using a mathematical model which has parameters and change the foundation of the lens [2, 3]. The effect of the geometry parameters on the results, the beam throw and emerge beams are studied[4].

There are many mathematical models which represent the magnetic field, and many models can represent the magnetic scalar potential. Using the inverse design procedure and the optimization to receive the optimal lenses, the non-dominated sorting genetic algorithm (2) and the electron optics simulations were combined and make a multi-objective optimization design tool for electron optics. To determine the function of the objective that varies with the parameters of the macroscopic electrical to need that optimize the electron optics system[5].

In general, the solution of the inverse design problems can be found by using mathematical models can control to the properties of the lens inside the scanning electron microscopy and transmission electron microscopy and determine analytically the first derivative and the second derivative for the model to design and simulate the lenses[6-8].

2. The Theoretical Treatment

Many mathematical models can represent the axial magnetic field. The axial distribution of the magnetic field for iron free magnetic lens can be represented by[9]

$$B(z)=\frac{\mu_o NI}{2lS}\left[\left(\frac{S}{2}-z\right)\ln\frac{R_2+\left(R_2^2+\left(z-\frac{S}{2}\right)^2\right)^{1/2}}{R_1+\left(R_1^2+\left(z-\frac{S}{2}\right)^2\right)^{1/2}}+\left(\frac{S}{2}+z\right)\ln\frac{R_2+\left(R_2^2+\left(z+\frac{S}{2}\right)^2\right)^{1/2}}{R_1+\left(R_1^2+\left(z-\frac{S}{2}\right)^2\right)^{1/2}}\right]\ldots(1)$$

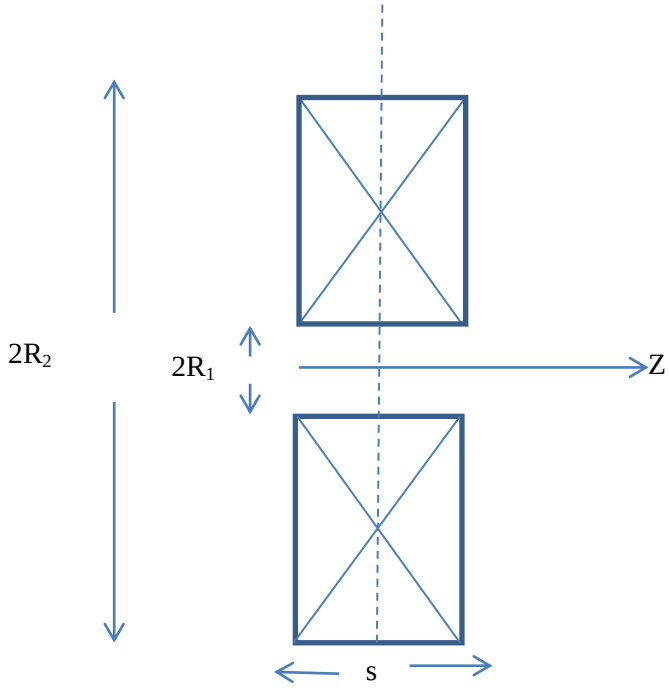
Where$\mu_o = 4\pi * 10^{-7} H/m$ and $l = R_2 - R_1$. R_2, R_1,S and z are in meters, NI in ampere turns and B(z) in teslas [9].

$\sigma A = NI$……(2)

Where σ the density of the current, A the area of the cross-section of the energizing (N the turn numbers) I the electrical current coil [9].,

$$A = \gamma(R_2 - R_1)s = \gamma ls \ldots\ldots\ldots\ldots\ldots\ldots(3)$$

Where $\gamma$the packing factor (0.9) for the copper tape winding(s is coil thickness), one can imagine the system is [9].



(iron free lens.) [9].

In the present work, the equation (1) can be modified as[modified from the researcher]:-

$$B(z)=\frac{\mu_o NI}{2lS}\left[\left(\frac{S}{2}-z\right)\ln\frac{R_2+\left(R_2^2+\left(z-\frac{S}{2}\right)^2\right)^{1/2}}{(R_1)^2+\left(R_1^2+\left(z-\frac{S}{2}\right)^2\right)^{1/2}}+\left(\frac{S}{2}+z\right)\ln\frac{R_2+\left(R_2^2+\left(z+\frac{S}{2}\right)^2\right)^{1/2}}{(R_1)^2+\left(R_1^2+\left(z-\frac{S}{2}\right)^2\right)^{1/2}}\right]..(4)$$

The inner diameter of the coil is [9]

D1=2R_1 ... ... (5)

This paper was to study the axial flux density and the paraxial ray by using the paraxial ray equation[10]:-

$$r''+\frac{\eta}{8V_r}B_Z^2(z)r=0 \text{ ... ... (6)}$$

Where r is the trajectory and V_r is the relativistically corrected accelerating voltage, η is the charge-to-mass quotient. by using the fourth order Runge-Kutta numerical method to solve differential equation (6).

The magnetic scalar potential can be calculated by using the equation[10]:-

$$B_z(z)=-\mu_o\frac{dV_z}{dz} \text{ ... . (7)}$$

Where V_z is the magnetic scalar potential, μ_o the magnetic permeability.

The inner diameter for the coil took (3, 5, 10, 15, 20) mm

Results and discussion: -

The magnetic lenses play important role in the scanning electron microscopy and transmission electron microscopy then the inverse design and the optimization draw the complete image for the lens properties which many researchers works in this line to receive for the perfect study to the samples [2, 11].

According to the equation (1), the distribution of the asymmetric magnetic field of the lens as a function of the optical axis as shown in the figure (1) with different inner radius (3,5,10,15,20), one can see the increasing the inner radius for the coil this causes decreasing the half width of the curve in addition to that the maximum value for the magnetic field distribution will be reduced as shown in the table (1)

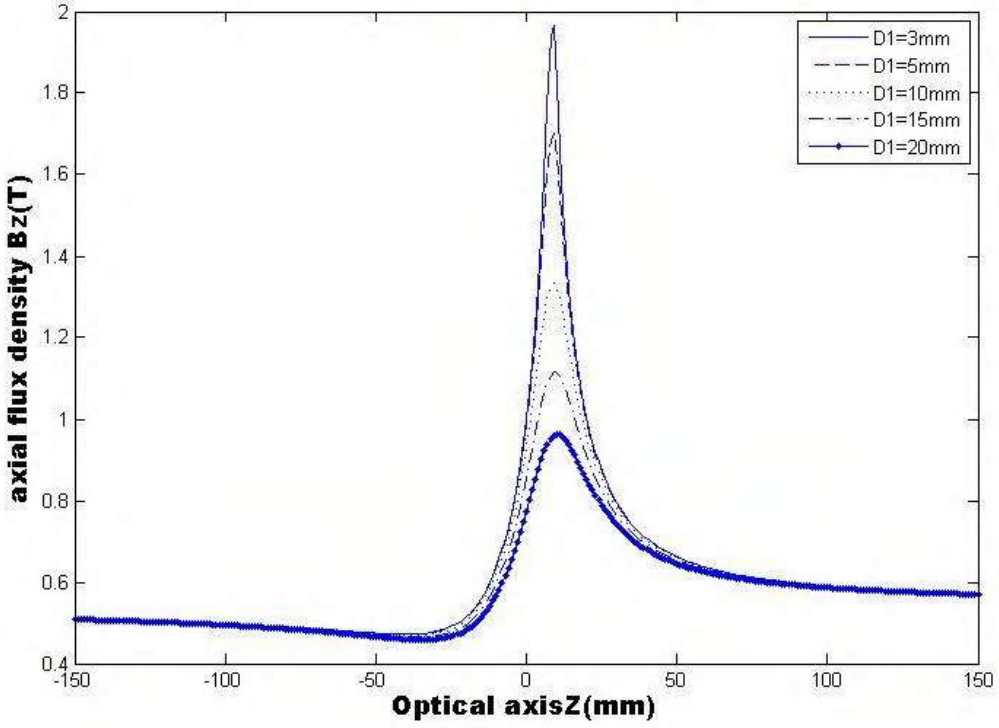


Figure 1. The axial flux density for different diameters.

Table 1. value for magnetic field distribution maximum for different value inner diameter

D1(mm)	B_{max}(T)
3	1.9658
5	1.7028
10	1.3333
15	1.1145
20	0.9617

The decreasing in the inner diameter may make the dissipation the magnetic line in the wide area in the space and this causes the weakness for the lens, this can be shown in the global papers[12, 13], which support this results. The paraxial ray under zero magnification for different inner diameters for the iron free coil can be shown in figure (2). One can show that the decreasing in the diameters causes arising the curve coming from a weakness interaction the ray with lines of the magnetic field, but in the general, the behaviour of the curve is normal focusing with the magnetic field to make the discover imagine the samples. The same speech for the figure (3) which shows the paraxial ray under infinite magnification figures (2) and (3)are deduced by using mathematical models in the magnetic field with assisted numerical determinations in the inverse design optimization with different values inner diameters[14, 15], these figures show the effects of interaction between the current and the magnetic fields which produces and the electron beam with different inner diameters. The magnetic scalar potential distributions as a function of the optical axis with variable inner diameters can be shown in the figure (4) which produced from equation (7),by this figure, one can show the decreasing the magnetic scalar potential with increasing the inner diameter this may decrease the maximum value for magnetic field distributions which effective to the magnetic scalar potential distribution because decreasing the area under the curve for the magnetic field distributions.

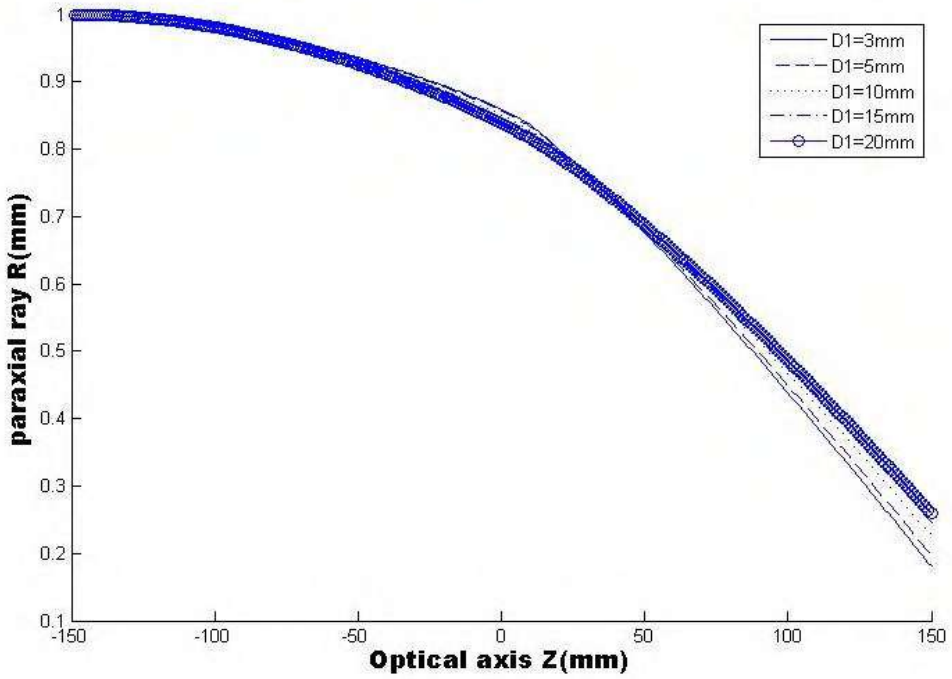

Figure 2. the paraxial ray for different inner diameters.

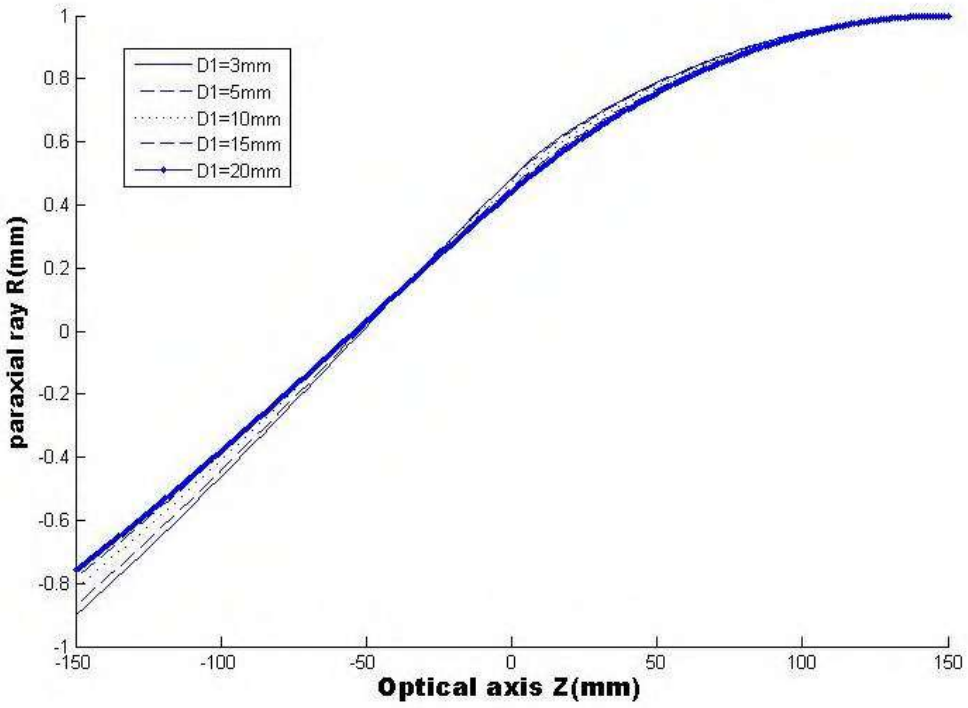

Figure 3. the paraxial ray under infinite magnification for different inner diameters.

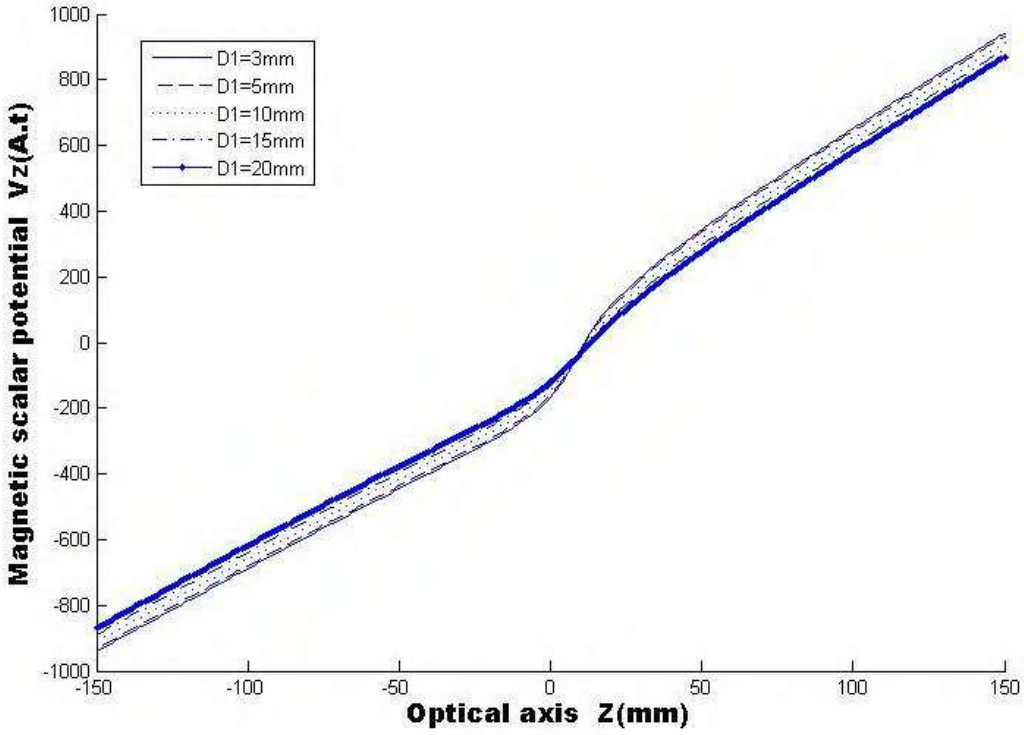

Figure 4. The magnetic scalar potential for different inner diameters.

3. Conclusion:

In this work, the effects of different inner diameter for the iron free lenses on the magnetic field distributions and the paraxial ray along the optical axis were studied. The increasing in the inner diameter causes a complication in the interaction between the electron beam and the magnetic field and makes the lens weaker. The increased diameter makes the effect and change in the magnetic scalar potential this may be due to the shape of asymmetric magnetic field distribution determined from variable inner diameter.

Abstract. This investigation presents a quantum model for electron transfer allows us to calculate the flow electronic transfer rate through metal/molecule devices. The flow electronic transfer rate at interfaces between Au metal contact with poly(9,9'-dioctylfluorene-co-bis-N,N'-(4-butylphenyl)-diphenylamine) (TFB) and solvents media with polarity is ranging from 0.315 for Diethyl ether to 0.5361 for Methanol is investigated via quantum theory of donor acceptor model. The flow rate are large with Au energy level alignment with TFB levels has been found when the potential barrier at interface is 0.066 eV with Diethyl ether solvents. Flow electronic transfer rate for Au/TFB system with methanol solvent decreased cross interface when the potential barrier is as large as 0.122 eV. This lead to produce accumulate the charges on the both side of Au and TFB when the potential at interface is large. The resulting slow transfer of electrons cross interface. Furthermore, Au metal contact on TFB molecule interface frequently with different solvents media and have large flow rate with Diethylether solvents and low flow rate with Methanol.

Keywords: Flow electronic rate, Au metal, TFB molecule.

1. Introduction

One of the important active field research in recent years is electronic transfer in different science chemistry, physical, biophysical and electronic material [1]. It has basic processes for using different materials in promises technology, such as photo catalysis, light harvesting, molecular electronics and solar cell [2]. The electronic transition field has been extended in different branch of physical, technologic material and microelectronic devices [3]. The optoelectronic and organic electronic devices have been studiedly and investigated in recent years in much more technology for applications such as Organic Light Emission Diodes (OLEDs) [4]. Electronic transfer at the levels of molecules plays an important role in different areas of physics, chemistry, biology and variety materials science [5]. After the seminal work of Marcus in 1958, the electron transfer still a more active field in different research area. The distribution of charge in condensed matter and molecules belongs to the more an important event in all photo induced processes in biology and chemical systems and

technological materials [6]. However, the levels of energy for molecules relative to levels energy for metals are the fundamental rule for electronic transfer at molecule-metal system [7]. The molecular orbital levels alignment with the Fermi energy levels of metal play an important to determine the potential barriers [8], the energy levels for Au contact with TFB are shown in Fig.1 [4,9]. In this research, the theoretical flow electronic rate at Au/TFB device are evaluated and studied via quantum theory. For the system, the transition energy, activation, barrier and flow electronic rate will be present.

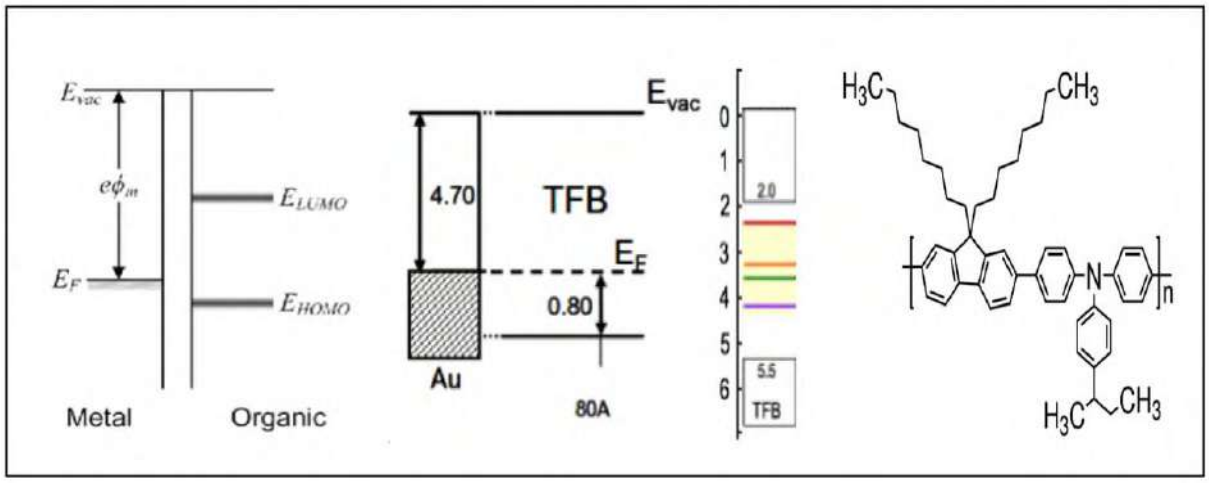

Fig.1. Illustrated of the energy levels of Au metal contact with TFB molecule [4,9].

2. Theory

The flow electronic transfer from metal to molecule cross interface is given by [10].

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\int_{-\infty}^{\infty} F(\epsilon)\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2 \delta(\epsilon_k - \epsilon)d\epsilon \quad \ldots\ldots\ldots\ldots (1)$$

Where ħ is $\frac{h}{2\pi}$, h is the Planck constant, $F(\epsilon)$ is the Fermi-Dirac occupation, $\widehat{\mathfrak{M}}_{mM}$ is coupling parameters and $\delta(\epsilon_k - \epsilon)$ is the delta Dirac function for energy at k state of metal and energy levels of molecule.

The effective density of molecule-metal states system $\rho_{ef}(\epsilon)$ is equivalent to [11].

$$\rho_{ef}(\epsilon) = \int \delta(\epsilon_k - \epsilon)dk \ldots\ldots\ldots\ldots (2)$$

The Fermi-Dirac occupation for electrons in levels state may be written as [12].

$$F(\epsilon) = (e^{\frac{\epsilon}{k_B T}} + 1)^{-1} \ldots\ldots\ldots\ldots (3)$$

Substituting the Eqs. (2) and (3) in Eq. (1) to give:

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\int_{-\infty}^{\infty}(e^{\frac{\epsilon}{k_B T}} + 1)^{-1}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2 \rho_{ef}(\epsilon)d\epsilon \quad \ldots\ldots\ldots\ldots (4)$$

We introduce the density of state for electrons $\hat{\rho}(E_i)$ in system, then Eq. (4) become.

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\int_{-\infty}^{\infty}(e^{\frac{\epsilon}{k_B T}} + 1)^{-1}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2 \hat{\rho}(E_i)\rho_{ef}(\epsilon)d\epsilon \quad \ldots\ldots\ldots\ldots (5)$$

The density of state for metal/molecule system was given:

$$\hat{\rho}(E_i) = \sqrt{\frac{1}{4\pi\Lambda_{mM}k_B T}}e^{-\frac{(\Lambda_{mM}+\Delta U^0)^2}{4\Lambda_{mM}k_B T}} \ldots\ldots\ldots\ldots (6)$$

Inserting Eq. (6) in Eq. (5) produce:

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Lambda_{mM}k_B T}}\int_{-\infty}^{\infty}(e^{\frac{\epsilon}{k_B T}} + 1)^{-1}e^{-\frac{(\Lambda_{mM}+\Delta U^0)^2}{4\Lambda_{mM}k_B T}}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2 \rho_{ef}(\epsilon)d\epsilon \ldots\ldots (7)$$

However, the electrons will be transfer above Fermi level with energy ϵ, the activation energy ΔU^0 for transfer reduced to [13].

$\Delta U^0 = \Delta\epsilon_o - \epsilon$ …… (8)

Substituting Eq.(8) in Eq.(7) reduce to.

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Lambda_{mM}\mathrm{k_B T}}}\int_{-\infty}^{\infty}(e^{\frac{\epsilon}{\mathrm{k_B T}}}+1)^{-1}e^{-\frac{(\Lambda_{mM}+\Delta\epsilon_o-\epsilon)^2}{4\Lambda_{mM}k_BT}}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2\rho_{ef}(\epsilon)d\epsilon\ldots\ldots \quad (9)$$

Furthermore, the exponent factor in the Eq. (9) simply to:

$$e^{-\frac{(\Lambda_{mM}+\Delta\epsilon_o-\epsilon)^2}{4\Lambda_{mM}k_BT}} = e^{-\frac{(\Lambda_{mM}+\Delta\epsilon_o)^2}{4\Lambda_{mM}k_BT}}\mathrm{e}^{-\frac{\epsilon(\Lambda_{mM}+\Delta\epsilon_o)}{2\Lambda_{mM}\mathrm{k_B T}}}\mathrm{e}^{-\frac{\epsilon^2}{4\Lambda_{mM}\mathrm{k_B T}}} \quad \ldots\ldots\ldots\ (10)$$

Under assume $A = \frac{(\Lambda_{mM}+\Delta\epsilon_o)}{2\Lambda_{mM}\mathrm{k_B T}}$ and $B = \frac{1}{4\Lambda_{mM}\mathrm{k_B T}}$ and inserting Eq.(10) in Eq.(9) results.

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Lambda_{mM}\mathrm{k_B T}}}e^{-\frac{(\Lambda_{mM}+\Delta\epsilon_o)^2}{4\Lambda_{mM}k_BT}}\int_{-\infty}^{\infty}(e^{\frac{\epsilon}{\mathrm{k_B T}}}+1)^{-1}\mathrm{e}^{-A\epsilon}\mathrm{e}^{-B\epsilon^2}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2\rho_{ef}(\epsilon)d\epsilon\ldots\ldots\ldots\ (11)$$

The potential barrier is given by:

$$\Delta\mathbb{V}_{ef} = \frac{(\Lambda_{mM}+\Delta\epsilon_o)^2}{4\Lambda_{mM}k_BT} = \frac{(\Lambda_{mM}+\epsilon_F-IE\,)^2}{4\Lambda_{mM}}\ldots\ldots\ldots\ldots\ (12)$$

Where ϵ_F is Fermi energy and IE is ionization energy. Furthermore, the effective density $\rho_{ef}(\epsilon)$is given by [13].

$$\rho_{ef}(\epsilon) = \rho_{\mathrm{M}}(\mathrm{E})\frac{L_M}{{d_{adm}}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}\ldots\ldots\ldots\ldots\ (13)$$

Where $\rho_{\mathrm{M}}(\mathrm{E})$ is the metal density of states, L_{ecl} is effect of coupled length and d_{adm} is atomic density metal.

Inserting Eq.(13) and Eq.(12)with Eq.(11) to obtained:

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Lambda_{mM}\mathrm{k_B T}}}e^{-\frac{(\Lambda_{mM}+\epsilon_F-IE\,)^2}{4\Lambda_{mM}}}\rho_{\mathrm{M}}(\mathrm{E})\frac{L_M}{{d_{adm}}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}\int_{-\infty}^{\infty}(e^{\frac{\epsilon}{\mathrm{k_B T}}}+$$

$$1)^{-1}\mathrm{e}^{-A\epsilon}\mathrm{e}^{-B\epsilon^2}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2 d\epsilon \quad \ldots\ldots\ldots(14)$$

Assume that

$$I = \int_{-\infty}^{\infty}(e^{\frac{\epsilon}{\mathrm{k_B T}}}+1)^{-1}\mathrm{e}^{-A\epsilon}\mathrm{e}^{-B\epsilon^2}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2 d\epsilon \quad \ldots\ldots\ldots(15)$$

Where

$$\mathrm{e}^{-A\epsilon} = 1 - A\epsilon + \frac{(A\epsilon)^2}{2!} - \frac{(A\epsilon)^3}{3!} + \frac{(A\epsilon)^4}{4!} - \frac{(A\epsilon)^5}{5!} + \cdots \quad \ldots\ldots\ldots\ldots(16)$$

And

$$\mathrm{e}^{-\mathrm{B}\epsilon^2} = 1 - \mathrm{B}\epsilon^2 + \frac{(\mathrm{B}\epsilon^2)^2}{2!} - \frac{(\mathrm{B}\epsilon^2)^3}{3!} + \frac{(\mathrm{B}\epsilon^2)^4}{4!} - \frac{(\mathrm{B}\epsilon^2)^5}{5!} + \cdots \ldots \frac{(\mathrm{B}\epsilon^2)^n}{n!} \ldots\ldots\ldots\ldots(17)$$

The solution of integrals in Eq. (15) give:

$$I = 2\mathrm{k_B T}\Gamma(1)\xi(\tfrac{1}{n}) + 2\left(\frac{A^2}{2!} - \mathrm{B}\right)\Gamma(3)(\mathrm{k_B T})^3\xi(\tfrac{1}{n^3}) + 2\left(\frac{B^2}{2!} - \frac{A^2B}{2!} + \frac{A^4}{4!}\right)\Gamma(5)(\mathrm{k_B T})^5\xi(\tfrac{1}{n^5}) +$$

$$2\left(\frac{A^2B^2}{(2!)^2} - \frac{B^3}{3!} - \frac{A^4B}{4!}\right)\Gamma(7)(\mathrm{k_B T})^7\xi(\tfrac{1}{n^5}) + 2\left(\frac{B^4}{4!} - \frac{A^2B^3}{2!3!} + \frac{A^4B^2}{2!4!}\right)\Gamma(9)(\mathrm{k_B T})^9\xi(\tfrac{1}{n^9}) + \cdots\ldots + 2\left(\frac{B^{\frac{n}{2}}}{\frac{n}{2}!} -\right.$$

$$\left.\frac{A^{\frac{n}{8}}B^{\frac{n}{2}-1}}{2!3!}\ldots + \frac{A^{\frac{n}{2}}B^{\frac{n}{4}}}{2!4!}\right)\Gamma(\mathrm{n}+1)(\mathrm{k_B T})^{\mathrm{n}+1}\xi\left(\frac{1}{n^{\mathrm{n}+1}}\right) \quad \ldots\ldots\ldots\ldots(18)$$

Inserting Eq. (18) in Eq. (14) to results

$$\mathbb{J}_{mM} = \frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Lambda_{mM}\mathrm{k_B T}}}\left|\langle\widehat{\mathfrak{M}}_{mM}\rangle\right|^2\rho_{\mathrm{M}}(\mathrm{E})\frac{L_M}{{d_{adm}}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}e^{-\frac{(\Lambda_{mM}+\epsilon_F-IE\,)^2}{4\Lambda_{mM}}}\left[2\mathrm{k_B T}\Gamma(1)\xi\left(\frac{1}{n}\right) + 2\left(\frac{A^2}{2!} -\right.\right.$$

$$\left.\mathrm{B}\right)\Gamma(3)(\mathrm{k_B T})^3\xi\left(\frac{1}{n^3}\right) + 2\left(\frac{B^2}{2!} - \frac{A^2B}{2!} + \frac{A^4}{4!}\right)\Gamma(5)(\mathrm{k_B T})^5\xi\left(\frac{1}{n^5}\right) + 2\left(\frac{A^2B^2}{(2!)^2} - \frac{B^3}{3!} -\right.$$

$$\left.\frac{A^4B}{4!}\right)\Gamma(7)(\mathrm{k_B T})^7\xi\left(\frac{1}{n^5}\right) + 2\left(\frac{B^4}{4!} - \frac{A^2B^3}{2!3!} + \frac{A^4B^2}{2!4!}\right)\Gamma(9)(\mathrm{k_B T})^9\xi\left(\frac{1}{n^9}\right) + \cdots\ldots + 2\left(\frac{B^{\frac{n}{2}}}{\frac{n}{2}!} -\right.$$

$$\left.\left.\frac{A^{\frac{n}{8}}B^{\frac{n}{2}-1}}{2!3!}\ldots + \frac{A^{\frac{n}{2}}B^{\frac{n}{4}}}{2!4!}\right)\Gamma(\mathrm{n}+1)(\mathrm{k_B T})^{\mathrm{n}+1}\xi\left(\frac{1}{n^{\mathrm{n}+1}}\right)\right] \quad \ldots\ldots\ldots\ldots(19)$$

The transition energy $\Lambda_{mM}\ eV$ for electron transfer is [14]:

$\Lambda_{mM}(eV) = \frac{e^2}{8\pi\varepsilon_o} = \left(\frac{1}{n^2} - \frac{1}{\varepsilon}\right)\left(\frac{1}{r} - \frac{1}{2R}\right)$ …… (20)

where e is electrons charge, ε_o is permittivity of vacuum, ε and n are dielectric constant and refractive index of the solvents, R is distance between the molecule and metal electrode, r is molecule radius.
the radii of material could be estimation using an expression approach [15].

$r = (\frac{3M}{4\pi ND})^{\frac{1}{3}}$ …… (21)

here M is the molecular weight, D is the mass density and N is Avogadro's number**.**

3. Results

Calculate and investigate here the flow electronic rate of metal/molecule interface and contact with each other. Use theoretical model due to quantum picture to examine the flow electronic rate of these devices, and evaluate the transition energy, driving energy and barrier for electrons. The Au/ poly(9,9'-dioctylfluorene-co-bis-N,N'-(4-butylphenyl)diphenylamine) (TFB) model is chosen to be investigated. The flow electronic transfer cross contacts that's shown in Fig.1. The transition energy can be calculated using Eq.(20) and calculated radii of metal and TFB molecule using Eq.(21) with molecule weight and mass density from Table1.Results are shown in Table 1.

Table 1. The main properties Au and TFB molecule dye [16, 17].

Properties	**Gold (Au) [16]**	**TFB [17]**
Element Formula	Au	$C_{10}H_2F_{12}$
Atomic Metal Weight (g/mol)	196.966569	350.104
Density at room temperature (g/cm3)	19.30	1.567
Crystal system	Cubic	Triclinic
Structure type	FCC	Triclinic
HOMO		5.3 eV
LUMO		2.3 eV
Fermi energy	5.53 eV	
Melting point (°C)	1064.18	
Boiling point (°C)	3825	
heat capacity (Cp) /J g^{-1} K^{-1} at 25 °C, 100 kPa	0.129	
Ionization energy		5.5 eV
Radius calculated(Å)	1.5934	4.4574

The transition energy of Au/TFB interface is strictly by dielectric constant and refractive index of solvents and radi of Au and TFB molecule, it is evaluated by Eq.(20) using characteristic of solvents from Table 2 and, R is the distance between the Au electrode and TFB molecule $R = r_{Au} + r_{TFB}$and taken the radius of Au and the TFB molecule from Table 1 and $\frac{e^2}{8\pi\varepsilon_o} = 14.4\ eV$, results are listed in Table 2.

Table 2. Calculated results of transition energy$\Lambda_{\mathrm{mM}}(\mathrm{eV})$for Au/ TFP

4. Discussion

Quantum theory model used to examine the flow electron transfer rate at Au/TFB interfaces, and evaluate the flow rate, transition energy and potential barrier at interface. The energy levels alignment of Au metal contact with TFB are showing in Figure1, i.e. the interface of Au metal energy level alignment with HOMO-LUMO energy levels for TFB molecule strictly by the Fermi energy of Au and the HOMO-LUMO energy. The positions of the energy levels of TFB molecule relative to the Fermi level of Au are shown in Figure1. The transition energy controlled electronic transfer of Au metal used contact with TFB molecule. In the majority of transition energy investigated here, the polarity estimation using the refractive index and dielectric constant in Table 3 effected forcedly on calculation the transition energy with different solvent. At the Au metal is aligned with TFB molecule, the transition energy increased with increased polarity of solvents with the fact that solvents generally form good media to level alignment with each other. Considering the fact that the transition energy are controlled to transfer of electrons from donor to acceptor we conclude that transition energy relative to the position of the energy level of highest orbitals molecule energy (HOMO), and the lowest orbitals molecule energy (LUMO)relative to Fermi energy are limited the flow electronic rate through the potential that created in interface of contact Au with TFB. The potential barrier, which simply defined as the energy difference between the ionization energy IE and Fermi level relative to transition energy. When the Fermi energy of the Au metal is relatively to ionization energy and transition energy low, making the interface potential barrier larger, it's shown that for Au/TFB with Methanol solvent has potential is equal to 0.1222 eV compare with Diethyl ether is equal to 0.0663 eV. However ,when the transition energy is large lead to potential is high, the increased transition energy making the interfacial potential barrier higher because the increased transition energy indicate the driving energy decreased because the system has more energy to reorientation energy , or small flow electronic rate .The electronic transition are most occurs when potential is low this showing for Au/TFB with Diethyl ether solvent (9.440×10^{-9} to $20.229 \times 10^{-9} \frac{\mathrm{cm}^3}{\mathrm{sec}}$) compare with less electron transfer with methanol solvent(0.842×10^{-9} *to* $1.804 \times 10^{-9} \frac{cm^3}{sec}$). The transition energy of Au metal contact on TFB molecule interfaces is energy necessarily to transfer occurs with the energy level alignments at interfaces. Different solvent media are taken to examined the transfer of electrons at Au/TFB system. While methanol solvent media shows slow flow rate, Diethyl ether and Tetrahydrofuran (THF) solvents show strong electronic transfer from Auto TFB molecule, with low potential (0.0663 eV and 0.0808 eV) and low transition energy (0.3222 eV and 0.3806eV) relatively to system with methanol has low flow electronic rate with large potential 0.1222 eV and large transition energy (0.5470 eV) for Au contact on TFB molecule.

5. Conclusion

We have determined the flow electronic transfer rate based quantum transition theory for interface of Au contact with TFB with different solvents have polarity ranging from 0.3158to 0.5361. Most importantly effects on flow electronic transfer is the transition energy, that's limited the produce electron density corresponding energies of electrons transfer. When increased the transition energy the flow rate increased electrons to transfer from donor to acceptor. In additional effect on increasing flow electronic transfer in the Au/TFB when the potential barrier is small (0.066 eV). The flow rate of electronic transfer decrease with increasing the potential energy and decreased the electronic rate when increased the potential energy at interface. The Diethyl ether is topic media with Au contact with TFB molecule found to yielding large flow electronic rate and low potential barrier than the bottom Methanol solvent founded to yielding small flow electronic rate and high potential barrier at interface.

Abstract. In this study, 88 healthy adults in Al-Najaf governorate of Iraq have been divided into three groups according to the type of exposure to radiation including environmentally uranium exposures n=29 (G_1), occupationally exposures n=27 (G_2), and non-uranium exposures n=32 (G_3). All groups were subjected for estimation of uranium concentration in urine samples using CR-39 SSNTD method beside measurement of urine concentrations of 8-OHdG compound as a biomarker for oxidative DNA damage using Elisa technique. Reactive oxygen species produced under the effect of many causes including ionizing radiation exposure, ($OH^{\cdot}$)free radical induced the formation of 8-OHdG compound from cellular and mitochondrial DNA through attack of C-8 in purine ring of guanine base. The results showed that mean values of uranium concentration were (1.836±0.426 µg/L), (2.02±0.404 µg/L) and (1.755± 0.437 µg/L) for group1, group2 and group3, respectively. While mean values for 8-OHdG were (49.810±15.484 ng/ml), (47.717±14.232ng/ml) and (46.769±14.249ng/ml) for the three groups, respectively. No significant statistical differences were recorded between all data obtained. These results suggested the presence of uranium pollution in all groups including the non-exposed group as compared with reference value of (WHO, 2004). Results also demonstrate the presence of DNA oxidative damage in all groups according to concentration levels of 8-OHdG in urine samples. Therefore, the uranium pollution in urine samples of the examined groups indicate the presence of chronic low dose radiation source in Najaf governorate, which might be the cause of DNA damage as reflected by the urinary levels of 8-OHdG compound.

Keywords: uranium concentration, 8-OHdG concentration and urine sample.

1. Introduction

Environmental pollution with many chemical and physical factors can be hazardous to people health. Humans are constantly exposed to many agents derived from exogenous sources such as food, tobacco smoke, air pollution or ionizing radiation [1]. Ionizing radiation is a high energy radiation that produces ionization or electrical charges as it passes through medium or matter [2]. There are three types of atomic radiation of concern to human health namely, α, β and γ. Sources of radiation may be natural (80%) or human made (20%) [3,4]. The most dangerous human made source of ionizing

radiation is the misuse of forbidden weapons as what happened in Gulf war I and II in Iraq (1990-2003) Which caused depleted uranium pollution in limited areas of Iraq [5].

Exposure of healthy humans to Reactive Oxygen Species (ROS) agents can induce as a situation called oxidative stress [6]. This is characterized as a situation in which the antioxidant protection capacity is overwhelmed by an increase in the generation level of ROS resulting in oxidative damage to cellular macromolecules such as lipids, DNA and proteins [7]. Balance is preserved between endogenous oxidants and various enzymatic and non-enzymatic antioxidants under normal conditions and in all aerobic species [8]. The most important free radical causing damage to basic macromolecules is the hydroxyl radical ($OH^{\cdot}$) which attack nuclear DNA and mitochondrial DNA causing addition of ($OH^{\cdot}$) to c-8 of purine ring in guanine base and produce c-8-OH radical which lead to formation of 8-hydroxy-2-deoxyguanosine (8-OHdG) [9].

This compound is then used as biomarker to examine the oxidative DNA damage, its discovery reported for first time by Kasai and Nishimura in1984 [10]. ROS correspond to super oxide anion ($O_2^{\cdot -}$), singlet oxygen ($O_2^{\cdot}$),hydroxyl radical ($OH^{\cdot}$), hydrogen peroxide (H_2O_2), and nitric oxide (NO) are crucial for many physiological processes and usually exist in cell in a balance with biochemical antioxidant like enzymes including catalase, glutathione peroxidase, superoxide dismutase and low molecular weight antioxidants such as (β-caroten and tocopherol) [7]. It is suspected that oxidative stress leads to the onset and progression of many diseases and the natural aging process [11]. ROS are highly reactive and have an extremely short half-life, so their direct determination is normally impractical [12].

Measuring oxidative modified cellular constituent biomarkers like DNA in biological samples offers a promising public health strategy in the field of public health [13]. In pathological conditions such as carcinogenesis, coronary heart disease and diabetes, measurements of urinary 8-hydroxy-2-deoxyguanosine (8-OHdG) have been extensively studied [14,15]. In recent years, (8-OHdG) has been commonly used not only as a biomarker for endogenous DNA damage assessment but also as a risk factor for many diseases including cancer [16]. Also (8-OHdG) has been used to estimate DNA damage after exposure to agents causing cancer such as:(tobacco smoke, asbestos fiber, heavy metals, and polycyclic aromatic hydrocarbons) [17]. Ionizing radiation (IR) has been reported as one cause of oxidative stress and DNA damage [1, 18, 19].

In Al-Najaf governorate of Iraq, there are some uranium concentrations either naturally (Al heera uranium mine) or human made pollution, while other regions in the governorate are supposed to be not polluted. The present study aims to evaluate uranium pollution in urine samples of uranium-exposed and non-exposed samples. Moreover, estimation the urine concentration of (8-OHdG) compound as a biomarker for DNA oxidative damage and its health consequences.

2. Materials and method

2.1. Collection and Preparation of the Samples

2.1.1. Groups of study

To measure the uranium concentrations, 88 urine samples were collected from three different groups of adults in Al-Najaf governorate as described below.

1. Group one (G1): Included 29 healthy people living in expected polluted areas such as the village of Al-Zajri near the uranium mine in Al-Heerradistrict in Al-Manathera, the village of Al-Aama in Al-Abbasiyeh district in Al-Kufa, as well as Al-Ansar neighborhood.
2. Group two (G2): Included 27 healthy people exposed to uranium radiation by virtue of their work, from Al-Sadr Medical City employees, Al-Hakim General Hospital, Consultative Clinic for Chest and Respiratory Diseases, Middle Euphrates Cancer Center.
3. Group three (G3): Included 32 healthy people living in unpolluted areas, from some sporadic areas of the governorate.

2.1.2. Sample Collection

The sample was taken from the adult person containing urine cups (60 ml); and immediately acidified by adding 1 ml of concentrated HCl for each sample to prevent urine sample polymerization, then placed in a cooling box until the bio-laboratory was reached.

Each urine sample divided by two parts in test tubes: first for uranium concentration estimation by SSNTD technique using CR-39 detector, second for 8-OHdG concentration measurement in urine samples by ELISA technique.

2.2. Measurement of Uranium Concentration

A CR-39 detector was made by Pershore Moulding LTD Company UK, with a thickness of 500μm, was put in the first part from urine samples for measuring the Uranium concentrations, for 90 day. Each detector was cut into 1×1 cm^2 an area; the tubes are stored at -80˚C in the deep freezer. At the end of this period, the exposed detectors were etched using sodium hydroxide (NaOH) solution at a temperature of 70º C for 5 hrs. The normality of solution was set at 6.25 in the water bath. These etched detectors were then washed using distilled water. The track density of each CR-39 detector (track/cm^2) was calculated using an optical microscope (NOVEL, China) with a magnification power of 10×40. The reading of each detector was corrected for the background radiation. The tracks density of uranium from stander solution calculated according to the following relation [20].

$(\rho) = N / (A \times t)$ …….(1)

Where ρ = Track density (no. /cm^2.h), N = Average number of tracks, A = Area of field view (cm^2), t = Time of exposure (h).

To calculate the Uc in the serum sample one could use the following fitting equation [21]:

$Uc=(\rho +12.5) / 18.6$ ……. (2)

2.3. Measurement of 8-Hydroxy-2'-Deoxyguanosine (8-OHdG)

The competitive inhibition enzyme immunoassay technique is employed in this assay. The 8-OHdG-specific antibodies were pre-coated onto a micro plate. Standards and samples were pipetted into the wells with 8-OHdG conjugated with Horseradish peroxidase (HRP). Between 8-OHdG (standards or samples) and HRP conjugated 8-OHdG with the pre-coated 8-OHdG specific antibody, a competitive inhibition reaction was launched. The further 8-OHdG in the samples, the less HRP-conjugated 8-OHdG is bound by the antibodies. A substrate solution was applied to the wells after being washed to eliminate any unbound reagent, and color was produced in comparison to the amount of 8-OHdG in the sample. The production of color was halted and the color intensity was assessed. In urine samples, the 8-OHdG content is determined by comparison with a predetermined normal 8-OHdG curve.

3. Results and Discussion

3.1. Uranium concentration in examined groups

Results of present study are reported in table (1) which shows the mean values of uranium concentrations in urine samples of uranium healthy exposures by environmental contamination (G_1),uranium healthy exposures by virtue of their occupations (G_2), and non-uranium exposures healthy people (G3) in Al-Najaf governorate were (1.836±0.426) μg/L, (2.020±0.404)μg/L and (1.755±0.487) μg/L respectively, other local studies reported uranium concentration in urine samples of healthy control in Baghdad city (0.464-6.212) μg/L [22], (3.212±0.593) μg/L [23], (1.361) μg/L for male, (0.9533) μg/L for females, (3.196) μg/L, for radiation field workers [24].

The standard value of uranium concentration in urine will be 0.3 μg/L after 30 years of continuous exposure to 15 μg/L uranium concentrations in drinking water [25]. According to standard value, the results of present study suggested the presence of uranium pollution in all of the studied groups including healthy group of non-polluted areas of Al-Najaf governorate (G_3).

Uranium concentration in all urine samples may reflect the presence of general environmental pollution with ionizing radiation in Najaf governorate. In Iraq, the levels of depleted uranium raised

after misuse of weapons forbidden in Gulf war I and II causing environmental pollution with uranium in limited areas, but no procedures had ever been taken to isolate these contaminated areas all over Iraq to stop and avoid the spreading of this radioactive contamination and its dangerous consequences [26, 27]. The average annual intake of uranium by adults has been estimated to be 460 μg from ingestion and inhalation [28]. Most of α-emitting materials leave the body through feces, small portion of urine will get into blood and the body can get rid of within few days, and the rest can stay in bones, kidney, liver pancreas, spleen, and central nervous system.

If we breathe the dust of α-emitting material, some of it is exhaled and some stay in our lung [29, 30]. The results of present study showed that mean value of uranium concentration in urine of G_2 is higher than that of G_1 and G_3, this might be obtained because this group (G_2) exposed to both environmental and artificial ionizing radiation sources. The natural environmental radiation is inevitable. It has been recorded that the annual effective dose produced by artificial sources likes X-Ray machines and other diagnostic systems is nearly equal to the total radiation dose obtained from natural dose [31].

In their effects on matter, natural and artificial radiation sources are identical. The U.S. Nuclear Regulatory Commission (NRC) mandates that its licensees restrict human radiation exposure to 1 mSv per year for individual members of the public and limit occupational radiation exposure to 50 mSv per year for adults employed with hazardous materials above the background level of radiation exposure.

3.2. Concentration of 8-OHdG as biomarker for DNA damage

Table (2) demonstrates the concentrations mean values of 8-OHdG compound as a biomarker for DNA damage in urine sample were (49.810±15.842 ng/ml), (47.717±14.232 ng/ml), (46.769±14.249ng/ml) in G_1, G_2 and G_3 respectively. A local study reported 8-OHdG concentration in urine samples of healthy people in Baghdad city as (283.96±43.14 ng/ml) [32]. Comparing the results of the present study with the results of non-local same studies on healthy people it was clear that the concentration of 8-OHdG in Iraqi people in much higher than that of other populations where it was (9.08 ng/dl) in Makkah [33], (1.32±0.20 ng/ml) in Turkey [34], (1.53 ng/ml) in Portland [35], (12.29±5.72 ng/ml) in China [36], (8.43 ng/mg creatin) in Japan [7], (15.2±5.71 ng/mg creatin) in Japan [6]. Studies on healthy people recorded that urinary 8-OHdG is associated with arteriosclerosis related factors [7]. Diet also related to urinary 8-OHdG. For fruit intake a significant correlation for an observed decrease in DNA damage level with increasing fruit intake for females [1].

The increased level of 8-OHdG concentration in urine samples of all study groups suggest DNA damage because of oxidative stress. Also, all urine samples were uranium polluted according to mean values estimations of uranium concentrations. Ionizing radiation is one cause of oxidative stress and can damage any part of cell and interfere with many cellular processes and DNA is the most critical biological target. There is no safe level for radiation exposure; any level could be harmful [37]. Ionizing radiation as a toxicant and carcinogen can produce ROS and cause severe oxidative damage such as single and double strand break, oxidized base and DNA protein cross link.

If these damages are not repair correctly, they may lead to gene mutation and cancer [34], oxidative damage of DNA by reactive oxygen and nitrogen species leads to production of 8-hydroxy-2-deoxyguanosine (8-OHdG) which is a specific biomarker for oxidative stress [38]. Normal value of 8-OHdG found to be significantly different in terms of age, gender, smoking and alcohol consumption but not different in term of body mass [7]. In recent years, 8-OHdG compound has been commonly used not only as a biomarker for endogenous DNA damage assessment but also as a risk factor for many diseases, including lung cancer, in many studies [12], ovarian cancer [39] and breast cancer [33]. Measuring oxidative modified cellular constituent biomarkers, including 8-OHdG for DNA damage in biological samples, is a promising strategy in the field of public health. It has been discussed before that a promising future is to incorporate knowledge from genome programs to broaden the scientific frontiers on etiology health risk prediction and prevention of environmental disease risk by developing a reliable biomarker database [40]. ROS produced under the effect of ionizing radiation induce the formation of 8-OHdG compound from cellular and mitochondrial DNA, hydroxyl radical ($OH^{\cdot}$) plays important role in producing 8-OHdG. The 8-OHdG estimated in urine

and blood cells as a biomarker for oxidative DNA damage [16]. The results of G_2 showed high level concentration of 8-OHdG and the highest level of uranium concentration in urine samples. It has been reported that occupational exposure to low dose radiation is prevalent with wide-spread applications of ionizing radiation in several industries. While the International Radiological Safety Commission recommends an effective dose limit of 20 mSv for an average of 5 years and the effective dose should not be greater than 50 mSv in any single year [31].

4. Conclusions

The percent study demonstrates that the uranium pollution is presence in urine samples of all the examined groups reflecting the presence of chronic low dose radiation source in Al-Najaf governorate. Moreover, uranium pollution contributes to DNA damaging in all of the scanned groups. The oxidative damage of the DNA means higher probability of many diseases mainly cancer, a point which needs more investigations.

University of Baghdad, College of Science for Women, Department of Physics, Iraq.

E-Mail: sumaha_phys@csw.uobaghdad.edu.iq

Abstract. Preparation of an environmentally friendly organic green dye, an alternative to the harmful industrial chemical green dye which is used to optical and industrial applications. The dye is extracted from spinach plant by solvent extraction process. The optical and morphological characterizations of green spinach dye are measurements, the absorbance spectrum of green spinach accord in visible region and the dye have two peaks at wavelengths (λ_1=440 nm, λ_2=685 nm) where the band gap energy is E_g=2.81 eV at λ_1 and the refractive index of spinach dye (n=1.36682). The fluorescence spectrum show the maximum absorption wavelength λ_1, λ_2 shifted towers red region about $\Delta\lambda_1$=90 nm and $\Delta\lambda_2$=195 nm respectively, and that accentuated the absorption region are extend to the dye. Also, the average particles size of spinach measured by Atomic Force Microscopy (AFM)=59.587 nm. These characterizations obtained the green dye can used in optical and industrial applications and made it a safer alternative for the toxic chemical green dye and thus protecting the environment by replacing polluting industrial chemical and their consequences.

Keywords: Extracted Spinach Dye, Optical Properties of Spinach Dye, and Spinach plant.

1. Introduction

Given the modern orientation to renewable energies using environmentally friendly natural dyes instead of chemical dyes harmful to environmental. The natural green spinach dye has been extracted and its characteristics studied to determine the extent of its use in various optical, industrial and scientific applications. Spinach is a plant belongs to chenopodiaceous family [1]. It is cultivated throughout the word as cool season annual, green leafy vegetables with significant nutritional and beneficial properties [2]. Spinach featuring in low calories is considered as a good source of minerals like iron and calcium and multivitamins [3]. It is also native to central and south western Asia. This green dye can be used in different application like; optical application [4], chlorophyll laser [5], chlorophyll dye is suitable to replace harmful tracer dyes for laser [6], possibility to replacement of green chemical dyes that are used in industry by organic dyes [7], dye sensitized solar cell (DSSCs) [8] and other applications.

In this work, green spinach dye was extracted and preparation by used ethanol, to illustrated the spinach characteristics and how much ability of use in optical and industrial applications.

2. Materials and methods

2.1. Materials

Materials used are fresh green spinach plant, ethanol and deionized water.

2.2. Preparation the organic green spinach dye

Use the solvent extraction process to extraction the spinach dye by cleaned the spinach leaf in deionized water, dried, 200g of spinach squeezer using blander, then filtering as shown in Figure 1. Added 20 ml of ethanol and placed into stirrer for 2h.

Figure 1. Shows spinach leaf, spinach squeezer using blander and filtering the dye extractor respectively**.**

2.3. Characterization and measurements

The absorbance (A) spectrum of the dye accomplished using UV-Vis shimadzu spectrometer in the wavelength of (190-1100)(nm), is use to measure the absorption rate in visible area. The optical band gap (E_g) calculated by using formula in (1)[9]:-

$$E=h\upsilon=hc/\lambda \quad (1)$$

Where E is the stands for photon energy, h is blank's constant (6.626×10^{-34} j.s), υ is the frequency, c is the speed of light (3×10^{8} m/s) and λ is the wavelength.

Measured the absorption coefficient (α) to determine the light transmittance in material, if α is spadesful, its meaning the transmittance light in material is attenuation and if α is small amount the material is transparent to ray passing through it. The α calculated from absorption A and thickness d of cavity of dye solution (=1 cm) using formula (2)[10]:-

$$\propto = \frac{(2.303)A}{d} \quad (2)$$

The extinction coefficient K_0 used in spectroscopy to measure the concentration of a chemical in solution and calculated by using formula in (3) [10]:

$$K_0 = \frac{\propto \lambda}{4\pi} \quad (3)$$

The refraction index n of the spinach dye was measure by Refractometer-AR4 device from Germany. The fluorescence of spinach dye measured on the fluorescence spectrophotometer Agilent on wavelength of 200-900 nm. To determination probable chromophore groups in a given natural dye infrared (IR) spectra were recorded with Fourier transform spectroscopy FTIR spectrometer from SIDCO (FTIR-600).

The surface roughness of the spinach dye was measured by atomic force microscopy (AFM), made by (DME) model (DS95), scan range 50-200 μm and sample size up to 150 mm.

3. Results and discussion

Multiple measurements of the dye conducted to find out the properties and the characteristics of the dye. The optical characterizations, absorbance, band gap energy, absorption coefficient, extinction coefficient, refractive index, fluorescence and transmittance of spinach dye obtained by (AFM). The observed results are summarized in the following subsections.

3.1. Absorption of spinach dye

Figure 2 refers to the UV-Vis absorbance spectrum of spinach extracted with ethanol spectrum of spinach extracted with ethanol in the visible light spectrum. The dye have two peaks (λ_1=440 nm, λ_2=685 nm) in cyclohexane indicated the existence of either anthocyanin, chlorophyll, carotene or mixture of them which have absorption peak at wavelength 420 nm and 665 nm [11].

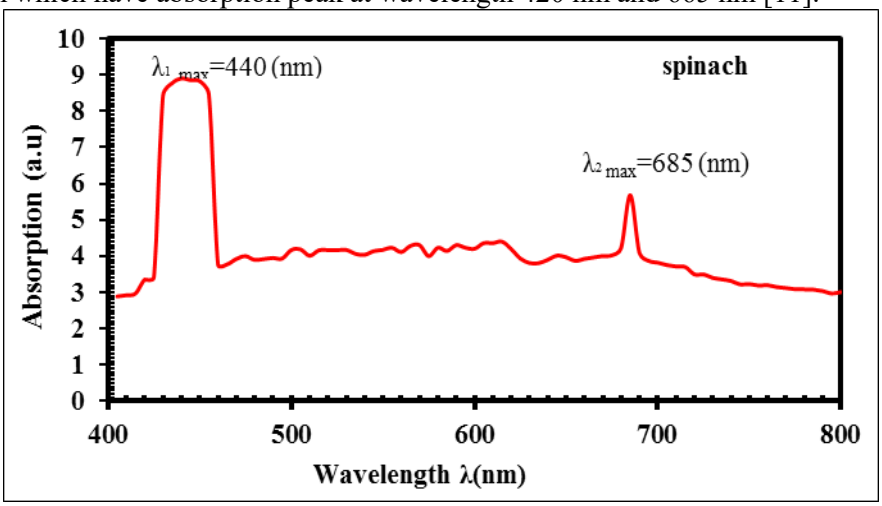

Figure 2. The absorption spectra of spinach extracted with ethanol have two peaks (λ_1=440 nm, λ_2=685 nm).

Spinach is fertile in chlorophyll due to all green plants consisted of chlorophyll, which qualified for photosynthesis operation having glucose from simple organic molecules (carbon dioxide and water) under the action of visible radiation [12]. The band gap energy of spinach dye is (E_g=2.81 eV at maximum wavelength λ_{max}=440 nm) was calculated by formula 1. Figure 3 refer to absorption coefficient α which is a function of wavelength and depends on absorbance and thickness of the film according to the formula 2.

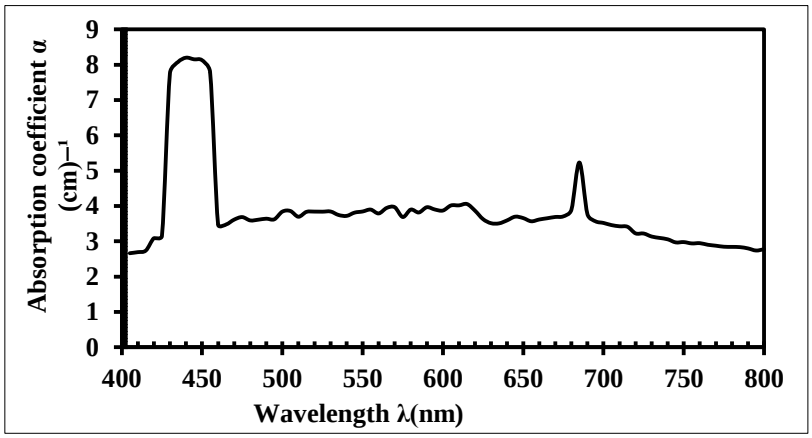

Figure 3. Absorption coefficient (α) of spinach dye.

Figure 4 represent to extinction coefficient of spinach dye which increases by increasing the absorption coefficient and wavelength calculated by formula 3.

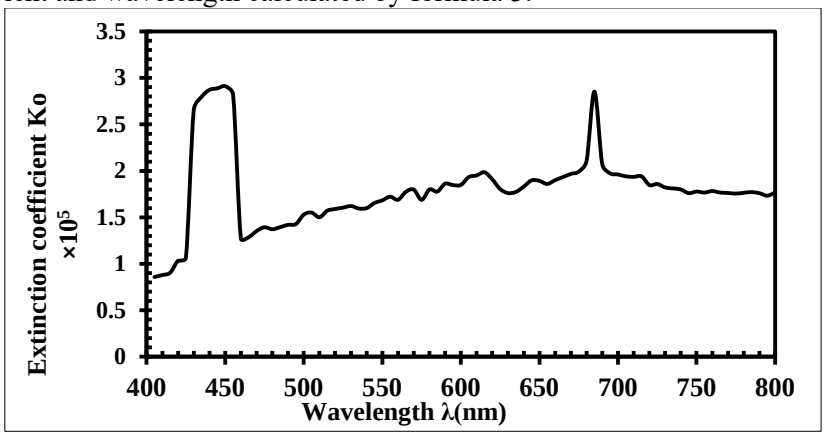

Figure 4. Extinction coefficient of spinach dye.

3.2. Refractive index of spinach dye.

The refractive index n of spinach dye (n=1.36682) is measured by Refractometer device in liquid phase.

3.3. Fluorescence of spinach dye.

Figure 5 demonstrated fluorescent spectrum, after excitation with two peaks in wavelengths (440, 685) (nm) as functions of emitted radiations wavelengths at (λ_{f1}=530 , λ_{f2}=880)(nm). Fluorescents maxima with respect to absorptions maxima shifted as ($\Delta\lambda_1=\lambda_{f1}-\lambda_{1max}$ =90 nm) with applicate the same equation to the second peak at ($\Delta\lambda_2=\lambda_{f2}-\lambda_{2max}$ =195 nm), the fluorescence spectra shifted towards red region and thus agreement with searcher [13].

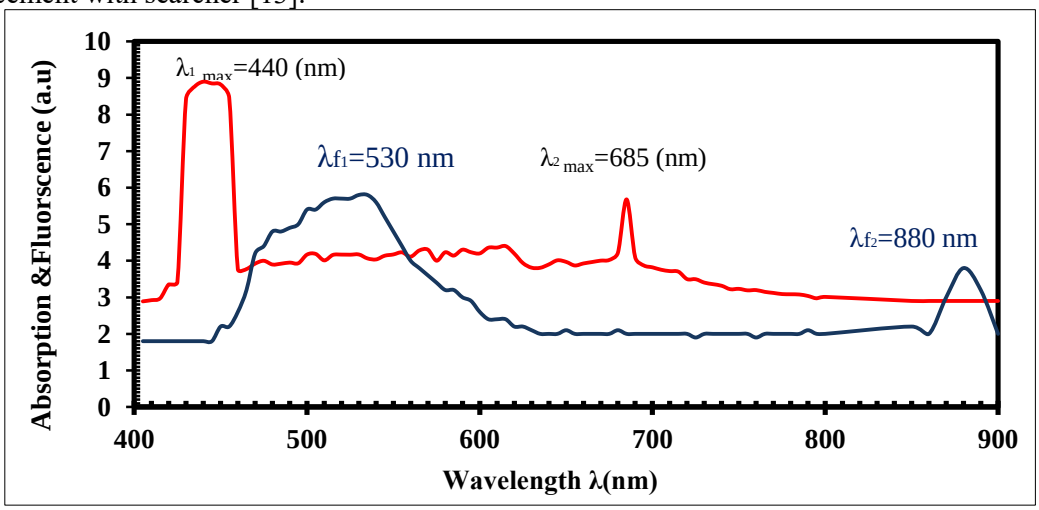

Figure 5. Fluorescent spectrum of spinach dye and the maxima shifts ($\Delta\lambda_1$=90 nm and ($\Delta\lambda_2$=195 nm), the fluorescence spectra shifted towards red region.

3.4. Infrared-IR spectroscopy of spinach dye.

The FTER spectra of spinach as shown in Figure 6. In IR spectrum, the absorption band of iron sulphides is not clear at lower wavenumber. While, the presence of sulfate is indicated by the appearance of asymmetric stretching of carboxylate C=O_2 and a band at 1056 cm^{-1}.Whereas, the existence of a band at 2356 cm^{-1} is attributed to the presence of ferredoxin (Fe-S). In addition, (-OH) vibration cause the occurring of a band at 3431 cm^{-1}, while the band occurring around 2923 cm^{-1} attributed to the stretching mode of (C-H) in the spinach.

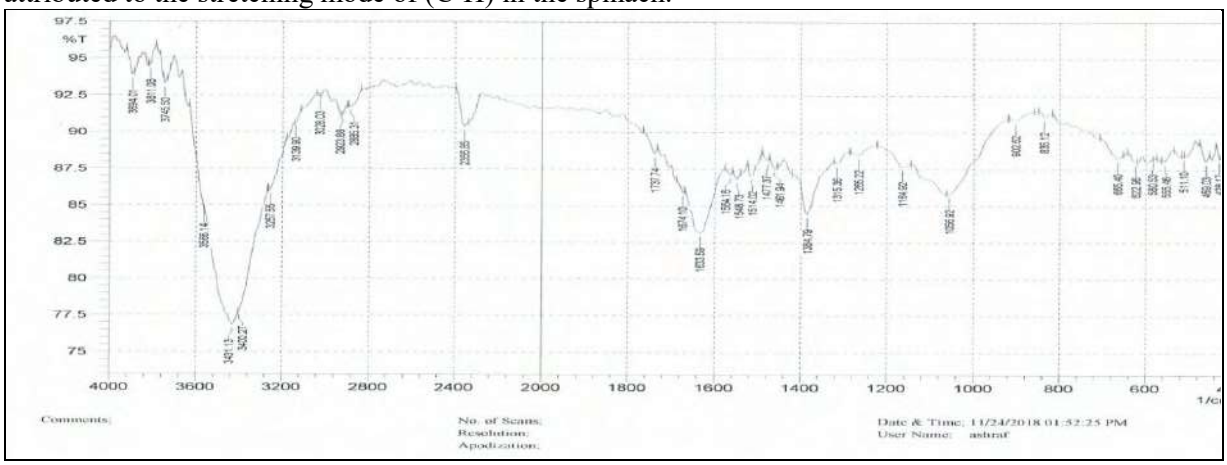

Figure 6. FTER spectra of spinach dye.

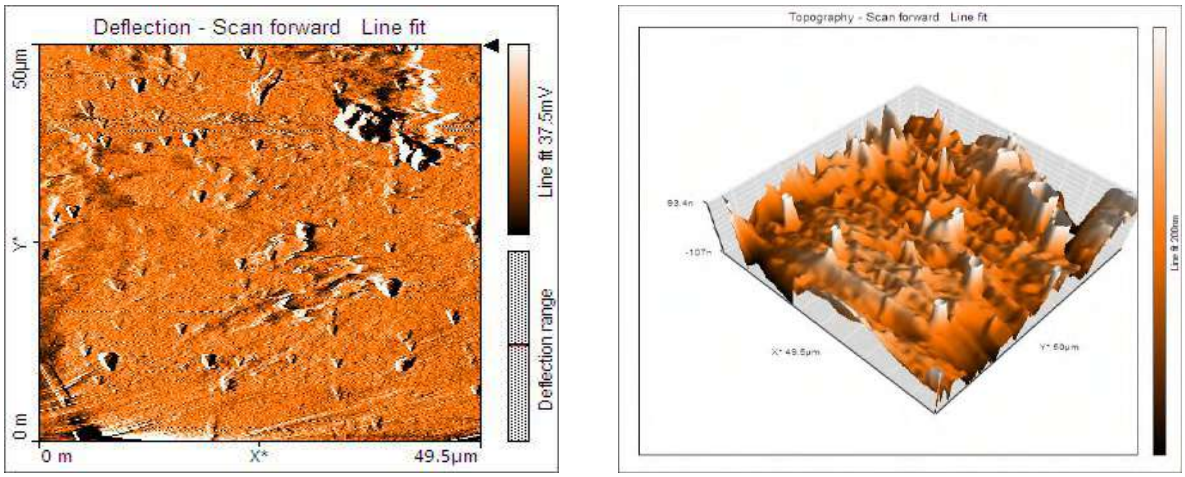
*3.5. Atomic force microscopy (AFM) of spinach d**Error! Reference source not found.**ye.*

The AFM analysis the surface morphology and roughness of spinach dye. The roughness average 31.152 nm, and the average particle size 59.587 nm, determine using 2D, 3D images as shown in Figure 7. These results agreed with searcher [15].



a) 2D **b) 3D**

Figure 7. AFM image of spinach dye in (a) 2D image, (b) 3D image.

4. Conclusion

Synthesis an organic green dye extracted from spinach plant used as alternative to green chemical dyes which are toxic and harmful to environment. The spinach dye have two peaks in visible region at wavelength λ_1=440 nm, λ_2=685 nm and the fluorescence shifted $\Delta\lambda_1$=90 nm and $\Delta\lambda_2$=195 nm respectively, these shifts contributed to extend the absorption spectrum to the dye, also found the band gap energy E_g=2.81 eV at λ_1, the refractive index of spinach dye n=1.36682 and the average particle size 59.587 nm. These characterizations elucidate the green spinach dye can used in optical and industrial applications because it was friendly to environment, safe and have multiple uses. Spinach dye is a good alternative to green chemical dyes. In the future, is possible to extracted natural dyes from origin with different colors to be used in optical and industrial applications instead of harmful chemical dyes.

Abstract. In this study, density function theory was used to evaluate geometrical and electronic properties for pure and doped system as well as adsorption energy. Pure graphene nano-ribbon appeared in plane surface during adsorption energy to have low sensitivity to methane gas. Its energy gap changed only in distance 1A because of the chemical adsorption. Doping mechanism enhanced the proprieties of graphene nano-ribbon. In geometrical structure, copper (Cu) atom stretching the nano system and it is a sign of modification. Additionally, energy gap was decreasing by doped in transition metal atom and become opening. Adsorption energy of doped system was higher than pure nano-ribbon. It was noticed that the doped transition metal enhanced the sensitivity of the system 6 times greater than pure graphene nano-ribbon. Doping graphene nano-ribbon by copper atom revealed to be a key to design chemical and physical gas sensor for methane gas.

1. Introduction

Graphene as a two-dimensional connected carbon sheet is an excellent material that has exceptional properties such as superior surface to volume fraction, little electrical noise and outstanding transport properties[1]. Graphene has more superior efficiency in addition to its unique two-dimensional structure and has unique chemical properties such as outstanding electrical, optical and mechanical properties. Due to its excellent properties, graphene has been commonly used in a number of ways, such as energy generation, spintronics and field effects transistor (FET)[2]. Graphene has also been proven to have possible uses in detection molecules, both experimental and theoretical methods. Graphene could be employed as a novel material for adsorption and desorption due to its low dimensions and wide surface area process [3]. Graphene is a zero band gap semiconductor with its valence and conduction bands touching in corner of the Brillion zone in called Dirac points [4]. However many theoretical and experimental studies showed that graphene has weak physical adsorption of most gas molecule[5]. Therefore, researchers utilized many mechanisms such as defect vacancy and doped graphene by metal atom[6]. Graphene doped by metal atom led to significant structural and electronic properties, also electrical conductivity and chemical reactivity during adsorption process to detection small gas

molecule[7]. It is noteworthy that doped graphene by metallic atom creates modifications process without damaged one atom thick of it[8]. Many studies showed that the introduction of defect or doped metallic atom in graphene will modify the charge transfer strength between it and gas molecule adsorbed, also enhance sensitivity and selectivity of gas-based sensor[9]. Gas sensing was important environmental issue for hazard toxic gases molecule. Thus, this study is mainly focused on used different nano-system for detaction methane gas.

2. Theoretical background

In order to investigate the electron systems' electronic structure, density functional theory (DFT) is employed for this purpose which is widely used quantum mechanical method in physics and chemistry. DFT usually applied to evaluate the ground-state properties of metals semiconductors as well as insulators. Furthermore, DFT is a useful method in physics and chemistry computational [10]. Historically, in 1927, the starting point for the theory of density was the Thomas-Fermi model. They defined the energy of an atom by representing its kinetic energy as a function of electron density, combining this with the classic expressions for interactions among nuclear-electron and electron-electron, which can also be defined in terms of electron density [11, 12]. The DFT focuses on the much simpler electron density $\rho(r)$.DFT's central concepts are dependent on ground state energy. Others ground state electronic properties are determined uniquely by the density of the electrons [13, 14]. However, the exact ground conditions of the system correlates to the electronic density for minimal total energy.

3. Materials and Research Aim

(GNR), (Cu-GNR) and CH_4. DFT method was used to computed structural, electronic and adsorption energy for pure and doped graphene by Cu atom. The aim of present study is design sensor for toxic gas. The equations below were used in the study.

Adsorption energy = $(E_{gas}+E_{ribbon})-E_{(gas+ribbon)}$[15] (1)

Where E_{gas} total energy for adsorption gas, E_{ribbon} is total energy for nano-system and $E_{(gas+ribbon)}$ is total energy for adsorption system.

Energy gap=$E_{LUMO}-E_{HOMO}$ [16] (2)

4. Result and discussion

4.1. Geometrical proprieties

Geometrical characteristics summarized on bond length and angle between atoms computed for graphene nano-ribbon when toxic gas molecule absence. Fig. 1 lists the geometry structure for pure graphene nano-ribbon. Bond lengths for C-C, C=C, C=C (aromatic) and C-H are (1.4555), (1.3661), (1.4305) and (1.0859), respectively [15]. Angles between atoms listed for (C--C--C) and (C=C-H) are 120.232 and 119.922 degree, respectively[15]. For doped nano-ribbon, Fig. 2 illustrated a geometrical structure for G-Cu nano-ribbon. Bond length between carbon-carbon for all type's agreement with previous study [16]. The bond length between Cu-C are varies between 1.8427-1.8672 Å. Computed bond length for metal-carbon was agreement with study [16]. The angle between carbons atoms are agreement with past section also. Bond angel between Cu atom and three neighbor atoms are 85.3641-103.7705 degree. Bond angle for system under study agreement with [17]. Also that clear copper atoms stretching structure of graphene nano-ribbon because the radius of it greater than carbon radius [18].

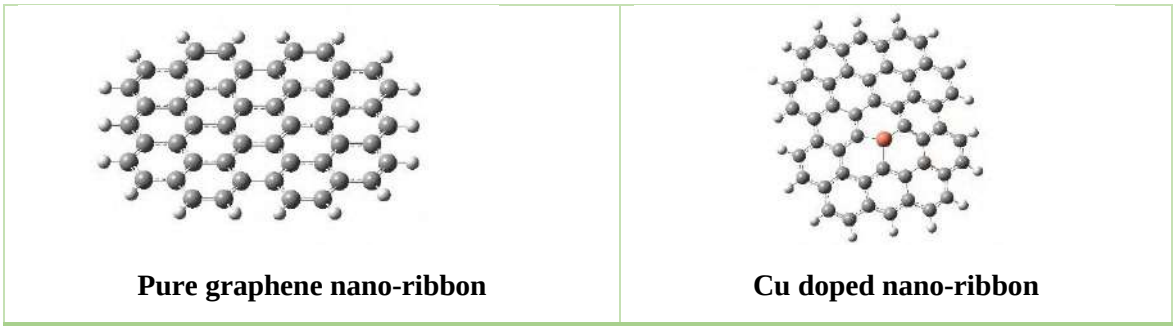

Fig.1. Geometrical structural for pure and doped nano-ribbon.

4.2. Adsorption energy

In this section, study adsorption energy for pure graphene nano-ribbon compared with doped system. For pure system CH_4 gas molecule reaction with graphene is low activity. The absolute energy value increasing from zero to 2 eV at distance 4-1.5 Å all these distances refer to physical adsorption. Chemical adsorption appears only when bonds formed between H related to gas with C of graphene nano-ribbon. For doped system CH_4 has adsorption energy greater than pure nano-ribbon, modification of interaction process was clear. In addition, findings indicated that G-Cu system sensing CH_4 gas for all distance. Finally, results indicated that G-Cu system has high sensitivity for $CH_{4(doped)} > CH_{4(pure)}$. Table 1 listed the values of adsorption energy and Figure 2 showed the curves of adsorption energy measured in eV unit.

Table 1. Values of adsorption energy for system under study measured in eV unit

D (A)	Pure nano-ribbon	Doped nano-ribbon
1	-7.3088	-45.2869
1.5	-2.1496	-6.6194

3	-0.01360	-0.4187
3.5	0.001532	-0.4676
4	0.002721	-0.4974

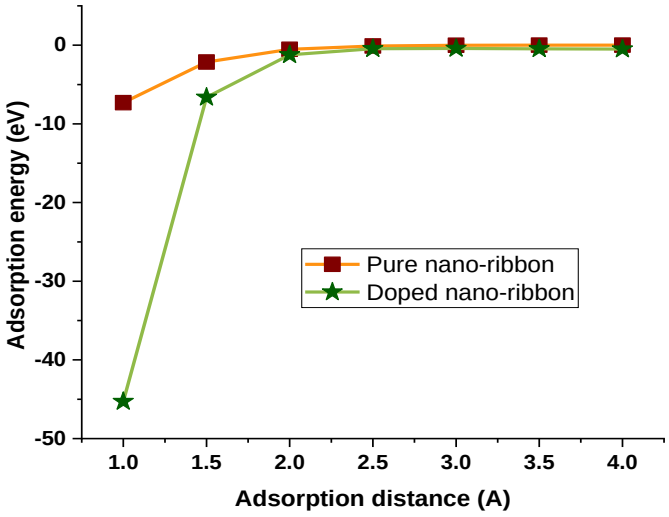

Fig. 2. Adsorption energy curves for systems under study.

4.3. Energy gap

Energy gaps depends on difference energy between HOMO and LUMO value. Results in Table 2 showed that energy gap decreased when interaction increasing, this is suggested to take place because of gas molecule approaches the surface and Van Der Waals formations. Moreover, result revealed that when energy gap decreased in distance near surface of the graphene, the nano-ribbon has high stability [19]. Results showed that for distance far from surface energy gap for adsorbed systems remain at pristine graphene nano-ribbon energy gap, in other hand increasing in energy gap ability of sensing for gases decreased [20]. Energy gap of doped nano-ribbon CH_4 small compared with pure system. Appear energy gaps in this phase because attractive force between CH_4 and surface of nano system. Energy gap in doped nano-ribbon and during adsorption mechanism remain opening. Results show that CH_4 have high reactivity with system under study compared with pure system [21]. Fig. 3 represent energy gap curves for system under study.

Table 2**.** Values of energy gap for systems under study in eV unit.

4	2.532	1.087
Pure nano-ribbon	2.533	
Doped nano-ribbon	1.535	

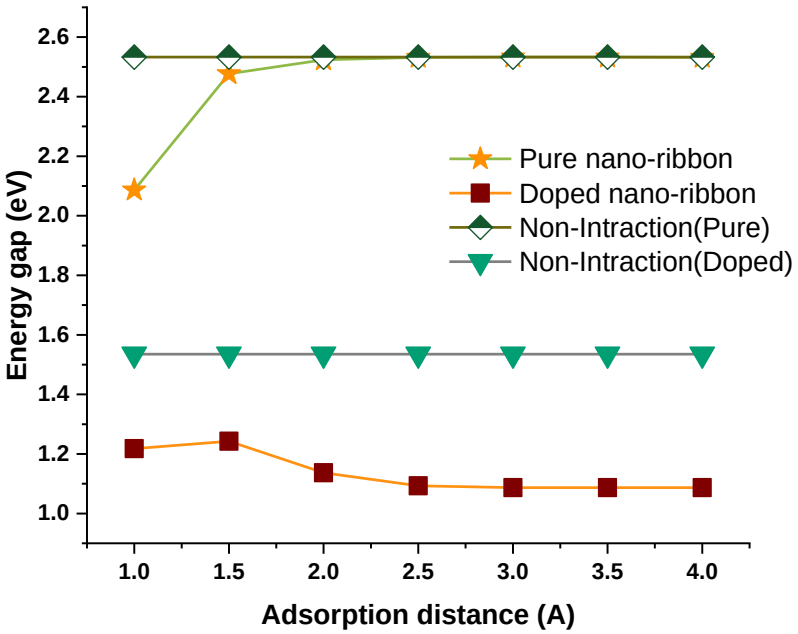

Fig.3. curves of energy gap for adsorption systems.

4.4. FT-IR spectroscopic

In this section study (FT-IR) spectroscopic to determine functional group for graphene before and after adsorption with gas molecule. FT-IR spectroscopy is important tool to determine chemical adsorption by appear the radical of gas adsorbed on surface of graphene nano-ribbon, it calculated using DFT at basis set 6-31G with hybrid function B3YLP. Pure graphene FT-IR analysis for C-H bond appears at 3213 cm^{-1} in stretching vibration mode[22], C-H a skew-symmetric appears on 3192 cm^{-1} of methylene group[22], methylene group appear at 1351cm^{-1} region of FT-IR spectrum approximately from 1349 cm^{-1} for study[22]. For CH_4 adsorbed in pure graphene nano-ribbon, appear new region at wave number (810-828) cm^{-1} and 1458 cm^{-1} resulting from contacted methane molecule on surface of graphene ribbon. For doped nano-ribbon, C-Cu peak appear in very low intensity and wave number was 511 cm^{-1} and this value agreement with previous study in [23]. Carbon metal absorption spectra vary between 350-630 cm^{-1}[24]. CH_4 appear many types of peak related to direction of methane gas. Three new peak appear in spectrum are 1820, 3010 and 3115 cm^{-1} respectively related to CH_4 adsorption [24]. This result proved adsorption of methane gas more acceptable than pure graphene nano-ribbon. Methane can be detecting by this system in all state, in other hand in rest and active state. Also, adsorption process explains that have high effect on carbon metal absorption peaks. Figs. 4 and 5 represent FT-IR spectra for pure and doped nano-ribbon respectively.

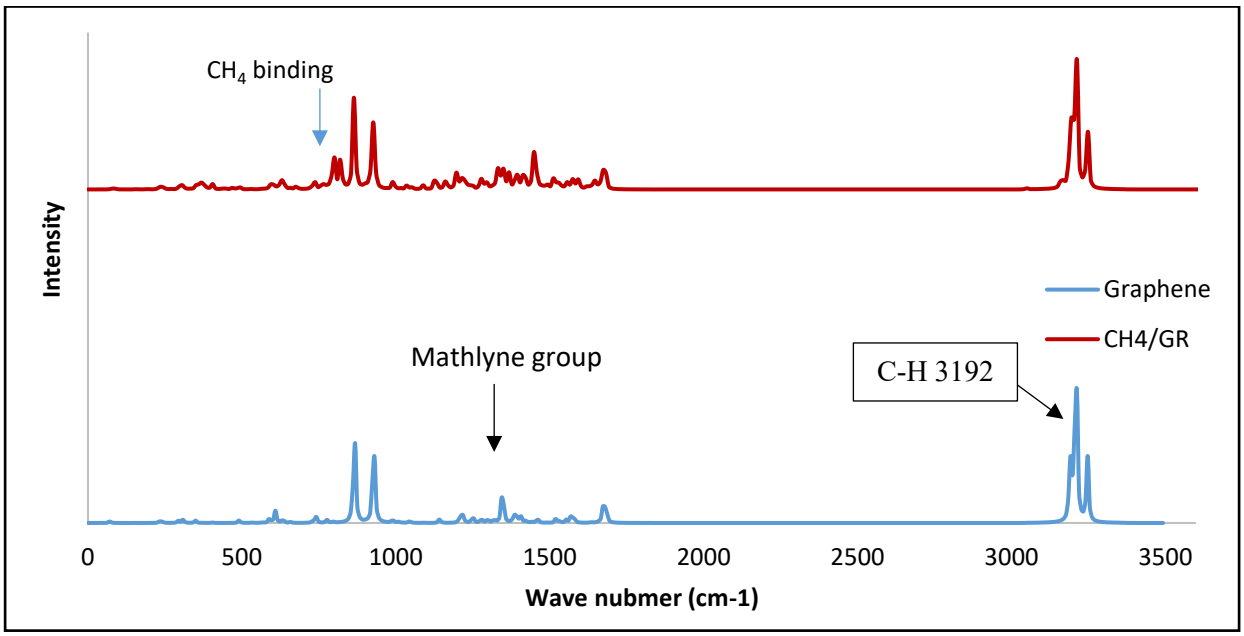

Fig.4. FT-IR spectra of CH_4 adsorbed in pure graphene nano-ribbon.

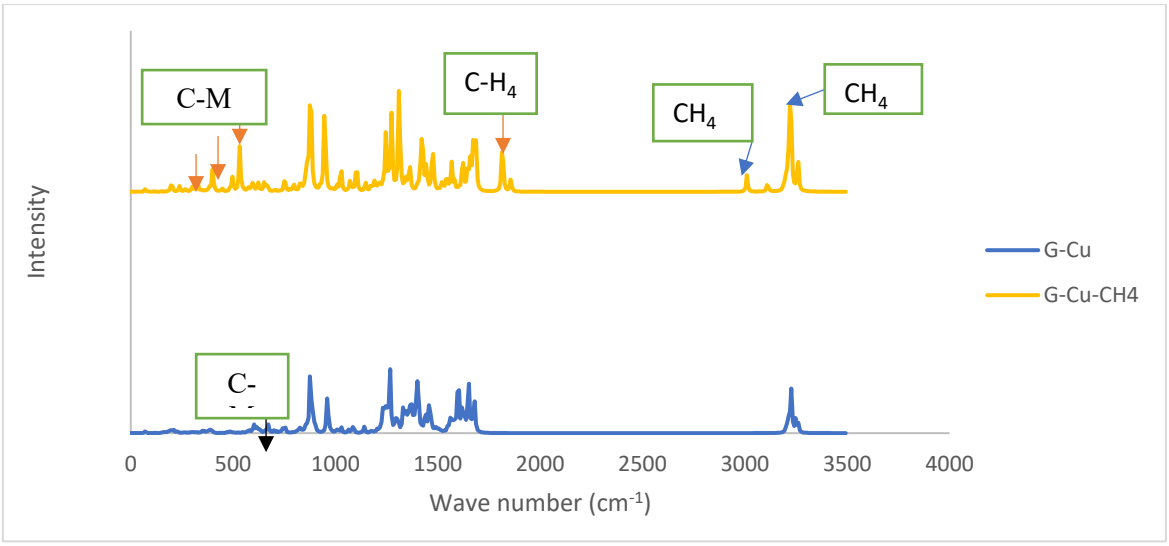

Fig.5. FT-IR spectra of CH_4 adsorbed in doped nano-ribbon.

5. Conclusions

Pure and doped nano ribbon have good relaxation structure, bond length and angle between them has agreements with experimental results. Doped in cupper transition metal medicated electronic, structural and spectral properties of pure graphene nano-ribbon. Methane gas molecule adsorption in pure graphene nano-ribbon was very weak in two types of adsorption, but in doped system result show have high interactivity compared with pure system and kinds of adsorption mechanism. FT-IR spectroscopic used to determine free radical of adsorption gases, doped nano-ribbon sense methane gas in all phases and this result proves that system has high sensitivity compared with pure graphene nano-ribbon.

Study addition of Fe_2O_3 Nanoparticles on Optical Properties for (PMMA-PS) Mixture

Study addition of Fe_2O_3 Nanoparticles on Optical Properties for (PMMA-PS) Mixture

Hussein Ali Hussein Slman and Zaid A. Hasan

Department of physics, College of Education for Pure Sciences, University of Babylon, Iraq

E-mail: hussein.hussein.pure@student.uobabylon.edu.iq

Abstract. In this paper, films of the (PMMA-PS) Mixture doped with Fe_2O_3 nanoparticles were prepared with variable percentage (0,2,4,6) % wt by Drop casting method and at room temperature. The change in optical and structural properties was observed after deformation using a UV-Spectrophotometer and for a range of wavelengths (190 - 1100) nm. The study showed that increasing the distortion ratio led to an increase in the absorbance, absorption coefficient, extinction coefficient, refractive index, real dielectric constant, imaginary isolation constant, and diminishing permeability.

Keywords: Methyl Metha Acrylate, Polystyrene

1. Introduction

Recently, the term nanotechnology has emerged and has been the focus of wide-ranging attention of researchers and has resulted in a great leap in various medical and engineering sciences ... etc.[1]
The term nanocomposites are used to express the product of adding nanoparticles to other ordinary materials to manufacture new materials with distinctive physical properties [2]. PMMA is a colorless transparent thermoplastic that is technically classified as a kind of amorphous glass that is preferred due to its mild properties, ease of handling and handling, and its low cost, but it is fragile under the influence of load, especially under impact strength and is more likely to be scratched than ordinary glass.[3]
In this study, films of PMMA-PS polymeric compounds were prepared by casting technique with the addition Fe_2O_3 nanoparticles in different weight ratios to improve its mechanical and optical properties.

2. Materials and Methods:

Poly Methyl Metha Acrylate with Polystyrene (PMMA/PS) doped with Fe_2O_3 nanoparticles (size: 20- 30 nm, purity: 99.99%) manufacturer (Hongwu nanometer) is to make solution molding mechanism. Mixture the (PMMA- PS/Fe2O3) by ratios (0.2, 0.4, 0.6 wt %) were melted (50ml) of chloroform using a magnetic stirrer, after that the samples dried. Using UV Spectrometer (the equipment from the Japanese company Shimadzu) optical properties of the wavelength range (190-1100) nm were measured. The optical measurements are including, absorbance, absorption coefficient, transmittance, refractive index, real and imaginary insulation constant. All measurements were conducted at room temperature.

3. Results and Discussion:

Optical Measurements

3.1. Absorbance (A)

Defined by the following equation

$$A = log\frac{1}{T} \quad (1)$$

As displayed in Figure 1, the maximum absorbance values are observed at 220nm and decreases with increasing wavelength due to decreasing light energy with increasing incident wavelength according to Planck's law [5].

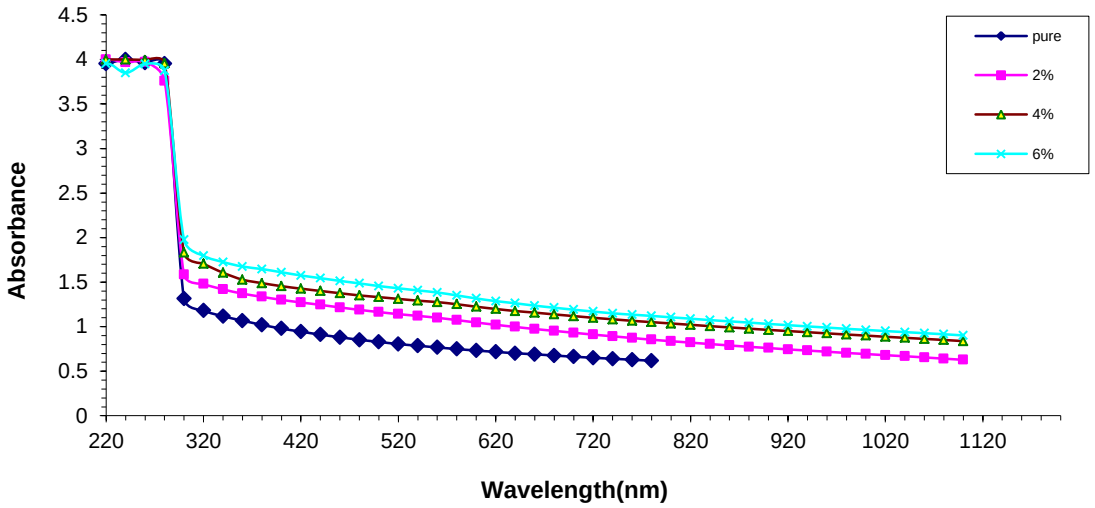

Figure 1. The absorbance spectra of (PS- PMMA- Fe_2O_3) films as a function of incident light wavelength.

3.2. The absorption coefficient (α)

The absorption coefficient was calculated from the relationship below, and the results showed that the absorption coefficient values increased with increasing the added concentrations of Fe_2O_3 nanoparticles as a result of the increase in the incoming light rate according to Lambert's Law [6].

$$\alpha = 2.303\frac{A}{t} \quad (2)$$

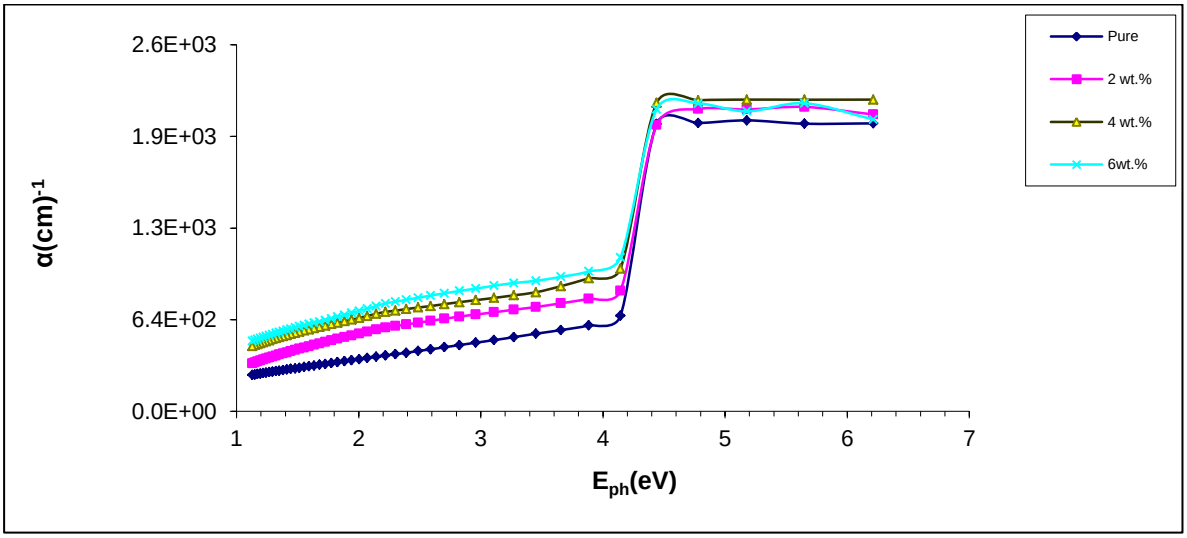

Figure 2. The absorption coefficient of (PMMA-PS –Fe_2O_3 nano) as a function of photon energy.

3.3. Permeability

Figure 3 showed an increase in transmittance with increasing wavelength and percentage. It was observed that the permeability decreased with the increase in the doping because it decreases with increasing the absorbance values, which increase with the increase in the doping rates.

Transmittance (T) is given by

$$T = \frac{I_T}{I_o} \quad \text{.....(3)}$$

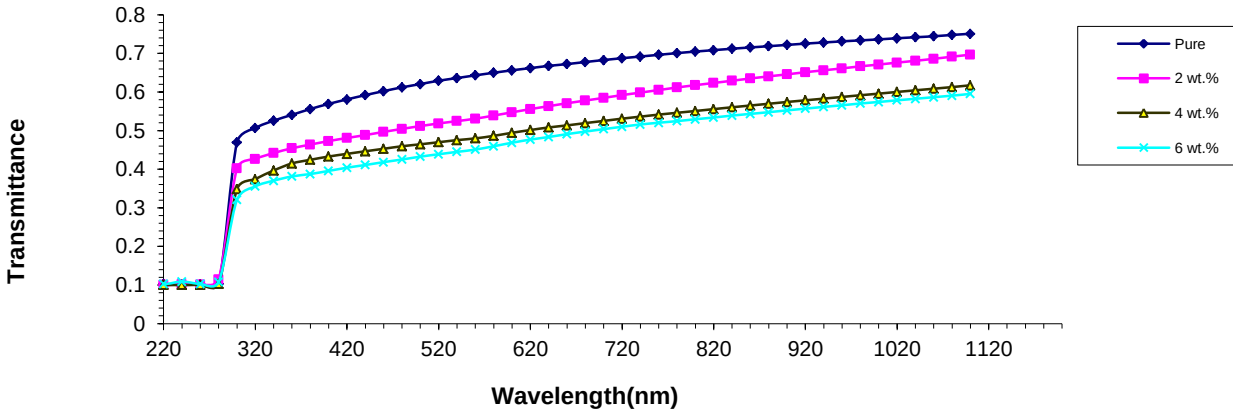

Figure 3. The transmittance spectra of (PS-PMMA–Fe_2O_3nano) blend as a function of incident light wavelength.

3.4. Extinction Coefficient of (k)

Figure 4 shows the change of extinction coefficient as a function of wavelength. It was observed that k decreases with decreased doping, due to an increase in the absorption coefficient with an increase in the ratios of added nanoparticles. The extinction coefficient is high at longer wavelengths and larger doping ratios [7].

$$k = \frac{\alpha\lambda}{4\pi} \quad \ldots\ldots\ldots\

3.6. Dielectric constant (Ɛ)

It is defined as the polarization of charges due to the interaction of radiation and the charges of the medium, and is calculated using the below relations [11]:

$$\varepsilon = \varepsilon_1 - \varepsilon_2 \quad (5)$$

$$\varepsilon_1 = n_0^2 - k^2 \quad (6)$$

$$\varepsilon_2 = 2n_0 k \quad (7)$$

Figure 6 and Figure 7 illustrates the relationship of the dielectric constant as a function of the wavelength as it increases with increasing doped ratios and is consistent with the findings reported in ref.[8].

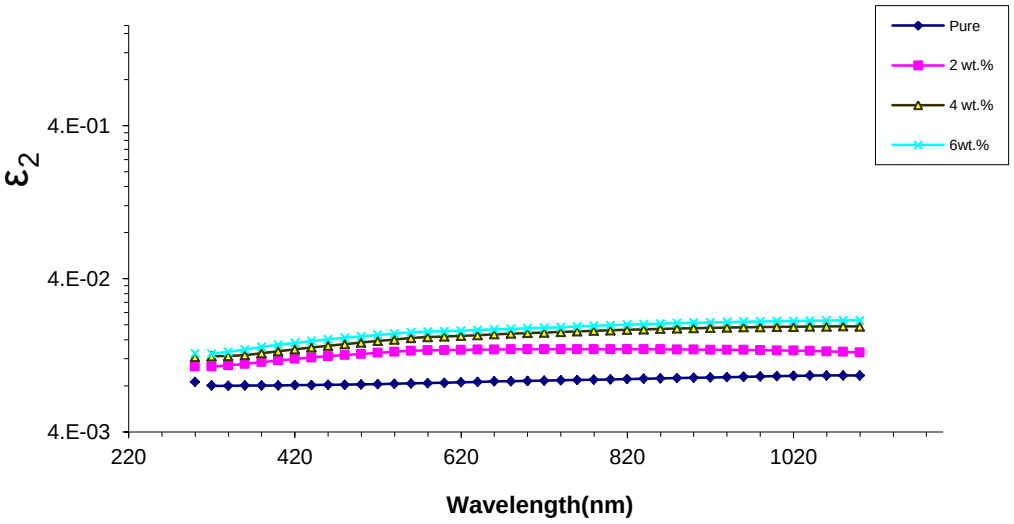

Figure 6. The actual dielectric constant for (PMMA- PS) with Fe_2O_3 nano.

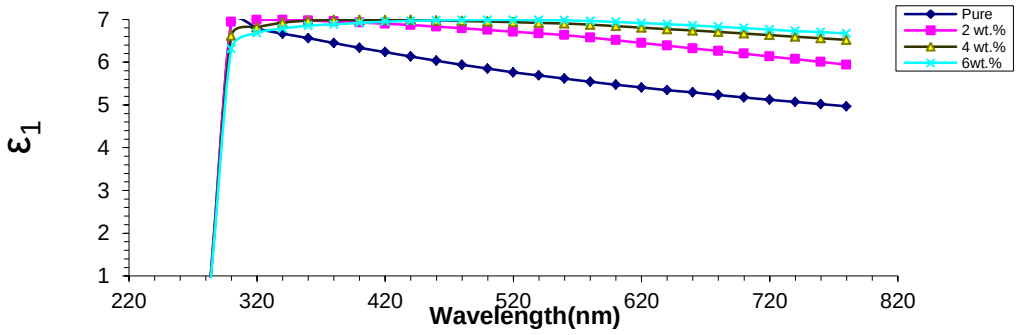

Figure 7. The unreal dielectric constant for (PMMA – PS) with Fe_2O_3 nano.

4. Conclusions

The study is show adding PS to PMMA, obtained a polymeric compound that is bound and cohesive and has a greater impact force, and increasing the ratio of Fe_2O_3 nanoparticles in PMMA-PS compound led to an increase in absorbance, absorption coefficient, real and imaginary dielectric constant, refractive index and decreased transmittance.

Investigating of Charge Transfer in Cu/F8 Using Donor-Acceptor Model due Quantum Transition

Investigating of Charge Transfer in Cu/ F8 Using Donor-Acceptor Model due Quantum Transition

E-mail: Hadi_AlAgealy@yahoo.com

Abstract. In this paper, we study and investigate a simple donor-acceptor model for charge transfer formation using a quantum transition theory. The transfer parameters which enhanced the charge transfer and the rate of the charge transfer have been calculated. Then, we study the net charge transfer through interface of Cu/F8 contact devices and evaluate all transfer coefficients. The charge transfer rate of transfer processes is found to be dominated in the low orientation free energy and increased a little in decreased potential at interface comparison to the high potential at interface .The increased transition energy results in increasing the orientation of Cu to F8.The transfer in the system was more active when the system has large driving force energy and caused fast transfer from the donor to the acceptor and the charge transfer rate dependent on potential and solvents effect.

Keywords: Charge Transfer, Cu/ F8, orientation energy

1. Introduction

The charge transfer at level energy of a molecule has been played a basic role in different areas of physics, chemistry, material science, and biology [1]. Charge transfer was important fundamental process in electronics devices. The charge transfers from the molecule to the solid cross potential at interface. This transfer changes the electronic distribution by rearrangement of molecules and atoms [2]. In recent years, more attention of the charge transfer at interface between two different materials. Field of charge transfer in materials introduced more knowledge to understand and characterize the mechanisms of charge transition through interfaces such that molecule/semiconductor, molecule/molecule and molecule/metal interfaces [3]. The basic concept for describing the electronic transfer in solid contact with liquid has defined by the classical charge transfer theory that introduced by Marcus R. A. in 1992, it's still an actively field research after more than 60 years ago and developed by Rudolph Marcus, Levich, Dogonadeze and Gerischer [4]. The interface of contact organic active with metallic is very an importance to investigated and study electron transfer and determined the efficiency of the metal/ molecule through study the orbital levels of dye alignment with Fermi levels for metal [5]. The characteristic of electronic transfer at metal contact with the organic molecule are depending on the alignment of energy levels of electrons at molecule and the bands levels at metal [6]. In this research the theoretical system Cu/ F8 device include study the charge

transfer and determine the rate of the charge transfer. For Cu/ F8 system, the transition energy, potential and current electronic transfer will be present.

2. Theory

The non- adiabatic rate of electron transfer is [7].

$k_{nd} = \frac{2\pi}{\hbar}|R_c|^2\, WFC$……(1)

Where $\hbar$ is the $\frac{h}{2\pi}$, h is Blank constant, R_c is the resonance coupling of electronic term and WFC is the Franck–Condon weight. However, the Franck–Condon weight $WFC \equiv \boldsymbol{\delta}(E_{\beta_i} - E_{\alpha_i})$,the non-adiabatic rate with summed over all probability of vibrational quantum levels can be written as.

$k_{nd} = \frac{2\pi}{\hbar}\sum_i g(E)\left|\langle\hat{R}_c\rangle\right|^2 \boldsymbol{\delta}(E_f - E_i)$…….. (2)

$g_{(E)}$ is the distribution of electronic density of state and given by Fermi density of state [8].

$g(E) = \frac{1}{1+e^{\frac{E}{k_B T}}}$ ……. (3)

Where$E = E_i - E_F$. Inserting Eq.(3) in Eq.(2)

$k_{nd} = \frac{2\pi}{\hbar}\sum_i \frac{1}{1+e^{\frac{E}{k_B T}}}\left|\langle\hat{R}_c\rangle\right|^2 \boldsymbol{\delta}(E_f - E_i)$…….. (4)

Introduce the total density $\boldsymbol{D}_{(E)}$for all states of system

$k_{nd} = \frac{2\pi}{\hbar}\sum_i \frac{1}{1+e^{\frac{E}{k_B T}}}\left|\langle\hat{R}_c\rangle\right|^2 \boldsymbol{D}_{(E)}\boldsymbol{\delta}(E_f - E_i)$……. (5)

However, the activity density of metal-molecule system is equivalent to $\boldsymbol{\delta}(E_f - E_i)$,then Eq.(5) can be written.

$k_{nd} = \frac{2\pi}{\hbar}\sum_i \frac{1}{1+e^{\frac{E}{k_B T}}}\left|\langle\hat{R}_c\rangle\right|^2 \boldsymbol{D}_{(E)}\boldsymbol{\rho}_a(E)$…….. (6)

Then, active density of states for charge transition interaction is [9]

$\boldsymbol{\rho}_a(E) = \boldsymbol{\rho}_{\mathrm{M}}(\mathrm{E})\frac{l_M}{{d_M}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}$…….(7)

here l_M is the length coupling and $d_M(\frac{cm}{atom})$ is average diameter in lattice for metal. Thus, Eq.(7) and Eq.(6) lead to.

$k_{nd} = \frac{2\pi}{\hbar}\sum_i \frac{1}{1+e^{\frac{E}{k_B T}}}\left|\langle\hat{R}_c\rangle\right|^2 \boldsymbol{D}_{(E)}\boldsymbol{\rho}_{\mathrm{M}}(\mathrm{E})\frac{l_M}{{d_M}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}$……(8)

Due to Drude theory, the density of metal states per electron concentration is [10].

$\boldsymbol{\rho}_{\mathrm{M}}(\mathrm{E}) = (\frac{3}{2E_F})$……(9)

Where E_F is the Fermi energy. Substituting Eq.(9) in Eq.(8) results

$k_{nd} = \frac{2\pi}{\hbar}\sum_i \frac{1}{1+e^{\frac{E}{k_B T}}}\left|\langle\hat{R}_c\rangle\right|^2 \boldsymbol{D}_{(E)}(\frac{3}{2E_F})\frac{l_M}{{d_M}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}$……(10)

the density of state given [11].

$\boldsymbol{D}_{(E)} = \sqrt{\frac{1}{4\pi\Gamma k_B T}}\mathrm{e}^{\frac{-(\Gamma+\Delta E^0)^2}{4\Gamma k_B T}}$ …..(11)

For all electrons in the donor-acceptor interface, we inserting Eq.(11) in Eq.(10) and integrated the results .

$k_{nd} = \frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Gamma k_B T}}(\frac{3}{2E_F})\frac{l_M}{{d_M}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}\int_{-\infty}^{\infty}\left|\langle\hat{R}_c\rangle\right|^2 \frac{\mathrm{e}^{\frac{-(\Gamma+\Delta E^0)^2}{4\Gamma k_B T}}}{1+e^{\frac{E}{k_B T}}}\mathrm{dE}$ ..(12)

Where the $\Delta E^0 = E_F - \mathrm{IE}$.The potential at interface of system is .

$\Delta\mathbf{U} = \frac{(E_F - \mathrm{IE} + \Gamma)^2}{4\Gamma}$ ……..….(13)

The Fermi factors can be simply

$$\frac{1}{1+e^{\frac{E}{k_BT}}}=\frac{e^{-\frac{E}{2k_BT}}}{(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}})}\text{…….,…….. (14)}$$

Inserting Eq.(14) in Eq.(13)

$$k_{nd}=\frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Gamma k_BT}}\,(\frac{3}{2E_F})\frac{l_M}{{d_M}^{2/3}(\frac{6}{\pi})^{\frac{1}{3}}}e^{\frac{-(\Gamma+\Delta E^0)^2}{4\Gamma k_BT}}\int_{-\infty}^{\infty}\left|\langle\hat{R}_c\rangle\right|^2\frac{e^{-\frac{E}{2k_BT}}}{\left(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}}\right)}dE\text{…(15)}$$

The $e^{-\frac{E}{2k_BT}}$ can be expand to .

$$e^{-\frac{E}{2k_BT}}=1-\left(\frac{E}{2k_BT}\right)+\frac{1}{2!}\left(\frac{E}{2k_BT}\right)^2-\frac{1}{3!}\left(\frac{E}{2k_BT}\right)^3\text{ ….. }+\frac{1}{n!}(\frac{E}{2k_BT})^n\text{…… (16)}$$

Then Eq.(15) with Eq.(16) reduced to

$$k_{nd}=\frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Gamma k_BT}}\left(\frac{3}{2E_F}\right)\frac{l_M}{{d_M}^{\frac{2}{3}}(\frac{6}{\pi})^{\frac{1}{3}}}e^{\frac{-(\Gamma+\Delta E^0)^2}{4\Gamma k_BT}}\int_{-\infty}^{\infty}\left|\langle\hat{R}_c\rangle\right|^2\frac{1}{\left(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}}\right)}[1-\left(\frac{E}{2k_BT}\right)+\frac{1}{2!}\left(\frac{E}{2k_BT}\right)^2-$$

$$\frac{1}{3!}\left(\frac{E}{2k_BT}\right)^3\text{ ….. }+\frac{1}{n!}(\frac{E}{2k_BT})^n]dE\text{…… (17)}$$

The Eq.(17) simply to

$$k_{nd}=\frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Gamma k_BT}}\left(\frac{3}{2E_F}\right)\frac{l_M}{{d_M}^{\frac{2}{3}}(\frac{6}{\pi})^{\frac{1}{3}}}e^{\frac{-(\Gamma+\Delta E^0)^2}{4\Gamma k_BT}}\left|\langle\hat{R}_c\rangle\right|^2[\int_{-\infty}^{+\infty}\frac{dE}{(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}})}-\frac{1}{2k_BT}\int_{-\infty}^{+\infty}\frac{EdE}{(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}})}+$$

$$\frac{1}{2!}\left(\frac{1}{2k_BT}\right)^2\int_{-\infty}^{+\infty}\frac{E^2dE}{(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}})}-\frac{1}{3!}\left(\frac{1}{2k_BT}\right)^3\int_{-\infty}^{+\infty}\frac{E^3dE}{(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}})}+$$

$$\cdots\ldots\ldots\frac{1}{n!}(\frac{1}{2k_BT})^n\int_{-\infty}^{+\infty}\frac{E^ndE}{(e^{-\frac{E}{2k_BT}}+e^{\frac{E}{2k_BT}})}]\text{(18)}$$

We solved term by term to get

$$k_{nd}=$$

$$\frac{2\pi}{\hbar}\sqrt{\frac{1}{4\pi\Gamma k_BT}}\left(\frac{3}{2E_F}\right)\frac{l_M}{{d_M}^{\frac{2}{3}}(\frac{6}{\pi})^{\frac{1}{3}}}e^{\frac{-(\Gamma+\Delta E^0)^2}{4\Gamma k_BT}}\left|\langle\hat{R}_c\rangle\right|^2[\pi k_BT+\frac{1}{2!}\left(\frac{1}{2k_BT}\right)^2\frac{(\pi k_BT)^3}{4}+\frac{1}{4!}\left(\frac{1}{2k_BT}\right)^4\frac{5(\pi k_BT)^5}{16}+$$

$$\cdots\ldots\frac{1}{n!}(\frac{1}{2k_BT})^n\beta(\pi k_BT)^{n+1}]\text{(19)}$$

The electronic transfer rate per electronic density of metal $N(E_F)$

$$K_{nd}=\frac{k_{nd}}{N(E_F)}\text{…… (20)}$$

Inserting Eq.(20) in Eq.(19) and taken two term approximation .

$$K_{nd}=\frac{2\pi}{N_M(E_F)\hbar}\sqrt{\frac{1}{4\pi\Gamma k_BT}}\left(\frac{3}{2E_F}\right)\frac{l_M}{{d_M}^{\frac{2}{3}}(\frac{6}{\pi})^{\frac{1}{3}}}e^{\frac{-(\Gamma+\Delta E^0)^2}{4\Gamma k_BT}}\left|\langle\hat{R}_c\rangle\right|^2[\pi k_BT+\frac{1}{2!}\left(\frac{1}{2k_BT}\right)^2\frac{(\pi k_BT)^3}{4}]\text{…… (21)}$$

The transfer energy $\Gamma(eV)$ for charge transfer processes is given by [12].

$$\Gamma(eV)=\frac{q^2}{8\pi\varepsilon_o}(\frac{1}{R}-\frac{1}{2D})(\frac{1}{n^2}-\frac{1}{\varepsilon})\text{…… (22)}$$

where q is charge electron, ε_o is the permittivity of vacuum ,ε and n are the dielectric constant and refractive index of solvent, r is the distance between dye and metal, R is the radius of dye can be estimated from the approach [13].

$$R=(\frac{3M}{4\pi N\rho})^{\frac{1}{3}}\text{…….…….…….…… (23)}$$

where the molecular weight is M , Avogadro's number is N and ρ is the density of material. The driving force energy for charge transfer from donor state to an acceptor state when photons incident on the system is given by .

$$\Delta E=E_{in}-\Gamma(eV)\text{ … … … … … … . … … … … … (24)}$$

Where $E_{in}=h\frac{c}{\lambda}$ incident energy by light, c is speed of light and wavelength λ

3. Results

Based on the theory of charge transfer, we calculate the charge transfer rate in Cu/F8 device according to transfer energy, Fermi energy, ionization energy, coupling constant and potential at interface for two materials. The transfer energy in Eq (22) refers to effect of solvent, molecule and metal.

The charge transfer rate in Cu/F8 device has been studied and calculated using theoretical model for identical state of electrons. The rate expression in Eq. (21) is theoretical tools for study the mechanism and behavior of charge transfer. In general, Eq. (22) could be used to evaluation the transition energy for the system using MATLAB program. The radii of F8 and Cu are estimated using Eq. (23) with inserting the molecular weight M, and mass density ρ for materials (F8 and Cu) from the table (1) in Eq.(23) with Avogadro's constant $N = 6.02 \times 10^{23} \frac{Molecule}{mol}$, the results of radii are show in Table (1) and (2).

Table 1. Physical properties of Cu.

Properties	Cu metal [14]

4. Discussion

Understanding and calculated of charge transition rate at the interface of Cu/F8 is an important key prerequisite for investigated and studied the electronic properties of the Cu/F8 devices. However, the characterize of the mechanisms and charge transfer rates needs to understand the transition energy, energy level alignment, potential, driving force and electronic strength coupling between Cu metal and F8 molecule. This indicate that transition energy is the scale parameters of charge transfer processes. The transition energy in table (3) indicate that the system with Propanonitrile solvent has transition energy 0.402805 eV while the system with 1-bromooctane solvent has transition energy 0.21983 eV, this indicate the system with Propanonitrile is less active to charge transfer compare with other solvents. The gap between the transition energy of solvents between the top solvent and bottom solvent are in range (0.21983 eV to 0.402805 eV), the system with low transition energy enhances more transfer compare with large transition energy because low transition energy acting to forming charge transfer states fastly compare with large transition energy and lead to driving more charge cross from donor to acceptor state. To date, the potential and transition energy of charge transfer interaction between metal and molecules are used to study device structure hasn't been properly characterized.Unlike the driving force energy fore system in table (4) with 1-bromooctane solvent in range 3.9134 to 1.3301eV comparing with Propanonitrile solvent in range 3.7304 to 1.1471eV order, when the driving force energy is large that's indicate the charge will transfer cross interface, there is mean the charge transfer rate is large and potential is small .The Cu/F8 system with solvents fall into two categories, low polarity solvent and high polarity solvents.

Table (5)show the potential energy and transition energy for Cu/f8 devices with solvents , the system has small potential 0.695464 with Propanonitrile and high potential 2.4569 with 1-bromooctane solvents ,this indicate the potential states formed at interface by the π*-orbitals similar in chromophore types forcedly with solvents has low polarity function .This lead to assume that charge transfer happened as well as from the donor state to acceptor state when potential is low , that shown in table (6). Additionally, the charge transfer increased due to increase the electronic coupling of transition interactions to be observed.

5. Conclusions

The calculation of rate gives details on the charge transfer dynamics cross interface. Theoretical calculation of charge transfer rate has described in this account and became a good tool to examine the system before made any devices through recent theoretical calculation of charge transfer rate. Transition energy, driving force with potential are of particular value for limited the slow or fast charge transfer processes through different of individual events dynamical polarity, such as the low

and large transition energy, large transfer for system has more driving force energy from the donor to acceptor, potential dependent of the quantum charge transfer rates, and solvents effect. The theoretical description of the charge transfer at interface created an intuitive scenario that appeals to Cu/F8 devices and gives a clear understanding of the effects of charge transfer characteristic on charge transfer rate, the structure of devices, electrical properties, and charge transfer interactions that occur cross interface.

Abstract. The effects of the energy loss interference of homo and hetero nuclear di-cluster ions on the plasma in both Classic and Quantum Models are used to study of response dielectric function. The present work involves the interest ranges for Inertial Conference Fusion (ICF), Z-Pinch and Plasmas of Tokomak. The approximation of the Quantum Random Phase (RPA) is used, and the individual and collective Bohm-Pines model is calculated and the contribution of each mode will be calculated. For incident cluster ions, we present measurement and comparison of the stopping power for (homo nuclear di-cluster (H-H), (He-He)) and hetero-nuclear di-cluster ions like (He-H) in different plasma concentration and temperature of (ICF, Z-Pinch and TOKOMAK). The result appear the dependence of the interference term $I(r)$ on homo and hetero-nuclear di cluster distance r_{12} and the di-cluster velocity. All equations have been programmed to present the work using FORTRAN-90 and the program has been written for numerical calculations.

1. Introduction:

The interactions of the energy cluster beams with plasma targets were an active area of research in recent years, both experimentally and theoretically since they have a lower current beam density. A weaker beam concentration and a smaller region of energy deposition, in fact, stopping the cluster is more complicated than stopping the atomic ions [1, 2]. The following basic processes include cluster ion interaction with a plasma target in the first step. In collisions with plasma, the molecule loses valence electrons and the molecular structure equilibrium is consequently disrupted because of the ionization of its constituent atoms. The ions will lose their energy because their kinetic energies are transferred to the target. Simultaneously, The repulsion induced by dynamically screened coulomb interaction between the like-charged ions drives a portion of them and the molecular ion will undergo the coulomb explosion path. After the initial break-up of the molecule, further movement of the molecule is followed by electronic target excitations, which display significant interference due to near spatial correlation inside the ions, known as the vicinage effect. This form of interference induced by the structure is designed to produce increasing stopping power for each ion compared to the energy loss of the monomer ion moving at the same speed as long as the inter-ionic distances inside the cluster are smaller than the characteristic length of the electronic excitation [3]. On the theoretical side, two key approaches were suggested to explain the interactions between ions and plasma beams: the dielectric formulation [4, 5] and the collisional approach [6-8]. On the basis of the latter, a further model was described using the Transport Cross-Section (TCS) method [9, 10]. Fermi has introduced a dielectric formalism to explain the energy

loss of charged particles in the medium [4], and the other authors have been further developed [5, 11-13]. This formulation includes the screening effects, in a self-consistent way, along with the individual and collective excitations generated in the medium. [14].The aim of this research is to examine energy loss in detail of homo and hetero-nuclear di-cluster ions in the plasmas varying temperatures and densities. The analysis is expressed in the form of classical collision less plasma dielectric formalism and involves calculation using the approximation of the Quantum Random Phase (RPA) as well. We investigate the stopping of homo-and hetero-nuclear di-cluster ions, obtaining interference effects results and comparing them with previous work [15].

2. Theoretical procedure:

For a charged point particle, Ze and speed v, the expression of average energy loss or stopping power is given by.

$$S \equiv Z^2 S_0 = \frac{2(Ze)^2}{\pi v^2} \int_0^\infty \left(\frac{dk}{k}\right) \int_0^{kv} \omega \, d\omega \; Im\left(\frac{-1}{\epsilon(k,\omega)}\right). \quad (1)$$

where $\epsilon(k,\omega)$ is the Medium's Dielectric Function . Previous authors have provided numerous calculations for plasma stopping power utilizing this technique [14]. The dielectric function can be conveniently parameterized in the case of a classical plasma as [15],

$$\epsilon(k,\omega) = 1 + \left(\frac{k_D}{k}\right)^2 W(\xi) \quad (2)$$

where the plasma dispersion function is $W(\xi)$ [16],

$$\xi = \frac{(\omega + i\gamma)/\omega_P}{k/k_D} \quad ; \quad k_D = \lambda_D^{-1} \quad (3)$$

where (γ) represents the damping. In the limit $\gamma \rightarrow 0$ for collision less plasma, Eq. (3) becomes:

$$\xi = \frac{\omega/\omega_P}{k/k_D}, \quad (4)$$

And therefore Eq. (2) becomes,

$$\epsilon(k,\omega) = 1 + \left(\frac{k_D}{k}\right)^2 W\left(\frac{\omega/\omega_P}{k/k_D}\right) \quad (5)$$

The function $W(z)$ can be expressed as a variable $z = \omega/k\upsilon$ given in Appendix (A). The main parameters of the interaction between particles and plasmas problem are the velocity υ, its particle charge Z, the density of plasman_p, and temperature (T). The inter nuclear distance r_{ij} should be used to describe interference effects as well as the correlated ions. Other interest quantities are the frequency of plasma ω_p, v_T velocity of thermal electrons, and Debye length λ_D defined by atomic units [16-17]

$$\omega_p = \sqrt{4\pi n_p} \;, \; v_T = \sqrt{k_B T} \;, \; \lambda_D = \frac{v_T}{\omega_p} = \sqrt{\frac{K_B T}{4\pi n_p}}$$

where the plasma electron density is n_p and the temperature of the electron is T.

2.1 Stopping power of di-cluster ions

Let us consider di-cluster ions with atomic numbers Z_1 and Z_2, depending on the dielectric formulation, the stopping power of di-cluster ions is given as follows [18]:

$$S_{clus} = \left(\frac{-dE}{dx}\right)(Z_1) + \left(\frac{-dE}{dx}\right)(Z_1) + I(Z_1, Z_2, r_{12}) + I(Z_2, Z_1, r_{12}) \quad (6)$$

where ($\frac{-dE}{dx}$) for Z_1 and Z_2 are given in Eq.(1), $I(Z_1, Z_2, r_{12})$ and $I(Z_2, Z_1, r_{12})$ are the correlated functions of two charges in correlated motion with velocity $\vec{v}$ and inter-nuclear separation $\vec{r}_{12} = \overrightarrow{r_1} - \overrightarrow{r_2}$. The stopping power in Eq. (6) given either during (i) Parallel orientation:

$$S_{clus} = \left[\frac{-dE}{dx}\right] = \frac{e^2}{2\pi^2 v} \int dk^3 \frac{\vec{k}.\vec{v}}{k^2} Im\left(\frac{-1}{\epsilon(k,k,v)}\right) \left[(Z_1^2 + Z_2^2) + 2Z_1 Z_2 \cos\left(\vec{K}, \vec{r}_{12}\right)\right] \quad (7)$$

Or in (ii) perpendicular (random) orientation:

$$S_{clus} = \frac{e^2}{2\pi^2 v}\int dk^3 \frac{\vec{k}.\vec{v}}{k^2} Im\left(\frac{-1}{\epsilon(k,k,v)}\right)\left[(Z_1^2+Z_2^2)+2Z_1Z_2\frac{\sin(\vec{k},\vec{r}_{12})}{\vec{k}.\vec{r}_{12}}\right] \quad (8)$$

Using the variable $\omega = k.v$; $dk^3 = 4\pi\left[\frac{\vec{k}}{\vec{v}}\right]d\vec{k}d\omega$ (9)

Therefore, Eqns. (7, 8) become either

$$\left(\frac{-dE}{dx}\right) = \frac{e^2}{2\pi^2 v}\int_0^k \frac{dk}{k}\int_0^{kv} dww\left[(Z_1^2+Z_2^2)+2Z_1Z_2\cos(\vec{k},\vec{r})\right] \quad (10)$$

Or,

$$\langle -\frac{dE}{dx}\rangle = \frac{2e^2}{\pi v^2}\int_0^\infty \frac{d\vec{k}}{\vec{k}}\int_0^{\vec{k}.\vec{v}} wdw\, Im\left(\frac{-1}{\epsilon(k,w)}\right)\left[(Z_1^2+Z_2^2)+2Z_1Z_2\frac{\sin(\vec{k},\vec{r}_{12})}{\vec{k}.\vec{r}_{12}}\right] \quad (11)$$

The simplest case to be considered here is that of a pair of ions $Z_1 = Z_2 = 1$ in correlated motion, structures that may be obtained by the incidence of diatomic molecules. The study of this case is basic in order to understand more complicated cluster structures. The stopping power of cluster ion is given by [19].

$$S_{cls} = \frac{2e^2}{\pi\upsilon^2}\int_0^\infty \frac{dk}{k}\int_0^{k\upsilon} d\omega\,\omega\,\mathrm{Im}\left[\frac{-1}{\varepsilon(k,\omega)}\right]Z_{cls}^2 \quad (12)$$

where either,

$$Z_{cls}^2 = \left(Z_{i1}^2+Z_{i2}^2\right)+2Z_{i1}Z_{i2}\cos(\vec{k},\vec{r}) \quad (13)$$

$$Z_{cls}^2 = \left(Z_{i1}^2+Z_{i2}^2\right)+2Z_{i1}Z_{i2}\frac{\sin(\vec{k},\vec{r})}{\vec{k}.\vec{r}} \quad (14)$$

Therefore, the stopping power of di-cluster divided into two parts. On the other hand, self-interaction stopping power and correlation interaction stopping power are shown below:

$$S_{self} = \frac{2e^2}{\pi\upsilon^2}\left(Z_{i1}^2+Z_{i2}^2\right)\int_0^\infty \frac{dk}{k}\int_0^{k\upsilon} d\omega\,\omega\,\mathrm{Im}\left[\frac{-1}{\varepsilon(k,\omega)}\right] \quad (15)$$

And correlated part either,

$$S_{corr} = \frac{2e^2}{\pi v^2}\left(Z_{i1}^2Z_{i2}^2\right)\int_0^\infty \frac{dk}{k}\int_0^{kv} dwwIm\left[\frac{-1}{\epsilon(k,\omega)}\right]\cos(\vec{k},\vec{r}) \quad (16)$$

Or,

$$S_{corr} = \frac{2e^2}{\pi v^2}\left(Z_{i1}^2Z_{i2}^2\right)\int_0^\infty \frac{dk}{k}\int_0^{kv} dwwIm\left[\frac{-1}{\epsilon(k,\omega)}\right]\frac{\sin(\vec{k}.\vec{r})}{\vec{k}.\vec{r}} \quad (17)$$

Then the stopping power of di-cluster ions is:

$$S_{cls} = S_{self} + S_{corr} \quad (18)$$

There are some significant differences between correlated motion (di-cluster) and uncorrelated particles. In the simultaneous interaction between the two particles and the medium, these distinctions arise from interference effects. Let us now consider the effects of interference in the energy loss of the di-cluster produced by two particles in the motion at a velocity $\vec{v}$ through the plasma and at inter-nuclear distance $\vec{r}$. The di-cluster stopping power can be expressed as follows: [20, 22]:

$$S = \left(Z_{i1}^2+Z_{i2}^2\right)S_0 + 2Z_{i1}Z_{i2}\,I(k,r) \quad (19)$$

where $I(k,r)$ is an interference function given by:

$$I(k,r) = \frac{2e^2}{\pi v^2}\int_0^\infty \frac{dk}{k}\int_0^{kv} dw.wIm\left[\frac{-1}{\epsilon(k,w)}\right]\cos(\vec{k},\vec{r}) \quad (20)$$

Or

$$I(k,r) = \frac{2e^2}{\pi v^2}\int_0^\infty \frac{dk}{k}\int_0^{kv} dw.wIm\left[\frac{-1}{\epsilon(k,w)}\right]\frac{\sin(\vec{k}.\vec{r})}{\vec{k}.\vec{r}} \quad (21)$$

S_O is the stopping power of single ions defined in Eq. (1).

2.2 Stopping power of homo di-cluster ions:

Let's assume that the two particles have identical charges. $Z_1 = Z_2 = Z$, so that Eq. (19) becomes,

$$S_{dicl} = 2Z^2\left[S_0 + I_{(r)}\right] \quad (22)$$

The predicted limitations of function $I_{(r)}$ and the stopping power of the di-cluster are as follows:

i. for $r \to 0:$ $I(r) \to S_0$ and $S_{cl} \to (2Z)^2 S_0$ (one charge particle of 2Z)

ii. for $r \to \infty:$ $I(r) \to 0$ *and* $S_{cl} \to 2(Z^2 S_0)$ (two independent particles of charge).

Because of an ordinary experiment, the incident di-cluster is randomly oriented in this case. The average interference term can be taken with respect to the angle between $\vec{r}$ and $\vec{v}$, for H-H di-cluster ions, Z=1,

$$I(r) = \left(\frac{2}{\pi v^2}\right)\int_0^\infty \frac{dk}{k}\left(\frac{\sin kr}{kr}\right)\int_0^{kv} wdw\, Im\left(\frac{-1}{\in(k,w)}\right) \quad (23)$$

Using Eq (5) for the classical dielectric function collision less plasma, the integral of the interference term $I(r)$ can be written as follows:

$$I(r) = \frac{2{w_p}^2}{\pi v^2}\int_0^\infty \frac{k^3 dk}{k_D^4}\left(\frac{\sin(kr)}{kr}\right)\int_0^{v/v_T} zdz\left(\frac{Y(z)}{\left\{\left(\frac{k}{k_D}\right)+X(z)\right\}^2+[Y(z)]^2}\right) \quad (24)$$

The integration with the k variability can be carried out analytically after certain algebra; the function $I(r)$ can be expressed as a single integral,

$$I(r) = \frac{2}{\pi}\left(\frac{\omega}{\upsilon}\right)^2\left(\frac{\lambda_D}{r}\right)^2\int_0^{\upsilon/\upsilon_T} zdz\,\mathrm{Im}\left[F\left(z,k_{\max},r\right)\right] \quad (25)$$

where

$$F(z,k_{max},r) = q\{\sin qr\left[Ci\left((k_{max}-q)r\right)+Ci\left((k_{max}+q)r\right)-Ci(-qr)-Ci(qr)\right]+$$
$$\cos qr * \left[\mathrm{Si}\left((k_{max}-q)r\right)-\mathrm{Si}\left((k_{max}+qr)r\right)-2\,\mathrm{Si}-qr\right]\} \quad (26)$$

With

$$q = q(z) = K_D\sqrt{X(z)+iY(z)} \quad (27)$$

Si and Ci are the integrals of sine and cosine. Analytical results for the interference term $I(r)$ in Eq. (25) can now be obtained for low and high velocities. [15]:

2.1 High –velocity approximations:

In the case of ion with velocity $v \gg v_T$, we can distinguish the contribution from the individual and collective types, also the integral $I(r)$ can be calculated by.

$$\mathrm{I(r)} = \left(\frac{\mathrm{w_p}}{\mathrm{v}}\right)^2\left[\mathrm{I_1}\left(\frac{\mathrm{w_p r}}{\mathrm{v}},\frac{\mathrm{r}}{\lambda_\mathrm{D}}\right)\Theta(\mathrm{v}-\mathrm{v_T})+\mathrm{F_1}\left(\frac{\mathrm{v}}{\mathrm{v_T}}\right)\mathrm{I_1}\left(\frac{\mathrm{r}}{\lambda_\mathrm{D}},\mathrm{k_{max}r}\right)\Theta(\mathrm{k_{max}}-\mathrm{k_D})\right] \quad (28)$$

So,

$$I(r) = I^{ind}(r) + I^{coll}(r) \quad (29)$$

The above equations have been calculated numerically by programed the equations using Fortran-90 and writing a program $Diclustr-Classic.for$, and a copy of the program is available with authors.

$F_1\left(\frac{v}{v_T}\right)$ is given by,

$$F_1(x) = \left(\frac{2}{\pi}\right)^{1/2}\int_0^x z^2\exp\left(\frac{-z^2}{2}\right)dz \quad (30)$$

And ,

$$I_1(x,y) = \int_x^y\left(\frac{\sin(z)}{z^2}\right)dz = H(x) - H(y) \quad (31)$$

By defining H(x),

$$H(x) = \left(\frac{\sin x}{x}\right)Ci(x) \quad (32)$$

And in general one can say that:

$$H(u) = \left(\frac{\sin u}{u}\right) Ci(u) \quad (33)$$

For $v \gg v_T$ $(x \gg 1)$, $F_1(x) \equiv 1$ and get

$$I(r) \equiv k_{min}^2 I_1(k_{min}r, k_{max}r) \quad (34)$$

With $k_{\min} = 1/b_{\max} = \omega_p / \upsilon$, Functional dependency of the interference function at high speed. For large r ($k_{max}r \gg 1$) in Eq. (34) the term with $k_{\max}$ can be neglected. With regard to the lowest electron-ion approach distance in the nearest collisions, the inter-nuclear length is sufficiently large, so, the loss of energy is divided into individually and collectively excitation such that the tow ions behave as an individual scattering collision within the range of high velocities $> v_T$. Usually, the participation of collective modes is a small portion of stopping term S_0 . Additionally, the contribution of collective modes becomes very significant in the integration of the interference expression $I(r)$ [23].

2.3 Low- velocity approximations:

Using the estimation $z \ll 1$, where, $z = \omega / k\upsilon_T$, the function of energy loss $Im[-1/\in (k,w)]$ becomes helpful so,

$$Im\left(\frac{-1}{\in(k,w)}\right) = \sqrt{\frac{\pi}{2}}\left(\frac{k}{k_D}\right)^2 \left\{\frac{Zexp\left(\frac{-z^2}{2}\right)}{[1+(k/k_D)^2]^2}\right\} \quad (35)$$

Integrating Eq. (24) one can get the di-cluster at low velocity approximation,

$$\mathrm{I(r)} = \left(\frac{2}{\pi}\right)^{1/2} \frac{1}{3\lambda_D^2} \mathrm{I_2(r/\lambda_D, k_{max}/k_D)} \left(\frac{\mathrm{v}}{\mathrm{v_T}}\right) \mathrm{F_2(v/v_T)} \quad (36)$$

where $F_2(x)$ is given by:

$$F_2(x) = \frac{3}{x^3} \int_0^x z^2 \exp\left(\frac{-z^2}{2}\right) dz \quad (37)$$

And

$$I_2(x,y) = \int_0^y dz\, z^3 \left(\frac{\sin(zx)}{zx}\right)(1+z^2)^{-2} \quad (38)$$

3. Results and discussion

The calculations were made using the exact integral terms given by the dielectric forms. The classical dielectric function and quantum RPA procedure have been applied. Here, we examine the dependence of the interference term $I(r)$ on the while homo nuclear di cluster distance r_{12} and velocity v. For fast velocity, the behaviour of the interference expression I(r) could be seen in figure (3.5a). For corresponding (ICF) conditions of high velocities and big r quantities (with respect toλ_D) I(r) is rapidly tending to zero and it show low vibrational behaviour corresponding to distances. Though, $I(r)$ tends rapidly to zero for low velocities and large r - quantities (with respect to λ_D). It displays elevated vibrations values. For very long distances, there is no oscillatory activity.

Here, with mutual distances greater than λ_D, ions are scattered throughout a large area. Each ion is capable of generate a long range wake field that contributes to the electrical field at the location of all other ions. Constructive or destructive interferences may occur with respect to the characteristics phases of the wake field and result in increasing or decreasing stopping relative to uncorrelated stopping.

Figure (1) shows the variation of correlation function $I(r)$ and correlated stopping power of cluster ions S_{clus} like (a) H-H ICF, (b) He-He ICF and (c) He-H ICF di-cluster ions with atomic di-cluster ions distance r_{12} . The similar patterns of the results in the all cases (a), (b) and (c) suggest the presence of a basic scale rule. The point to be examined below the figures, utilising either a classical value or a quantum value of $k_{\max}$, show a very strong agreement between these results. To discuss the effects of

the atomic distance r_{12}, (1) $r_{12} \leq 3$ the correlation function $I(r)|_{HH} < I(r)|_{HeH} < I(r)|_{HeHe}$ while, the stopping power of di-cluster ions S_{clus}: $S_{clus}(r)|_{HH} > S_{clus}(r)|_{HeH} > S_{clus}(r)|_{HeHe}$ as shown in figure (1). (2) at $r_{12} \to \infty$, i.e $r_{12} \geq 20$, there is no contribution to the correlation function $I(r)$ and correlated stopping power S_{clus}. (3) Between these two regions, cosine or sine function appear in Eqns. (23 and 24) are strongly effect.

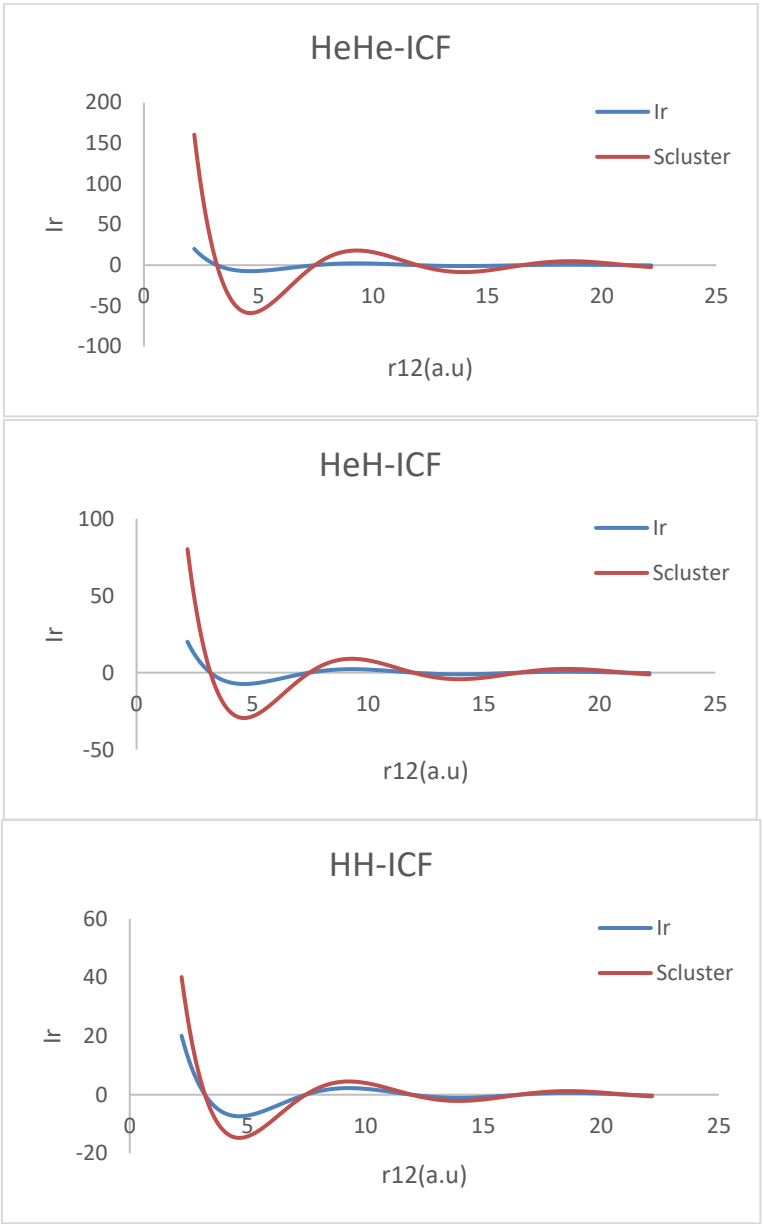

Figure 1. The correlated function term $I(r)$ and correlated stopping power $S_{clus}(r)$ for homo di-cluster ions (a) HH and (b) He-He and (c) hetero di-cluster ions He-H in ICF plasma as a function of inter atomic distances r_{12} were calculated using the classical dielectric function, and the quantum values of k_{max}.

Stopping of Homo and Hetero di-cluster ions:

Let us consider a di-cluster comprising two different forms of heavy atomic ions. For fast heavy ions, a number of electrons are typically carried with an increasing depth of penetration. The charge of the ion fluctuates around a certain value of the balance, which is generally calculated through the form of term:

$$q_i e \approx Z_i e[1-\exp(-\upsilon/\upsilon_{TF}] \quad (39)$$

where, $\upsilon_{TF} = Z_i^{2/3}\upsilon_0$ is the velocity of Thomas-Fermi

The ionic effective charge is usually expressed via the ion charge Z_i and the fractional effective charge of ion γ_i ,

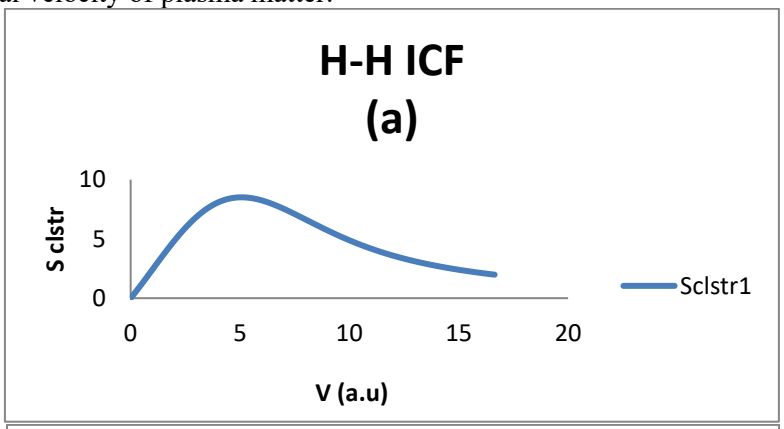
$$Z_{eff} = \gamma_i Z_i \quad (40)$$

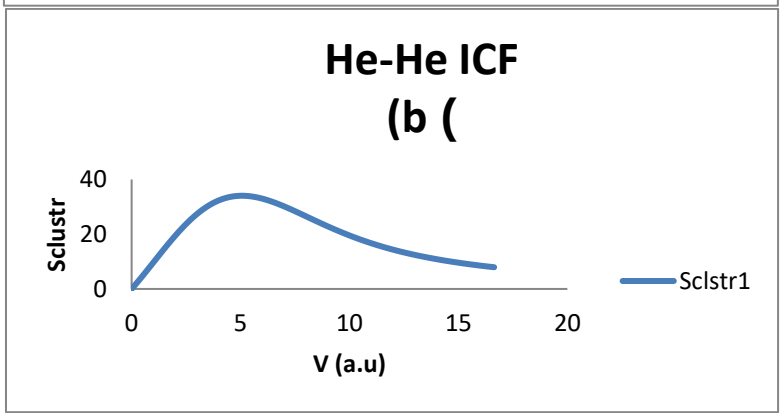
To connect the effective charge with the heavy $H_e - H$ di-cluster ions let the effective charge of two ions are Z^*_{He}, where,

$$Z^*_{He} = Z_{He}\left(1 - e^{-\upsilon_r/Z_{He}^{2/3}}\right) \quad (41)$$

Then, the stopping power of the di-cluster ions of charges Z^*_{He} with atomic number $Z_{He} = 2$ and $Z = 1$ is given in Eqns. (13, 14 and 6).

Three kinds of di-cluster ions have been used in present work, Hydrogen-Hydrogen (H-H), Helium-Helium (He-He) and Helium-Hydrogen (He-H). Figure (2) shows the stopping power for Homo di-cluster ions like (a) H-H, (b) He-He, and (c) Hetero di-cluster ions, and He-H as a function of the velocity in plasma system ICF. Note that the difference in scale percentage between the three systems of di-clusters ions that is why the interaction between incident homo nuclear di-cluster and electron target in ICF more Hetero di-cluster ions because the difference in atomic number of incident ions with the same density and thermal velocity of plasma matter.





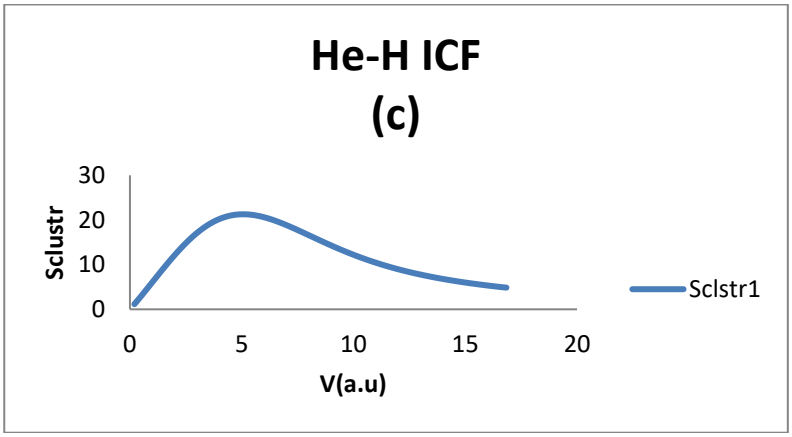


Figure 2. Calculations the stopping power of homo nuclear di cluster for (a) H-H, (b) He-He and (c) Hetero di-cluster ions HeH) in plasma system ICF. As a function of ion velocities.

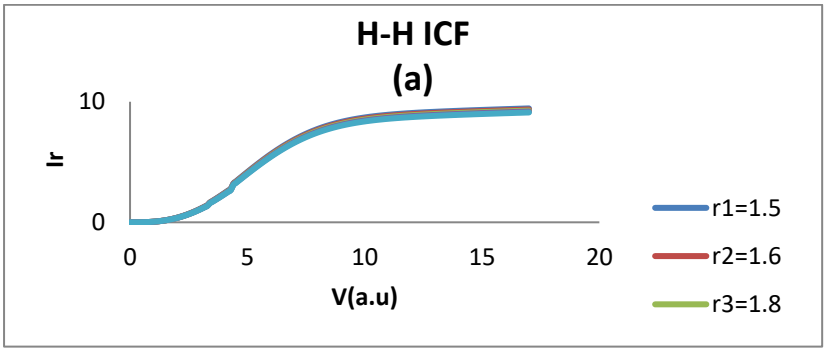
Figure (3) shows that the computations have been made using the exact integral terms given by the dielectric formula, both the classical dielectric function and the quantum (RPA) procedure have been used. We analyse here the dependent of the interference definition I(r) on the hetero nuclear di cluster distance r_{12} and on the di cluster velocity υ. The behaviour of the interference concept $I(r)$ is displayed in figure (3a) for high velocities for the conditions corresponding to the (ICF) at large r values (with respect to λ_D). I(r) tends to zero rapidly and exhibits low vibrational behaviour corresponding to distances, while for low velocities the behaviour of the interference definition I(r) is displayed in figure (3b) for the conditions corresponding to the (Z-Pinch) tends to high oscillatory behaviour corresponding to distances.

Figure (4) shows the movement of hetero nuclear di-cluster (He-H) ion in different plasma systems (ICF, Z-Pinch) and in different distance between hetero nuclear di-cluster for ICF system the folds increase with velocity because of increasing the number of interaction between di-cluster and electron plasma. The effect of intensity and the stopping appear from the number of folds were increased with increasing the density, while for Z-Pinch the folds decrease with velocity because the density is low compare to ICF.



r = 1.50000 1.65000 1.80000 1.95000 2.10000

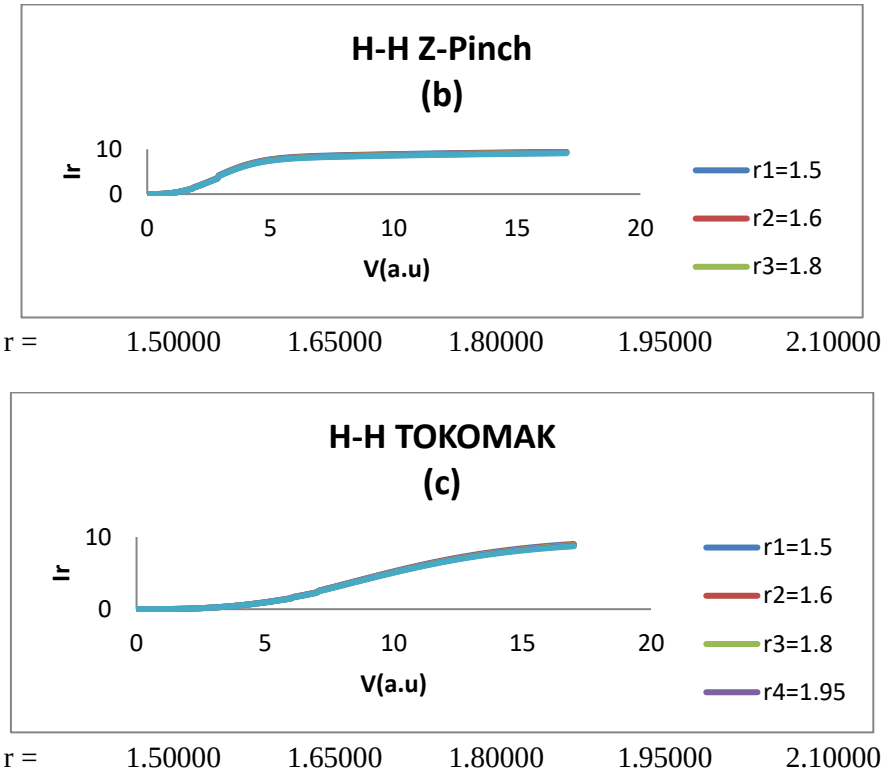


Figure 3. Show movement of di cluster (H-H) in the cases of (a) ICF , (b) Z-pinch and (c) Tokomak system characterized by the distance (r) between di cluster (H-H) .

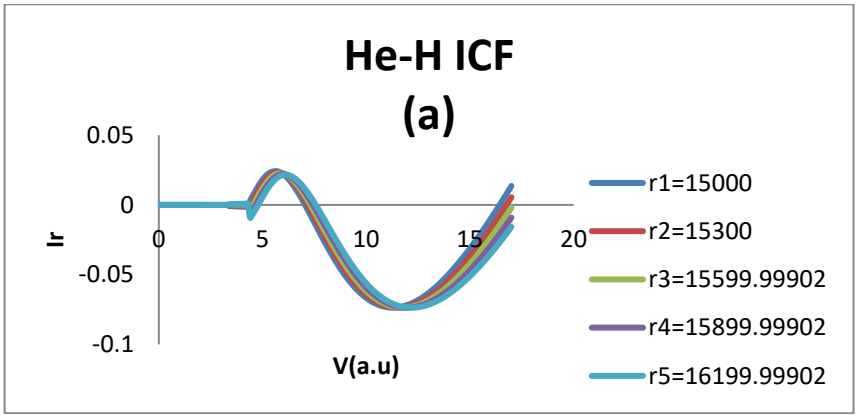

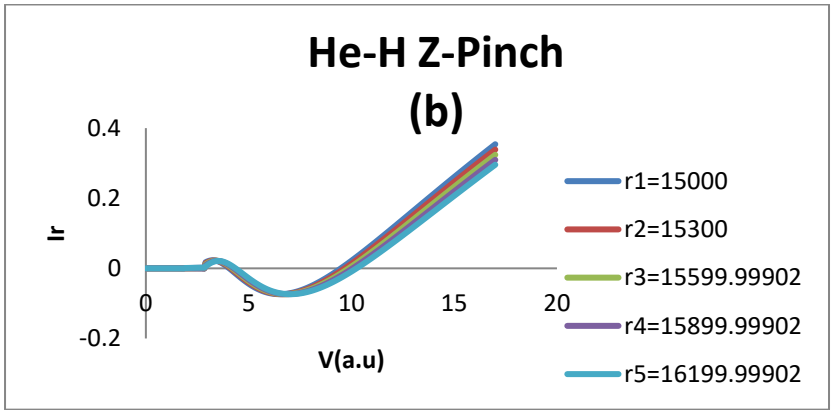

Figure 4. Shows the effect of the movement of hetero-nuclear di-cluster ions (He-H) inside (ICF and Z-pinch) systems plasma in different distance.

4. Conclusion

For different plasma conditions, the loss of energy of di-cluster ions in plasmas was analyzed numerically and analytically, detailed views the effect of the most important factors. The application of a classical dielectric function enables the stopping power and interference terms to be conveniently integrated.

In the case of low velocity, the consequences of interference are only significant if the distances between the two ions are identical or less than the Debye length λ_D. In the case of molecular ions inserted into plasmas, this condition is very well satisfied. In the case of high speeds, the interference function generally scaled with the parameter$r\ w_p/v$. As the value of b_{max} increases with velocity, the effects of interference will become more relevant and large collective effects can be expected.

Appendix (A)

Using the parameter $\omega_p = \sqrt{4\pi n_p}$, $v_T = \sqrt{k_B T}$, $\lambda_D = \frac{v_T}{\omega_p} = \sqrt{\frac{K_B T}{4\pi n_p}}$,

And according to Eq.(2.15), with $\xi = \left(\frac{(\omega + i\gamma)/\omega_p}{k/k_D} \right)$, one can finds

$$\epsilon(k,\omega) = 1 + \left(\frac{k_D}{k}\right)^2 W(\xi) \qquad \text{(A1)}$$

where the plasma dispersion function is $W(\xi)$ [22]

For $\gamma \to 0$ (collisional plasma) the $W(\xi)$ function can be expressed in term of the variable $\xi = \omega / k\upsilon$ as follows:

$$W(z) = X(\xi) + iY(\xi) \qquad \text{(A2)}$$

With

$$X(\xi) = 1 - \xi\ exp\left(\frac{-\xi^2}{2}\right) \int_0^{\xi} dx \exp\left(\frac{x^2}{2}\right) \qquad \text{(A3)}$$

And

$$Y(\xi) = \left(\frac{\pi}{2}\right)^{1/2} \xi\ exp\left(\frac{-\xi^2}{2}\right) \qquad \text{(A4)}$$

Abstract. The aim of this work is to learn the relationship of the stability of (β) emitter isobars with their shape for some isobaric elements with even mass number (A=152 - 162). To reach this goal firstly the most stable isobar have been determined by plotting mass parabola (plotting the binding energy (B.E) as a function of the atomic number (Z)) for each isobaric family. Then three-dimensional representation graphics for each nucleus in these isobaric families have been plotted to illustrate the deformation in the shape of a nucleus. These three-dimensional representation graphics prepared by calculating the values of semi-axis minor (a), major (b) and (c) ellipsoid axis's. Our results show that the shape of nuclides which is represented the most stable isobar in mass parabola are not spherical but they have some deformation in their shape, and need to emit a gamma ray to a chive more stable status and get spherical shape. The stable nuclides, which are determined from mass parabola, are different from the nuclides, which have less value of deformation.

Keywords: Nuclear Binding Energy, Semi Empirical Mass Formula (SEMF), Mass Parabolas, the intrinsic quadrupole moment.

1. Introduction

The minimum part of the elements that keeps the basic features is the atom. An atom is made of a minor massive central called the nucleus; this nucleus is enclosed by orbiting electrons [1]. Nucleus consists of two kinds of separate nucleons (neutrons and the protons) these nucleons having nearly the same mass. Therefore, the binding energy of a nucleus is a dis-continuous function of its mass [2]. Cables of nuclei having similar mass number (A) but unlike in there number of protons (Z) and neutrons number (N) are called isobars. For example, the three nuclei 14C, 14Oand14N are isobars with mass number (A) = 14 [2]. Instability of nuclide causes the radioactivity. Which depends on, the symmetry between the neutrons and atomic number [3].

All nuclei which are unstable decay naturally in several ways. Isobars with a high extra of neutrons profit energy by translating a neutron into a proton. In the case of a surplus of protons, the reverse reaction may occur: i.e., the change of a proton into a neutron. These changes are called β-decays [4]. Beta particles (β) are electrons, which carry a negative or positive charge (e^{-}&e^{+}). In the state of (β^{-}) decay atomic number (Z) increased by one unit. But in the case of (β^{+}) decay the atomic number (Z) will be reduced by one unit. Some nuclei go through a radioactive conversion by taking an atomic electron, generally from K shell, releasing a neutrino in addition to decreases atomic number (Z) by one unit [5].

The deformation in the shape of nuclides arises from the method that valence nucleons arrangement themselves in an unfilled shell, in other words the deformation happens only when both proton and

neutron shells are slightly full. In the group, decay procedure the significant character is shell nuclear deformations. [3]

2. Theoretical Part

2.1. Semi Empirical Mass Formula (SEMF)

Semi Empirical Mass Formula (SEMF) is used to calculate mass, binding energy of nuclei, which is built on Liquid Drop Model (LDM) and originally expressed by C. F. V. Weizsäcker [2]. Then adapted by Bethe and other physician. It is built partly on model and partially on empirical measurement, thus this formula is named Semi Empirical mass formula (SEMF). This formula plays an important part in the advance of nuclear physics and it consists of five forms of energy terms that is, the volume, surface, coulomb, asymmetry and pairing energy along with corresponding five kinds of constants, while modifications have been done to the coefficients over the years, but the arrangement of the formula remains the similar till today. (SEMF) has been prolonged by addition unlike additional terms or been adapted by varying the dependence of several terms on A and Z slightly in an energy to expect the binding energies as nearer to experimental values [6].

The whole containing terms of the energy of (SEMF) takes the formula as below:

$$B.E(A,Z) = a_v A - a_s A^{2/3} - a_c Z(Z-1)A^{-1/3} - a_a\ (A-2Z)^2 A^{-1} \pm \delta A^{-1/2} + \eta \text{------- (1)}$$

Where: a_v, a_s, a_c, a_a, δ and η are the energy coefficients that denote to the volume, surface, Coulomb, asymmetry, pairing and shell energy terms, respectively [7].

One set of this factors is[8]: =15.8Mev, a_s,=18.3Mev, a_c=0.72Mev, a_a=23.2MeV.

$$\text{And } \delta = \begin{cases} +11.2 \text{ MeV for (even N, even Z) .} \\ 0 \text{ for (even N odd Z, or even Z, odd N).} \\ -11.2 \text{ MeV for (odd N, odd Z) .} \end{cases}$$

$$\text{And } \eta = \begin{cases} 3 \text{ Mev (N and Z = magic number).} \\ 2 \text{ Mev (N or Z = magic number and other is odd).} \\ 1 \text{ Mev (N or Z = magic number and other is even).} \\ 0 \text{ (N or Z = no magic number).} \end{cases}$$

2.2. Mass Parabola

One of the maximum uses of semi empirical mass formula (SEMF) is to determine the most stable isobar of a given mass number (A) from beta emission by plotting the binding energy as a function to the atomic number (Z) [9]. The isobars located on the sides of the parabola are not stable, thus to be more stable these nuclides will be decay. Nuclides with low atomic number (Z) side of the parabolic, decay by (β^-)emission toward to the increased of the atomic number (Z_A), but the nuclides with high atomic number(Z) decay in the opposite direction toward to the decreased of the atomic number(Z_A), in this case the decay being either by(β^+)emission or electron capture (EC) [9].

2.3. Minor and major ellipsoid axis

In classical electrodynamics, the simplest model for a non-spherical homogeneous charge supply is a rotating ellipsoid with charge z, major axis(b), and minor axis (a) [10]. To determine small (minor) (a) and large (major) (b) ellipsoid axises from following equations [3].

$$a = \left[\frac{<r^2>}{3}\left(5 - \frac{2\delta}{0.3}\right)\right]^{1/2} \quad (2)$$

$$b = [5 < r^2 > -2a^2]^{1/2} \quad (3)$$

Where:

$< r^2 >$: The mean-squared charge distribution radius average which calculated by:

$$< r^2 >= 0.6\left[1.2A^{1/3}\right]^2 \quad (A > 100) \quad (4)$$

(δ): quadruple deformation parameter denotes to the quantity of a deviation of shape of nucleus from spherical shape, which depends on the value of intrinsic quadruple moment (Q_0) as described in this equation [11].

$$\delta = \frac{0.75 Q_o}{(<r^2>Z)} \quad (5)$$

Where:

Q_0: The intrinsic quadrupole moment.

The electric quadrupole moment (Q_0) determines the deviation of the nuclear charge distribution from spherical balance. So electric quadrupole moment (Q_0) represented one of the important amounts to fix the nuclide form, which is in go associated to the reduced transition probability B (E2)↑:[10]

$$Q_0 = \left[\left(\frac{16\,\pi}{5}\right)\frac{B(E2)\uparrow}{e^2}\right]^{\frac{1}{2}} \quad (6)$$

Depending on the Global Best Fit (GLOBAL) a known of the energy E (keV) of the (2^+) state is wholly that required to make a calculation for B (E2) ↑ (e^2b^2). [12]

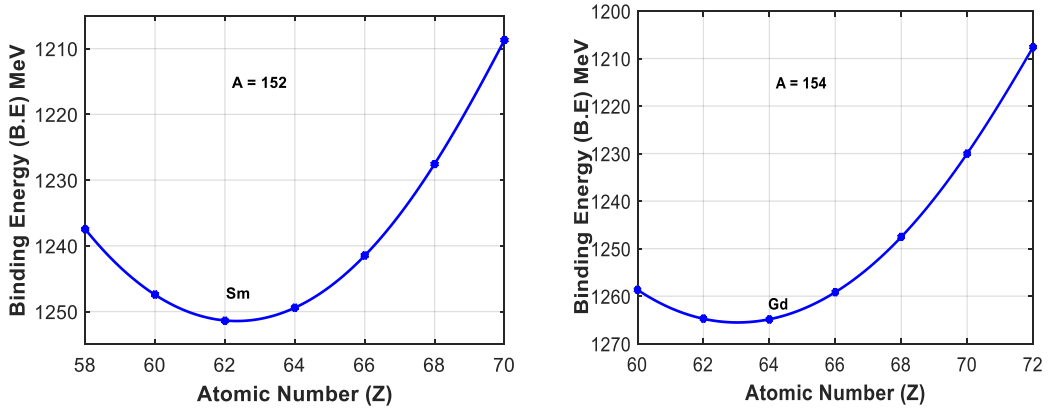
$$B(E2)\uparrow = \frac{2.6\,Z^2}{E_{\gamma_0} A^{\frac{2}{3}}} \quad (7)$$

Where E_{γ_0} is the Gamma ray energy transition in KeV, Z denotes the atomic number, A represents the mass number of a nucleus.

3. Results and Discussion

The study of the relationship of the beta decay stability of isobars with their shape for some isobaric elements with even mass number (A=152 - 162) have been done by calculating the binding energy (B.E) and plotting three-dimensional representation graphics for each nucleus in these isobaric families. The binding energy (B.E) for nuclides under this study calculated by using Semi Empirical Mass Formula (SEMF) eq. (1). The results of binding energy (B.E) were plotted as a function to the atomic number (Z) for each isobar, so we get mass parabolas for different isobars as shown in the fig.1. From this figure the most stable isobars represented the lowest point of the mass parabola (the nuclide with the highest value of binding energy) for each isobar in this study.

Also we can show from Fig. 1 that the value of binding energy is increased by increasing the atomic number (isobars decay by emitting β^- particles) until reaching to the most stable isobar, and then decreased due to distance from the most stable isobar (isobars decay by emitting β^+ particles).



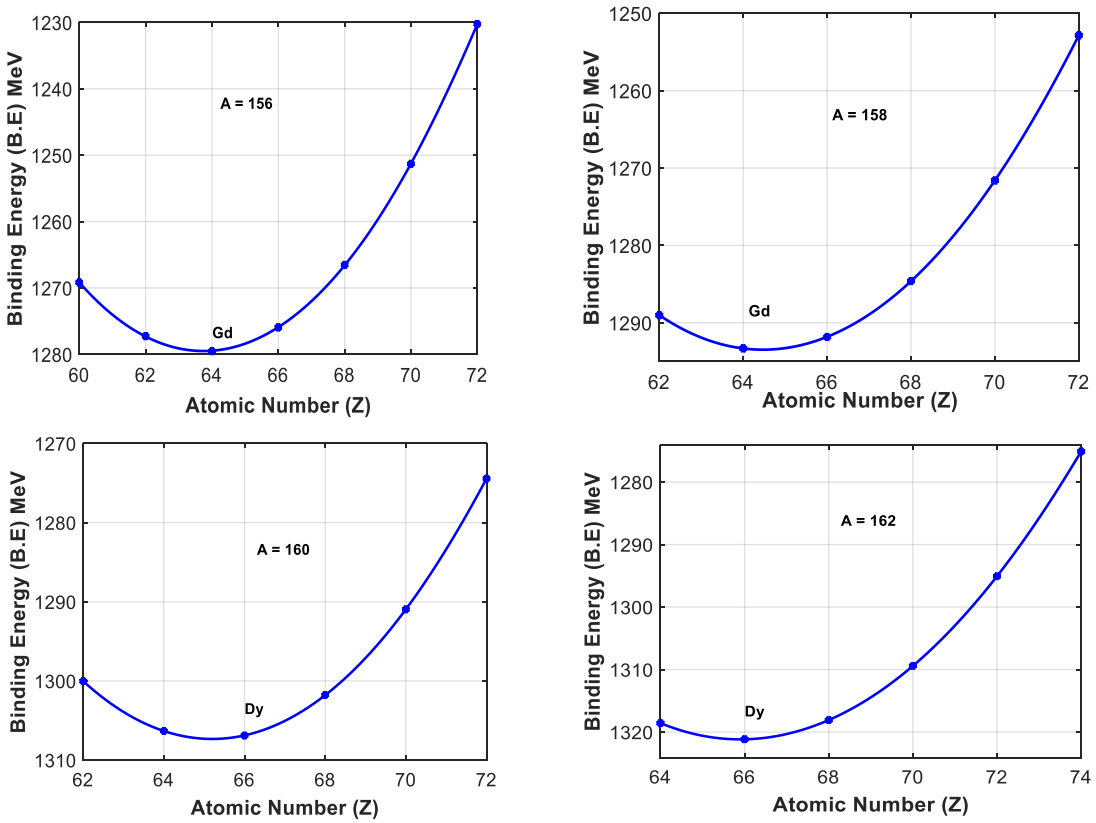


Fig.1. Mass parabolas for isobars with mass number (A=152,154,156,158,160&162).

To plot mass parabolas for isobars with mass number (A=152-162), the values of binding energy (B.E) plotted as a function to the atomic number (Z) for every isobaric family, thus we grow mass parabolas for isobars under this study as shown in the Fig.1.

From this figure we can see clearly that the mass parabola in this range of isobars (A=152-162) un equivalent i.e. the number of isobars which decay by (β+) emission or electron capture (e.c.) greater than isobars which decay by (β-) emission. The reason of that the weighty nuclides have an extra number of protons.

To determine the effect of beta decay stability on the shape of the isobar, plotting the shape of nuclides in (3-D) for each isobar in isobaric families with even mass number (A=152 - 162)have been done, from calculated the values of semi-axis minor (a), major (b) and (c) ellipsoid axis's, i.e. change the degree of deformation of nuclei as a result of the beta emission, the shapes of all nuclides were displayed in Figs. (2-7) respectively.

The semi-axis minor (a), major (b) and (c) ellipsoid axis's are calculated by using equations (2&3) with help of mean-squared charge distribution radius average$< r^2 >$, the quadruple deformation parameter(δ), intrinsic quadruple moment(Q_0), and reduced transition probability B(E2) ↑where the values of these parameters are calculated from equations (4-7) respectively. The values of these parameters presented in Table 1, while the values of the semi-axis minor (a), major (b) and (c) ellipsoid axis's represented in Table 2.

Figs. (2-7) are a three-dimensional representation graphics for the isobar in isobaric family with even mass number (A=152 -162), these figures illustrate the change of the shape for a nucleus with emission of (β^-,β^+).

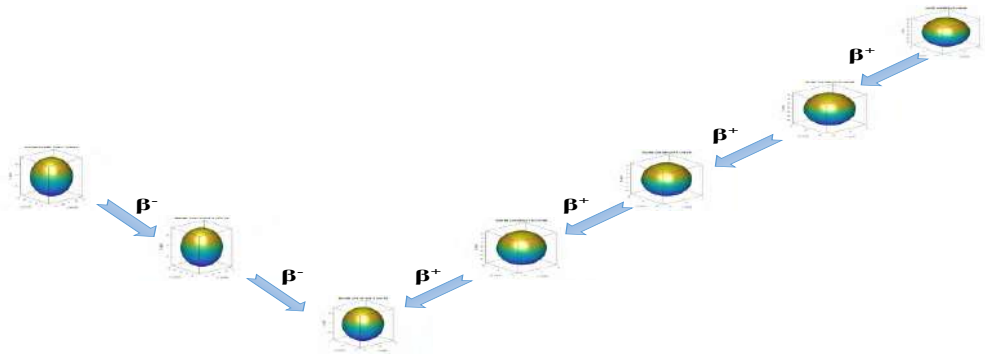

Fig.2. Shape of even-even isobars A=152and (Z= 58, 60, 62, 64, 66, 68 &70).

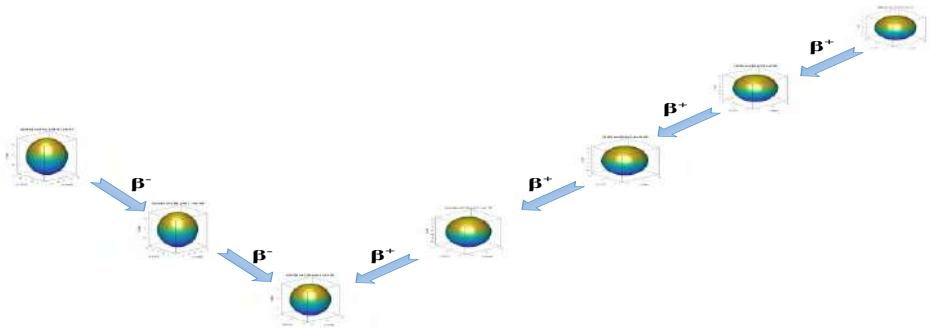

Fig.3. Shape of even-even isobars A=154and (Z=60, 62, 64, 66, 68, 70&72).

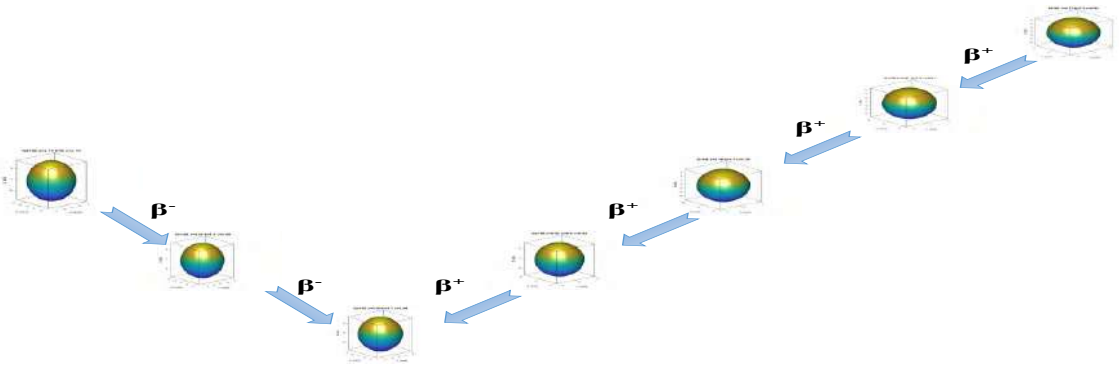

Fig.4. Shape of even-even isobars A=156and (Z= 60, 62, 64, 66, 68, 70&72).

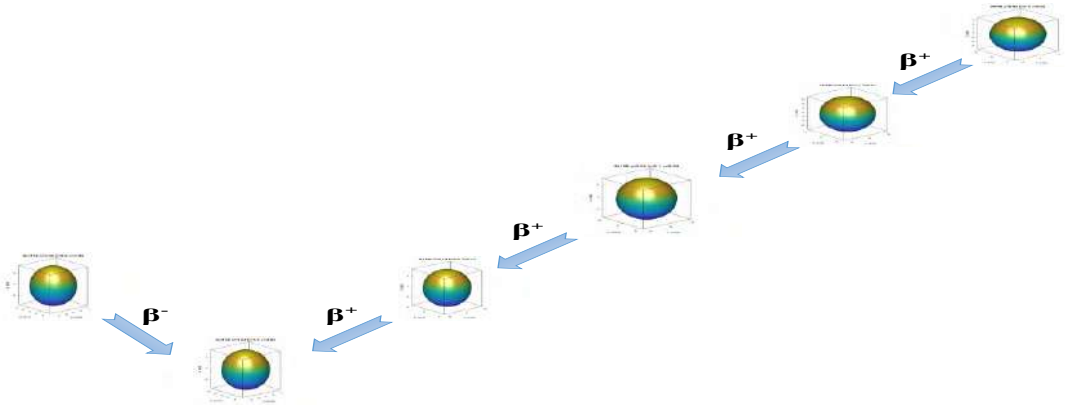

Fig.5. Shape of even-even isobars A=158and (Z= 62, 64, 66, 68, 70&72).

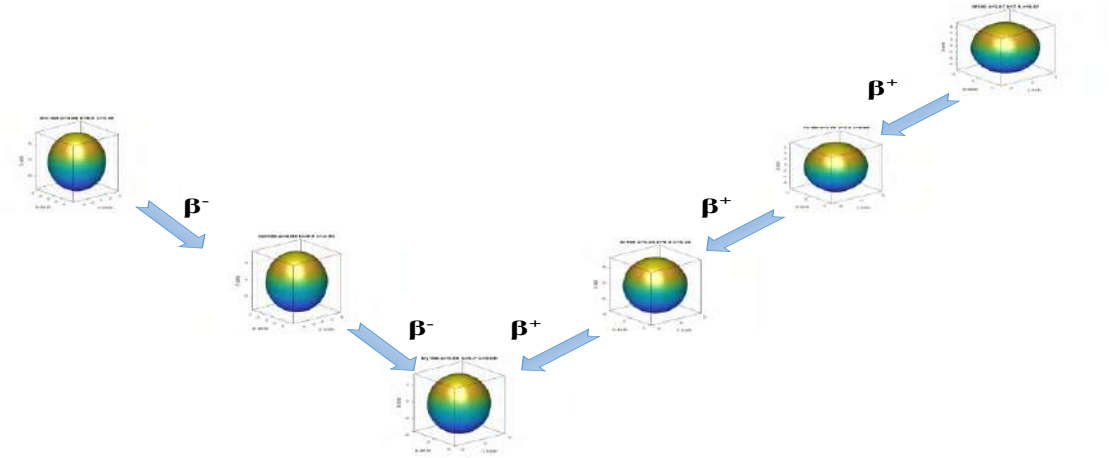

Fig.6. Shape of even-even isobars A=160and (Z= 62, 64, 66, 68, 70&72).

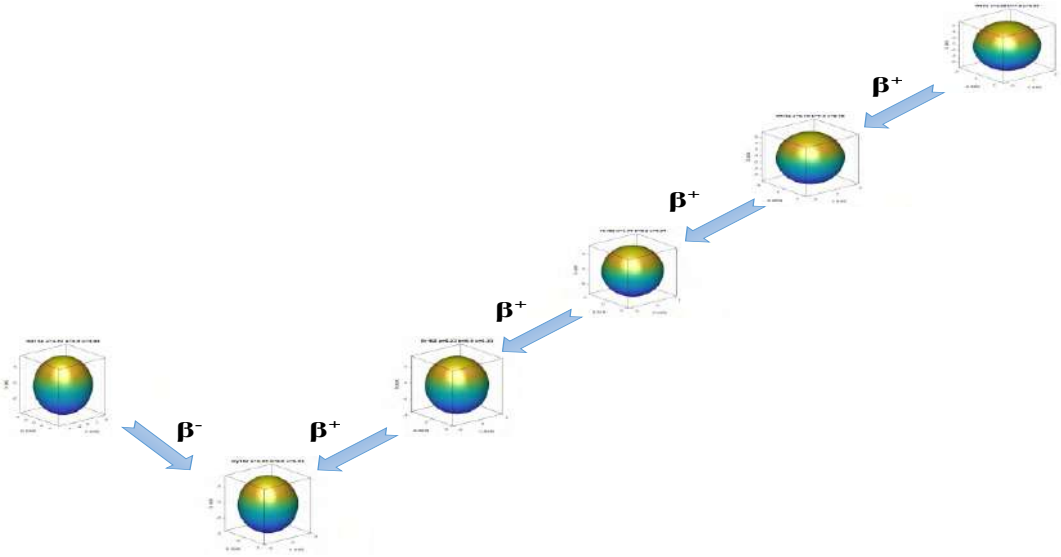

Fig.7. Shape of even-even isobars A=162and (Z= 64, 66, 68, 70, 72&74).

From Figs. (2-7) which represent a three-dimensional shapes for the isobaric elements with even mass number (A=152 - 162) respectively, we distinguished that the shape of nuclides which is represented the most stable isobar in mass parabola (isobaric nuclide with highest value of binding energy) as a result of its decay by emitting (β^-,β^+) particle and electron capture, are not spherical but they have some deformation in its shape. This is due to the fact that the nuclei are not stable by emitting beta particles only (particle loss happens first from radioactive nuclides, maximum of the nucleus excitation energy was a loss if one particle emission, whereas only a minor quantity of angular momentum have been loss in this particle emission. So, gamma-ray release happens to discharge this angular momentum and the residual energy. Only (8–10) MeV are passed out from the excitation energy by every particle produced. So a band of gamma rays are observed until the nucleus be in ground state (stable)).[14] So the most stable isobar needs to emit a gamma ray to move the nucleus from the excited state to the ground state and change its shape to spherical shape.

While depending on Liquid Drop Model (LDM), isobars nuclei under study, which are considered the most stable isobar among the other isobars in same isobaric family because they have the largest binding energy, are not completely stable and therefore do not have a spherical shape.

Also we can note from these figures that the deformation of isobar nuclei decreases with increasing atomic number, as well as for nuclei that have a magic number such as (^{152}Yb &^{154}Hf)neutron magic number equal to(N=82).

Finally, our results show that the stable nuclide which are determined from mass parabola ($^{152}_{62}Sm$, $^{154}_{64}Gd$, $^{156}_{64}Gd$, $^{158}_{64}Gd$, $^{160}_{66}Dy$&$^{162}_{66}Dy$)as a most stable nuclide are different from the nuclides with less value of deformation which are ($^{152}_{70}Yb$, $^{154}_{72}Hf$, $^{156}_{72}Hf$, $^{158}_{72}Hf$, $^{160}_{72}Hf$,&$^{162}_{74}W$) for isobaric elements with even mass number (A=152 - 162) respectively.

4. Conclusions

The results show that the shape of nuclides which is represented the most stable isobar in mass parabola are not spherical but they have some deformation in their shape, and need to emit a gamma ray to a chive more stable status and have the perfect spherical shape**.**

The stable nuclides which are determined from mass parabola are different from the nuclides which have less value of deformation.

Abstract. In this paper, the nuclear structure of the deformed even-even $^{162}_{66}Dy_{96}$ nucleus was studied using the first interacting boson model (IBM-1) to calculate the energy levels E(L) and the transitional energy (E_γ). The energy bands, as well as the quadrupole moment (Q_L) can be calculated to know the shape of the nucleus and the moment of inertia model, energy levels E(L), transitional energy (E_γ) and the bands intersection. The current study showed that at dynamic symmetry SU (3), there is no effect of inertia moment on the shape of the rotational nuclei due to the absence of the phenomenon of back bending that belongs to this dynamic symmetry, through calculating the energy levels ratios found that $^{162}_{66}Dy_{96}$ nucleus belongs to the rotational dynamic symmetry SU (3). A comparison of the available practical results with the results calculated by (VAVM) and (IBM-1) showed that the (VAVM) model are better than the results calculated by (IBM-1).

Keywords: Nuclear structure, Intersection, bosons, moment of inertia.

Introduction

Nuclear physics has had vast quantities of theoretical and experimental energy levels data and information related to the nuclei due to many researchers tried to penetrate into these nuclei or because of the attempt to disassemble these nuclei into their various components, so it has become the duty of nuclear physicists to develop a nuclear model, which is the first step to understand the observed and measured data, relate them and draw conclusions. In spite of the great success achieved by many of the proposed nuclear models in linking data and explaining the nuclear properties, they did not reach the stage of adopting a "one" model, that is, a comprehensive unified theory that can explain everything related to the nuclei in terms of structure and interactions. The most important basic nuclear models proposed to describe the interaction between nucleons and are currently applied are the shell model, the liquid drop model and the collective model. Each of these models is based on a set of assumptions and may be useful. Within certain limits, it can interpret a "specific" range of experimental energy levels data, but it may fail when applied to data outside that range. For example, the "shell model is appropriate" if it is assumed that the interaction between nucleons is a weak interaction, while the liquid drop model or the collective model is used to describe the strong interactions between nucleons, researchers (Arima and Iachello) in 1974 [1] presented a new "nuclear" model called the first Interacting Bosons model This model relied in many aspects on group theory. It is a system of bosons (L = 2) s, (L = 0) d interacting with each other. This model (IBM-1) does not distinguish in its first formula between protons and neutrons bosons.

IBM-1 model is one of the important subjects which use for the purpose of studying some nuclear properties of each odd -mass or even-mass nuclei .in this model we deal with the nucleus with even numbers both of neutrons and protons, i.e. the nuclei (even-even) as a system of neutrons or proton bosons the calculations resulting from this model have shown that there is agreement with practical experiences and the first interacting boson model has had a widely success in describing the fine structure of the nuclei, especially at low energy level*s*[2] . And the interacting boson model builds on the boson holes inside a nuclear closed shell or the interacting valance boson particles outside a closed shell.

N is dependent on the number of active nucleon or(hole) pairs outside the closed shell and the total number of bosons can be calculated by adding the number of proton pairs with the number of neutron pairs that can be their written in the following equation [3]:

$N = n_s + n_d$ ……(1)

Where : n_s is the number of s-bosons

n_d: the number of d-bosons.

The Hamiltonian operator in (IBM-1)

The most appropriate syntax for the operator of the Hamilton function is the formula postulated by Arima and Iachello [4,5] and Iachello [6]

$$\hat{H} = \varepsilon_s(\hat{s}^{+}\hat{s}) + \varepsilon_d(\sum_m \hat{d}^{+}\hat{d}_m^{\sim}) + \sum_{L=0,2,4}\frac{1}{2}(2L+1)^{1/2}C_L\left[\left(d^{+}d\right)^{(L)}\left(\tilde{d}\,\tilde{d}\right)^{(L)}\right]^{(0)}$$

$$+V_2\left[\left(\hat{d}^{\dagger}\hat{d}^{\dagger}\right)^{(2)}\left(\tilde{d}\,\tilde{s}\right)^{(2)} + \left(s^{\dagger}d^{\dagger}\right)^{(2)}\left(\tilde{d}\,\tilde{d}\right)^{(2)} + \left(\frac{1}{2}\right)^{1/2}V_0\left[(\hat{d}^{\dagger}\hat{d}^{\dagger})^{(0)}\left(\tilde{s}\,\tilde{s}\right)^{(0)} + \left(\hat{s}^{\dagger}\hat{s}^{\dagger}\right)^{(0)}\left(\tilde{d}\,\tilde{d}\right)^{(0)}\right]^{(0)}\right]$$

$$+U_2\left[\left(d^{\dagger}d^{\dagger}\right)^{(2)}\left(\tilde{d}\,\tilde{s}\right)^{(2)}\right]^{(0)} + \left(1/2\right)U_0\left[\left(\hat{s}^{\dagger}\hat{s}^{\dagger}\right)^{(0)}\left(\tilde{s}\,\tilde{S}\right)^{(0)}\right]^{(0)} \quad \text{.....(2)}$$

Where ($s^{\dagger}, d^{\dagger}$) and ($\tilde{s}, \tilde{d}$) are creation and annihilation operators for s- and d-bosons, respectively. The effect of the Hamiltonian function in equation (1) includes two parameters describing a single particle and The relationship between energy levels E(L) parameters describing the two interacting particles represented by C_L(L=0,2,4) and four parameters describing the two interacting particles, represented by U_L (L = 0, 2), V_L (L = 0, 2), and all of these parameters depend on the number of N bosons equal to ($n_s + n_d$). The equation (1) can be written in several formulas, but the most popular one is the formula [4.5]:

$$\hat{H} = \varepsilon\hat{n}_d + a_o(\hat{P}^{\dagger}.\hat{P}) + a_1(\hat{L}.^{\dagger}\hat{L}) + a_2(\hat{Q}^{\dagger}.\hat{Q}) + a_3(\hat{T}_3^{\dagger}.\hat{T}_3) + a_4(\hat{T}_4^{\dagger}.\hat{T}_4) \quad \text{……(3)}$$

where $\hat{n}_d$, $\hat{p}$, $\hat{L}$, $\hat{Q}$, $\hat{T}_3$ and $\hat{T}_4$ are the total number of d-boson, pairing, angular momentum, quadrupole, octoupole and hexadecapole operators, respectively

Since ($\varepsilon = \varepsilon_d - \varepsilon_s$) represents the difference between the energy of the bosons (d, s), and for ease it was considered that the energy of the s boson is equal to zero (ε_s = 0) and that

$$\left.\begin{aligned}
&\hat{n}_d = (\hat{d}^\dagger . \tilde{\hat{d}}) \\
&\hat{P} = 1/2(\tilde{\hat{d}} . \tilde{\hat{d}}) - 1/2(\tilde{\hat{s}} . \tilde{\hat{s}}) \\
&\hat{L} = \sqrt{10}[\hat{d}^\dagger \times \tilde{\hat{d}}]^{(\ell)} \\
&\hat{Q} = [(\hat{d}^\dagger \times \tilde{\hat{s}}) + (\tilde{\hat{s}}^\dagger \times \tilde{\hat{d}})] - \frac{\sqrt{7}}{2}[\hat{d}^\dagger \times \tilde{\hat{d}}]^{(2)} \\
&\hat{T}_3 = [\hat{d}^\dagger \times \tilde{\hat{d}}]^{(3)} \\
&\hat{T}_4 = [\hat{d}^\dagger \times \tilde{\hat{d}}]^{(4)}
\end{aligned}\right\} \quad ..(4)$$

The parameters a_0 ..... a_4, they express the strength of the interaction of the pairs, angular momentum, electric quadrupole, octaloupole, hexadecpole are among the bosons, respectively.

The electric quadrupole moment (Q_L)

Electric quadrupole moment **(Q_L)**is defined as the amount of deviation from a symmetric spherical distribution with respect to the nuclear charge within the nucleus. The quadrupole electric moment takes the dimensions of the area and it is measured in barns unit or square meters unit (1barn = $10^{-28}\ m^2$). The shape of the nucleus can be determined by relying on the value of **(Q_L)**where the shape of the nucleus is spherical at (Q = 0) and the shape of the nucleus is deformed prolate at (Q> 0) or is deformed oblate at (Q <0). To derive the electric quadrupole moment values , can be use the values of B (E2, Li→L$_f$), as shown in the following equation: [7,8,9]:

$$\mathrm{Q_L} = [16\pi/5]^{1/2}[\mathrm{L}(2L-1)/(2L+1)(L+1)(2L+3)]^{1/2}[B\big(E2, L_i \rightarrow \quad \ldots\ldots\ldots(5)$$

Where B (E2) is the electric transitions probability, L represents the angular momentum, L $_i$ is the initial angular momentum, L $_f$ is the final angular momentum**.**

Variable Anharmonic Vibrator (VAVM) Model

The two scientists Bonatsos D. and Klein A. in (1984) [10] suggested another new model called (VAVM) model is depend on the (GVMI) model by making the basic functions of the angular momentum (L) and the variable L(L-2). The (VMI) model failed to provide adequate results for some experimental energy levels measurements, where (VAVM) model gave good results in the regions SU(3), SU(5), O(6).

The Energy Band Intersection

The energy band intersection means that the moment of inertia with respect to a certain energy level in any band like (γor β) intersects, or takes the place of any energy level in any other band as a band (g). Bands intersection characteristic consider as an important characteristic for the purpose of studying the bending back phenomenon [11] which occurs between any two bands that have the same spin and but they differ in energy and moment of inertia.

Results and discussion

In this research, the properties of the nucleus $^{162}_{66}Dy_{96}$ are studied such as the electric transitions probability B(E2), energy levels E(L) and transitional energy E_γ and by energy bands (g, γ,β) these levels were classified and the behavior of the nucleus $^{162}_{66}Dy_{96}$ must be determined to be able to choose the parameters of the Hamilton function the equation (2) for the purpose of studying nuclear properties and found that the nucleus $^{162}_{66}Dy_{96}$ belongs to the SU(3) symmetry by comparing the ratios of practical energy values with the ratios of ideal energy values and the values of energy levels are calculated in the IBM-1 model using (IBM. For) program the Written with Fortran language through the Input File (BOS. INP), which contains seven parameters the shown in Table (1), the values of these parameters are determined by matching the values of practical energy levels with theoretical energy level values while

the values of energy levels are calculated in the VAVM model using (VAVM. For) through the input file (PAR. INP), which contains The relationship between energy levels E(L) parameters are : ($\vartheta_0 / \hbar^2$) measured by $(MeV)^{-1}$ *unit* ,C measured by $(MeV)^3$ *unit* and E_K measured by(MeV) unit , where E_k represents the energy of the head of the band in the ground state band (G-band) equals zero while in the β- band equals the angular momentum energy 0^+ for the excited level, but in the gamma band (ɤ-band) the value is variable and by matching the practical values with the theoretical values calculated in the PROGRAM (IBM-1) the values of the parameters shown in table (2) were chosen when the less value of the χ squared (chi-squared) is obtained from the following equation:

$$\chi^2 = \frac{(E_{Cal} - E_{\exp})}{E_{Cal}^2} \quad \ldots\ldots\ldots\ldots\ldots(6)$$

Figure (1) shows the relationship between E(L) practical energy level values compared with theoretical energy level values of the two models (IBM-1,VAVM) for ground state band as a function of angular momentum of a nucleus ($^{162}_{66}Dy_{96}$) and it was noted from the figure that there a quite match between practical energy level values with the values of theoretical energy levels calculated according to the two models(IBM-1,VAVM) for (L≤10) either the values of theoretical energy levels calculated by the (IBM-1)model do not match to the values of practical energy levels for(L>10) because the first interacting boson model do not distinguish between the neutron bosons N_π and the proton bosons N_v, and also because the first interacting boson model did not succeed in calculating the excited energy levels, while the values of energy levels calculated by (VAVM) model with the values of practical energy levels for (L>10) are still fully matched , and this match was the result of better selection of the three input parameter ℓ_0, C and E_K through the input file (PAR. INP) ,and also because the (VAVM) model distinguish between the neutron bosons N_π and the proton bosons N_v . And it was noticed from the figure is that the values of energy levels calculated by the (VAVM) model gave a better match with the values of practical energy levels than the values of theoretical energy levels calculated by the(IBM-1) model and this was the result of the optimal choice of the input parameter values through the input file (PAR. INP).

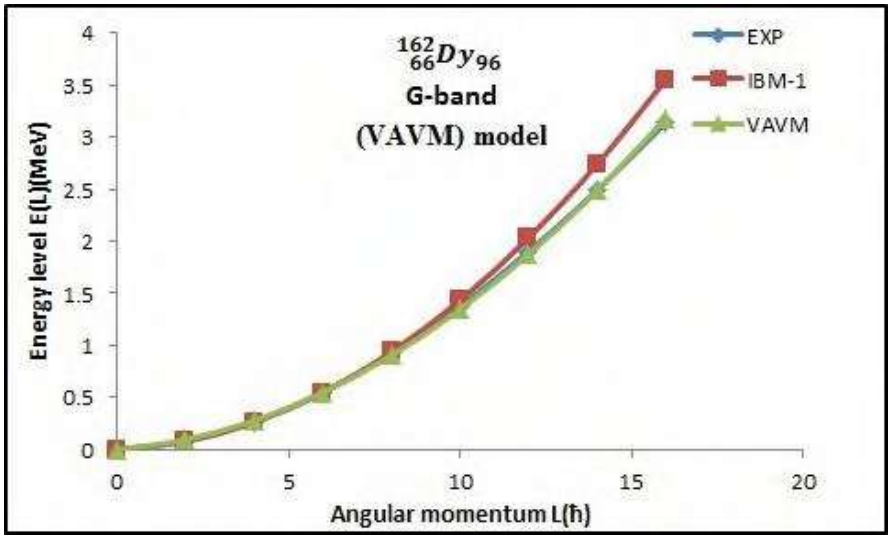

Figure 1. The relationship between energy levels E(L) calculated IBM-1,VAVM and experimental energy levels E(L)versus L for g-band

Figure(2) shows that IBM-1's theoretical energy level values are fully matched, with the gamma -band practical energy level values for (L≤8), the reason for the match is that the first interacting boson model is very successful in calculating low energy levels, either for(L>8) where there is no match between the values of the theoretical energy levels calculated by the(IBM-1) model with the values of the practical energy levels, and a mismatch because the first interacting boson model do not distinguish between the neutron bosons N_π and the proton bosons N_ν, and also because the first interacting boson model did not succeed in calculating the excited energy levels, while all the values of the theoretical energy levels calculated by the (VAVM)model are fully matched with all the practical energy level values for(L>8), and this match was the result of better selection of the three input parameter ℓ_0, C and E_K through the input file (PAR. INP) ,and also because the (VAVM) model distinguish between the neutron bosons N_π and the proton bosons N_ν .

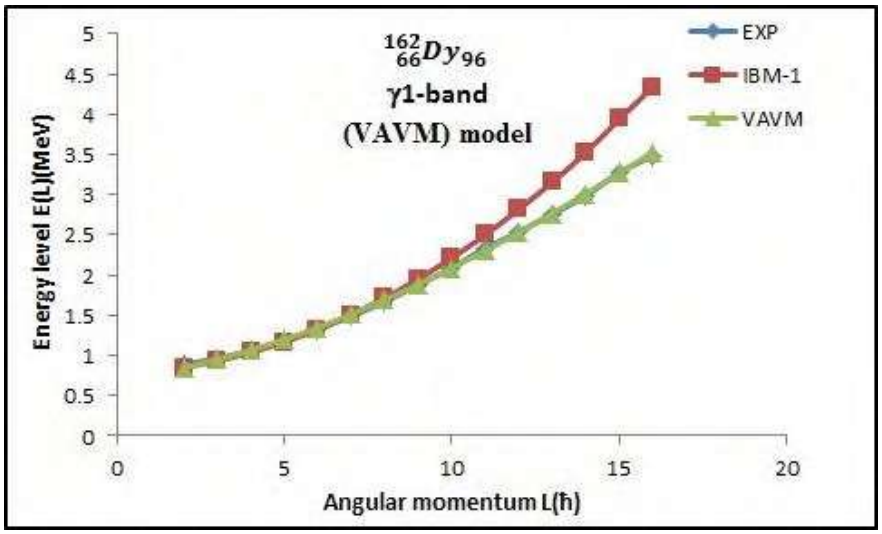

Figure 2. The relationship between energy levels E(L) calculated IBM-1,VAVM and experimental energy levels E(L)versus L for for γ-band

Figure (3) shows the comparison between of the theoretical energy level values E(L) calculated by the two models (IBM-1,VAVM) with the values of practical energy levels as a function of the angular momentum of the β1-band and shows from the shape for (L≤4) there is a match between the values of the practical energy levels with theoretical energy level values calculated according to the two models (IBM-1,VAVM), while for(L>4) is no match between the values of practical energy levels with the values of theoretical energy levels calculated according to the model (IBM-1) while the values of the theoretical energy levels calculated by (VAVM) model is still matching with practical energy level values for (L>4).

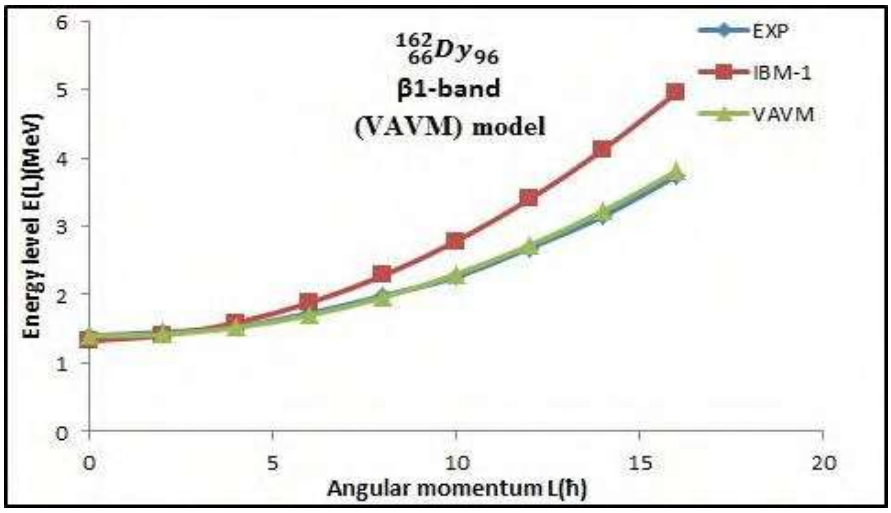

Figure 3. The relationship between energy levels E(L) calculated IBM-1,VAVM and experimental energy levels E(L)versus L for for β1-band

Figure (4) shows that there is a great match between all practical energy level values with all theoretical energy level values calculated by the(VAVM) model of the Beta 2 - band, the values of theoretical energy levels calculated by(IBM-1) model are slightly greater than the values of practical energy levels at low energy levels for (L≤8) while significantly moving away from the values of practical energy levels at excited energy levels for (L>8).

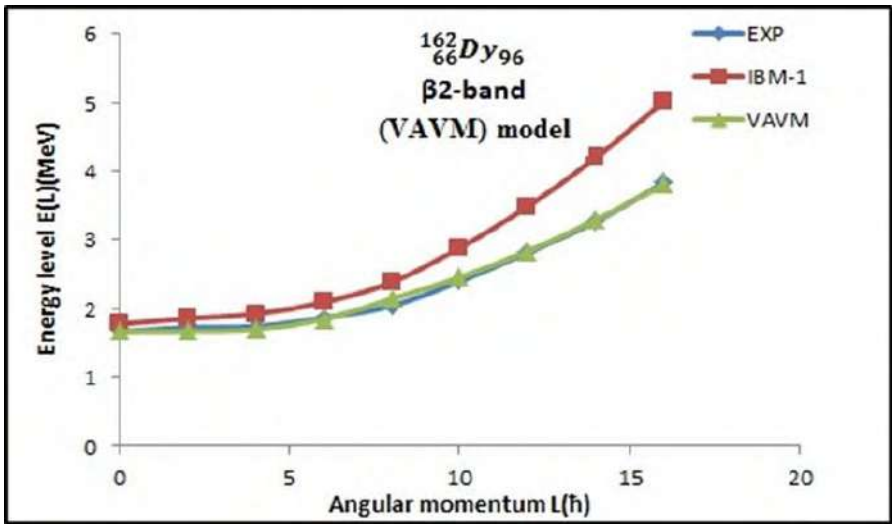

Figure 4. The relationship between energy levels E(L) calculated IBM-1,VAVM and experimental energy levels E(L)versus L for β2-band

Figure (5) illustrates the band intersection phenomenon, which is an important subject because it is use to explain the back bending phenomenon observed from figure (5) that the bands (g1,β1) intersects at the angular momentum $L_{C=}$14,16. And the disintegration of a pair of nucleus generates the energy band intersection and be the back-banding phenomenon that did not appear in the nucleus $^{162}_{66}Dy_{96}$. Due to the decrease in inertial moment at the large angular momentum, the bands intersection also occurs, and the effect of the curious force effect generates a decrease in the energy of the two nucleons, and therefore, the instability in these two states leads to the intersection of one band with another.

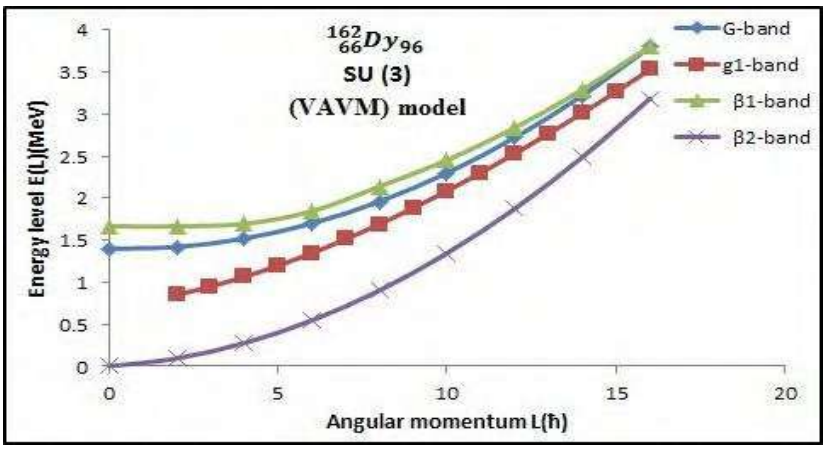

Figure 5. Energy band Intersection E(L)as a function of the angular momentum (L) using (VAVM) model.

The quadrupole moment values (Q_L) were calculated in IBM-1 model using of the(IBMT) program. For via entry file BE2. Dat which requires the determination of the two parameters (β_2,α_2) measured by the unit (eb) shown in table (3).

We note from figure(6)that the shape of the nucleus in the nucleus $^{162}_{66}Dy_{96}$ takes the prolate oval shape at the angular momentum (2_1^+,2_2^+ ,2_3^+ , 2_5^+,2_6^+, 2_7^+,2_{10}^+) while takes the oblate oval shape at the angular momentum (2_4^+,2_8^+ , 2_9^+), and the largest deformation of the prolate oval type is at the angular momentum Q(2_8^+) and its value (-3.729 eb) and the highest deformation of the oblate oval type is at the angular momentum Q(2_3^+) and its value (4.15 eb).

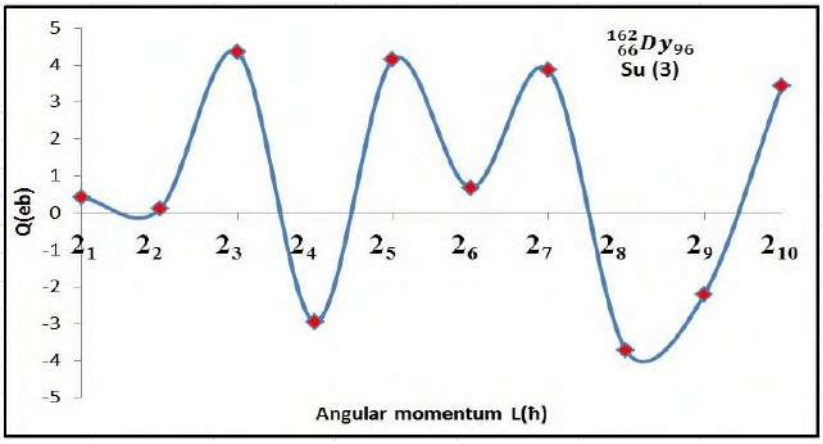

Figure 6. Electric quadrupole moment (Q_L)as a function of the angular momentum (L) from 2_1 *to* 2_{10} .

Abstract. The electron mirror phenomenon has been explored to describe the behavior of a probing electron trajectory inside the chamber of scanning electron microscope (SEM). This investigation has been carried out by means of the modulated mirror plot curve technique. This method is based on expanding sample potential to a multipolar form to detect the actual distribution of the trapped charges. Actually an experimental result is used to guiding results of this work toward the accurate side. Results have shown that the influence of each type of multipolar arrangement (monopole, dipole, quadruple, octopole …etc.) mainly depends on the driving potential.

Keywords: SEM, Mirror effect, Charging process, Insulators samples, Electron beams.

1. Introduction

Now, it is well known that as long as a dielectric material is bombarded by electrons beam, some of these electron straps at surface or even within bulk material [1,2]. Such a situation leads to what so called *Charging Effect* (CE) [3,4] which is becoming very important to comprehend. The use of dielectric material in modern science and technology significantly depends on the realization of CE which in turn could lead to better applications [5,6].

The CE can be investigated in terms of several techniques[7], however, the one that is called *Scanning Electron Mirror Method* (SEMM) is followed in this work. Such an investigation technique provides an excellent ability to control and analyze CE [8]. Anyway, its principle work can be summarized by two steps. The first one imply an implantation of a trapping negative charges beneath the dielectric sample surface using a focused electron beam [9]. In the second step, the scanning mode is used to observe the sample surface with a potential ranging from fractions to a few kilovolts [10]. Actually, increasing the electric field could be strong enough to prevent the next probing electrons from reaching the sample surface. In fact, the surface acts as a convex mirror and reflects the electrons. The mirrored backward electrons will attack the chamber inner surfaces and create new Secondary Electrons (SE), so, their detection will lead to imaging of the insider chamber space rather than the sample.

Obviously, sample potential regulates the characteristics of the appeared electron image, which in turn depend on the way that the trapped charges distribute on the sample surface. So, the knowledge of trapped charges distribution profile is a crucial task to specify physiognomies of mirror images. Recently, the modulated mirror plot curve technique has been presented to detect the actual distribution of the trapped charges[11]. This method is based on expanding sample potential to a multipolar form to identify the spreading of the trapped charges. Current work aims to find the contribution weight of each multipole expansion term which may involve in building up the sample potential.

2. Material and method

The method of charge images has been used recently to solve Poisson's equation inside the chamber of a scanning electron microscope (SEM). Subsequently, the solution in the free space is given by [11];

$$U(\vec{r}) = \frac{K}{4\pi\epsilon_o}\int \frac{\rho(\vec{r})}{|\vec{r}-\vec{r}'|} \qquad \ldots\ldots\ldots\ldots(1)$$

where (ϵ_o) is the free space permittivity, (k) is equal to$[2/(\epsilon_r+1)]$, and (ϵ_r) the relative permittivity. However, equation (1) represents the electrostatic potential at any point located by the position vector $(\vec{r})$ throughout the space (SEM-chamber) that deduced due to an accumulation of a volumetric charges distribution of amount $\rho(\vec{r}')$ located at $(\vec{r}')$. In order to grand equation (1) ability to describe charge extension within the sample, the numerator of this equation is expanded and hence the following expression is obtained;

$$U(\vec{r}) = \frac{KQ_t}{4\pi\epsilon_o r} - \frac{3KQ_t}{32\pi\epsilon_o}\frac{r'}{r^2} + \frac{KQ_t}{64\pi\epsilon_o}\frac{r'^3}{r^4} - \frac{3KQ_t}{512\pi\epsilon_o}\frac{r'^5}{r^6} + \frac{3KQ_t}{1024\pi\epsilon_o}\frac{r'^7}{r^8} + \cdots \qquad \ldots\ldots.(2)$$

where (Q_t) is the trapped charge. The n^{th} term in this equation represents the n^{th} order of multipole moment of the charge distribution of $[\rho(\vec{r}')]$. So, the terms of $(n = 0, 1, 2, 3, 4, 5, \text{ and } 6)$ are respectively the; monopole, dipole, quadrupole, hexapole, octopole, decapole, and dodecapole moment of the trapped charge distribution.

Mirror plot curve is represented the diagram that reveals the relation between reciprocal of Gaussian surface radius and the potential which is used to accelerates incoming electrons (V_{sc}). Consequently, equation (2) has been modified to imply this aspect as in the following formula;

$$\frac{1}{r} = \frac{1}{R} - \frac{3r'}{8R^2} + \frac{r'^3}{16R^4} - \frac{3r'^5}{128R^6} + \frac{3r'^7}{256R^8} - \cdots \qquad \ldots\ldots\ldots\ldots(3)$$

where R is the radius of Gaussian surface for the monopole moment charge distribution which equal to $\left(\frac{\mathrm{KQ_t}}{4\pi\epsilon_o \mathrm{V_{sc}}}\right)$. Indeed, equation (3) shows the mirror plot curve that corrected up to the seventh order, and the even power of (n) are vanishes due to the symmetry of problem. Thereby, it could be adopted to simulate a real (experimental) plot curve and hence verify the distribution profile of trapped charges being taken. Furthermore, contribution of each term should be examined versus the scanning potential in order to define whom the distribution look like to the incoming electrons. Anyway, this is the task of the coming next section.

3. Results and Discussion

Characteristics of a mirror image are mainly depending on the distribution profile for a sample potential that deduced by trapped electrons. Figure 1 shows the potential distribution along the radius of Gaussian sphere surface, for the first four orders of multipole moment terms in equation (2) and the equation itself. These curves are computed at fixed values of the penetration depth and trapped charges namely 10.6 μm and 0.064 nC respectively. Obviously, the monopole term is mainly controlling the contribution in equation (2) along the range of the radius of Gaussian sphere surface. This gives an indication that the higher order of electrons configuration are formed in the regions where a high concentration of electrons being trapped.

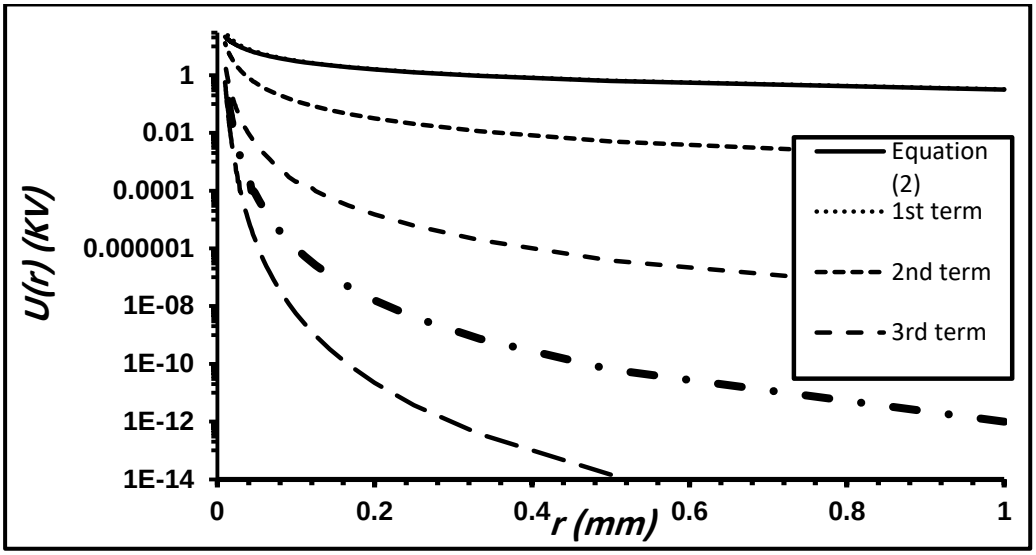

Figure 1. The surface potential distribution deduced by means of equation (2) and each of its term.

In order to provide present calculation a practical interest, some results that presented in the literature[12] have been used to compare with the outcome of equation (3). According to this reference, a Poly(methyl methacrylate) (PMMA) material sample of a dielectric constant 2.6 puts under irradiation by an electron beam with the aid of SEM. This beam has accelerated up to 25 kV, and the sample being under the exposition for enough time to reach the saturation. However, the trapped charges and the probing electron penetration depths are measured to be $(0.064nC)$ and $(10.6\mu m)$ respectively.

Equation (3) and each involved term have been calculated for the values of (ϵ_r, Q_t) and (r') mentioned above. The significance of each term that contributed to builds up this formula as a function of scanning potential are plotted in figure 1. It is seen that the term contributes most to the mirror plot curve $(1/r)$ is the first (zero-order or monopole) one. Indeed, this term fund $(1/r)$ by most of its total worth, and so this supplement, approximately, exceeds the hundred present of its real values for (V_{sc}) greater than$(2kV)$. Such a result indicates that, at $(V_{sc} \lesssim 2kV)$ the incident electron being at a distance approximately greater than $16mm$ away from the sample. Thereby, trapped charges appear to be look like a point for the incident electrons, hence, the point charge approximation works well at these relatively higher distances.

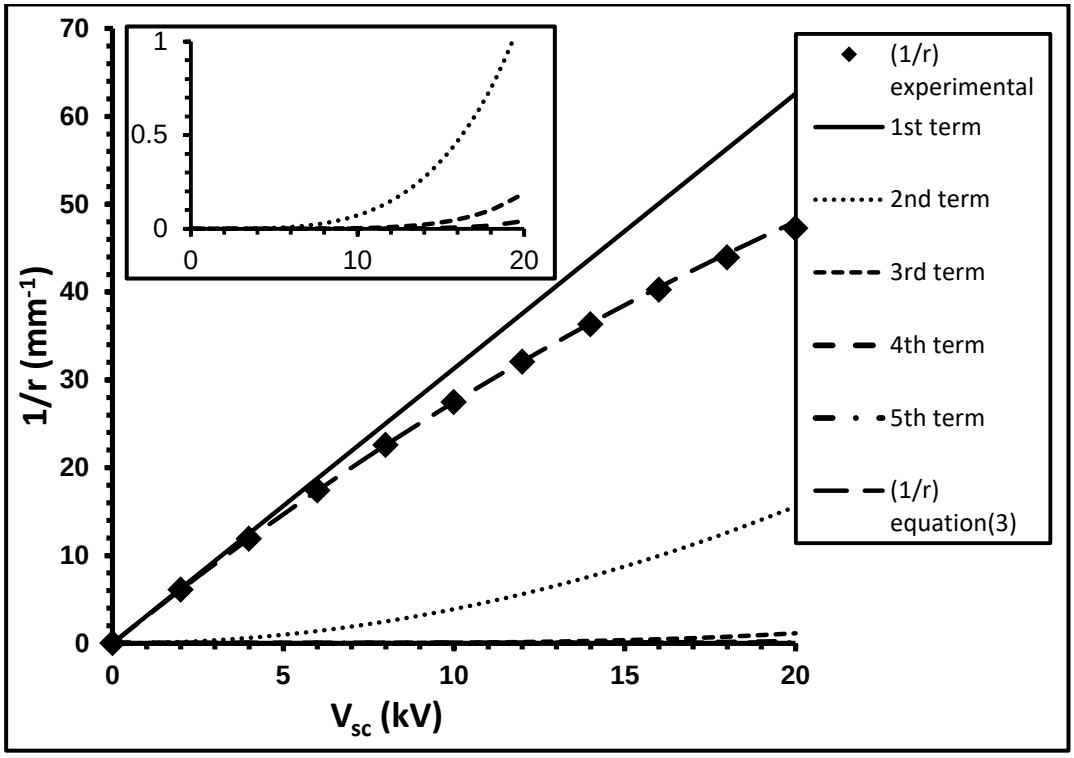

Figure 2. Outcome and the amount of each term in equation (3) versus the scanning potential.

However, when the scanning potential departs from the above mentioned value, i.e. ($V_{sc} \gtrsim 2kV$), the electrons start approache further to the sample. The influence of the second (two-order or quadrupole) term becomes significant and scale down the amount of monopole term. This can directly be seen from figure 1 where the curve $(1/r)$ starts leaving the linearity behavior simultaneously when the quadrupole curve just being noteworthy. Consequently, the point charge approximation fails to work well. Therefore, a trapped charge distribution is no longer appear to be a pure point for incident electrons. Instead, it becomes a mix between point and ellipse profiles.

However, when the acceleration process increases, the contribution weight of the third, fourth and fifth terms respectively become significant. Accordingly, the mirror plot curve becomes under influence of all of these terms by an amount depends on the proceeding of the term itself. Eventually, the point charge model completely failed to represent a point distribution. Hence, incident electron sees trapped charges to be something more complicated and this intricate strength increases as the electron approaches further to the sample surfaces. For accuracy realization, values of equations (3) and its own terms are recorded in Table I.

Table I: Outcomes and the amount of each term in equation (3).

V_{sc} (kV)	1st term (mm^{-1})	2nd term (mm^{-1})	3rd term (mm^{-1})	4th term (mm^{-1})	5th term (mm^{-1})	1/r(eq.3) (mm^{-1})	$1/r_{experimental}$ (mm^{-1})
0	0	0	0	0	0	0	0
4	12.517	0.623	1.83E-03	1.21E-05	1.06E-07	11.896	11.90446
8	25.035	2.491	2.92E-02	7.72E-04	2.72E-05	22.572	22.58321
12	37.552	5.606	1.48E-01	8.79E-03	6.97E-04	32.087	32.03625
16	50.069	9.965	4.68E-01	4.94E-02	6.96E-03	40.530	40.26359
20	62.587	15.570	1.14E+00	1.89E-01	4.15E-02	48.011	47.26521

The variations of the mirror plot curve versus trapped electrons for various values of scanning potential are plotted in figure 3 at a penetration depth of 10.6 μm. It is seen that as long as the higher concentrations of trapped electron are accumulated at the sample surface, the minimum approach distance of scanning electrons being increases. Hence, a landing electron reflected backward at higher distances from the sample surface when higher irradiation potential is used.

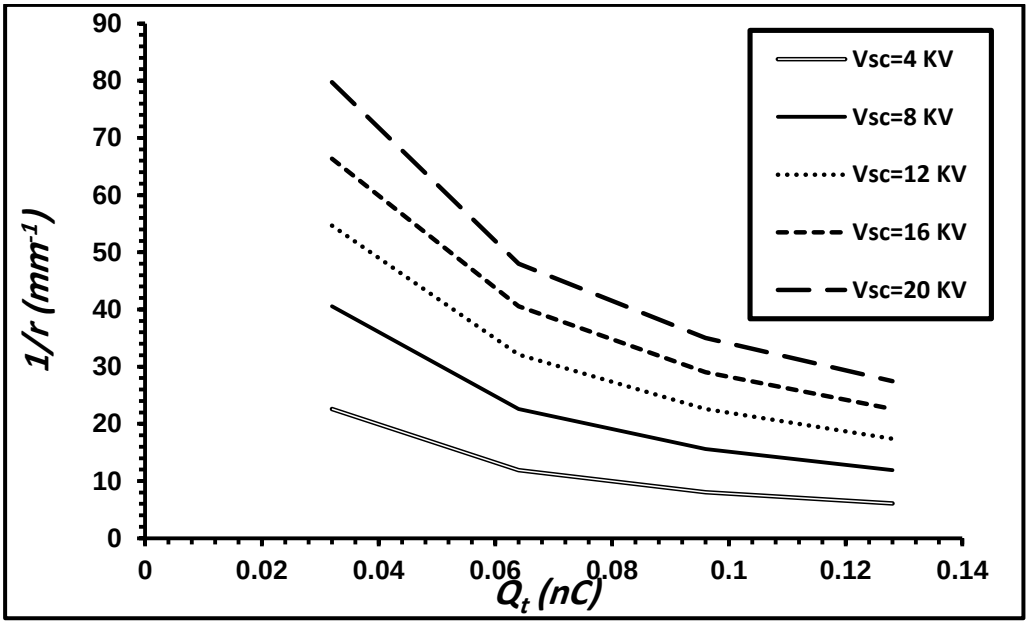

Figure 3. The behavior of mirror plot curve as a function of trapped electron amounts for different values of the scanning potential.

Figure 4 reveals the behavior of the mirror plot curve versus the penetration depth at several scanning potential values, and at the value of trapped electrons equals to 0.064 nC. Indeed, the trapped electrons implanted near the surface of the sample, and these electrons arranged themselves as a point. However, such an arrangement of accumulation takes complicated forms as long as trapped electrons deeply spread inside the sample's body.

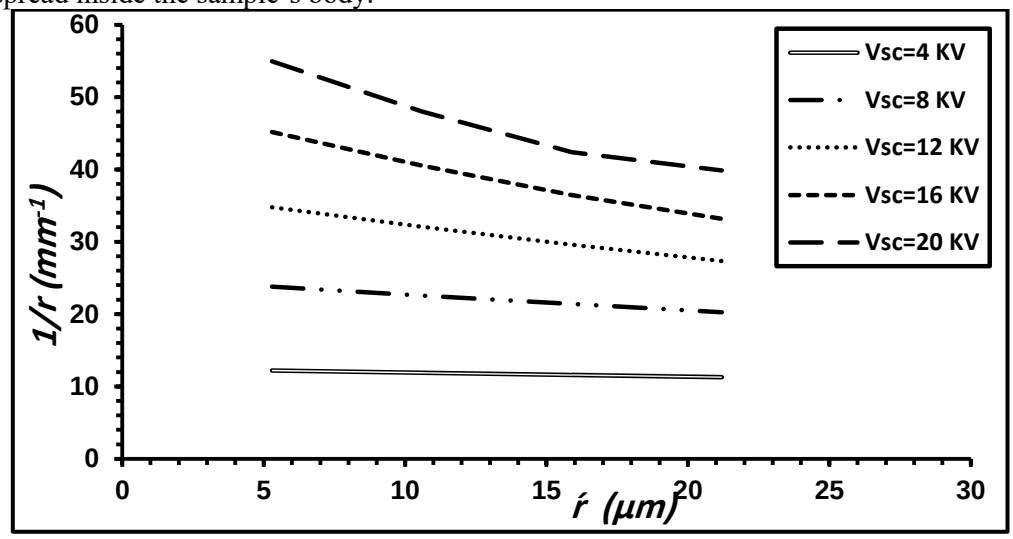

Figure 4. The behavior of mirror plot curve as a function of the penetration depth for different values of the scanning potential.

4. Conclusion

According to the results appeared in the last section, one may realize that the trapped electrons have a complicated formation at the sample's surface. In addition, this sophistication was mutable and not stable along the travel interval of the incident electron. The results of this work have proven that multipolar expansion has an excellent ability to simulate the correspondence experimental mirror plot curves. So, this expansion may regard to be a powerful tool for detecting trapped charges distribution at dielectric materials.

Abstract. In this research, cadmium oxide (CdO) nanoparticle thin films have been prepared at room temperature using a chemical bath deposition (CBD) technique, and the effect of the deposition time were studied. CdO thin films have been deposited on glass substrate from cadmium chloride ($CdCl_2$) as Cd^{+2} ions source and sodium hydroxide NaOH as O^{-2} ions source. The pH value (acidity level) of the chemical bath was fixed at about 11. The CdO thin films structures were analyzed by X-ray diffraction. It shows that all the prepared thin films have a cubic polycrystalline structure with a preferential orientation along (111) plane. All structural parameters were calculated. Particle size for the preferential orientation is calculated between (19.1 -35.5 nm). It is found that the grain size increased with increasing the deposition time. UV-Vis spectrophotometer was used to study the optical properties, and a blue shift in the absorption peaks was noticed. The energy gap values (direct transition and indirect) calculated from the absorption spectrum located between (3.026 -3.409 eV) for direct transitions and (2.197-2.917 eV) for indirect transitions, and this indicates that all CdO thin films prepared nanoparticles. We found that the energy gap decreased with increasing the deposition time.

Keywords; CdO thin film, chemical bath deposition method, Nanostructured, energy band gap.

1. Introduction

Nanoparticles have attracted great interest in recent years due to their size dependent properties and wide range of applications [1, 2].

Transparent conducting oxides (TCOs), such as pure and doped, ZnO, SnO_2, BaO, Fe_2O_3, $BiClO$, Cu_2O and CdO have been studied because of their utilization in optoelectronic device technology. Particularly, CdO based transparent conducting oxide (TCOs) are of great interest due to their metal like good optical transparency in the visible region and charge transport behavior with an exceptionally large carrier mobility [3]. CdO compound is reddish brown in color, and is formed by burning of Cd in air. The oxide is not soluble in water, [4]. CdO is a known n-type semiconductor with the direct band gap energy of 2.2 - 2.8 eV [5], 2.5 eV [6], 2.3 eV [7], 2.25-2.9 eV [8], 2.2-2.5 eV [9],

and the indirect band gap of 1.98 eV [6], 1.36 eV [7], 1.36-1.98 eV [9]. In fact, the differences in the band gap energy are due to the lattice's defects in the crystalline structure [9]. Due to the defect of oxygen vacancies and cadmium interstitials, CdO has special features such as low resistivity (10^{-2} to $10^{-4}\,\Omega\,cm$) [8]. Also, low band gap and high transmission make it applicable solar cells, photovoltaic cell, photodiodes, phototransistors, transparent electrodes, optical communications, smart windows, flat panel display, liquid crystal displays and IR detectors [10, 11, 12]. There are different methods to prepare CdO films such as chemical bath deposition [13], Spray pyrolysis [14], Sol-gel [15] vacuum evaporation [16], successive ionic layer adsorption and reaction (SILAR) method [17]. Among these techniques, CBD method is widely used because it does not require vacuum and sophisticated instrumentation, the starting chemicals are commonly available (simple) and cheap (relatively cost effective) and can be applied in a large area of deposition at low temperature [18,19]. The optical absorption of CdO thin films were accomplished using UV-Vis spectrophotometer Cary50 Cm-Exlenain scan software) in the wavelength range of [190-1100 nm] at room temperature, and the back correction of the glass substrate has been taken in each measurement. The structural characterization of the CdO thin films were accomplished by analyzing the X-ray diffraction patterns obtained using a computer software (MDI/JADE 5) Pgeneral XD-2 X-ray diffractometer (λ= 1.5405 Å for Cu-Kα, current: 20.4 mA, voltage: 36.3 kV), The range of scan in 2θ of (3-75°) with scan speed $4°/min$. The film thickness (t) was found by gravimetric weight difference method.
This work focuses on the Synthesis of CdO nanoparticles thin film on glass substrate using (CBD) technique at room temperature and with different chemical deposition time. The structural and optical characteristics of the prepared films were investigated.

2. Preparations of CdO thin films

Microscopic glass slides of ($75 \times 25 \times 1\ mm^3$) were used as substrates during the deposition process. The substrate was first cleaned with water and soap, after that immersed in chromic acid and boiling for one hour, then cleaned by De-ionized water. Finally it immersed in acetone and rinsed with De-ionized water to remove the surface contaminations and to make the surface more conductive for uniform film deposition.
The deposition process was carried out at room temperature using cadmium chloride monohydrate ($CdCl_2$,H_2O, Merck, 98% purity concentration (0.05 Mol.) as Cd^{+2} ion source and sodium hydroxide ($NaOH$, Scharlau, 99% purity).as O^{-2} ions as shown in Eq. (1)

$$CdCl_2 + 2NaOH \rightarrow Cd(OH)_2 + 2NaCl \quad (1)$$

For the complex formation, an excess ammonium hydroxide (NH_4OH) solution was added (28%) until the clear solution reaches a pH of 11. This clear solution was kept under stirring, and then the substrates were submerged in the solution for (12, 24, 36 and 48 hrs.). Whitish films of $Cd(OH)_2$ were formed on glass substrates. The ($Cd(OH)_2$) films were heated in air at (623 K) for (2 hrs), and the films turn to brown. During the heating process the water vapor rises as shown in Eq. (2)

$$Cd(OH)_2 \xrightarrow{heat} CdO_{solid} + H_2O_{gas} \quad (2)$$

These slides were inclined vertically at 20° angle to the wall of the beaker, and a 3 ml of hydrazine hydrate was added to enhance the adhesion under a constant stirrer (80 rpm).
It is noted that the fresh solution should be continuously stirred to obtain uniform distribution of the chemical components,

3. Theory and calculation

3.1. Structural parameters

3.1.1. Interplanar distance (d)

Bragg's equation was used to calculate the inter-planar distance (d) [20]

$$n\lambda = 2d \sin\theta \quad (3)$$

where (n) is an integer order of the corresponding reflection, (λ) is the incidents wavelength, (θ) is Bragg's angle

3.1.2. Lattice constant (a)

The cubic structure lattice constant (a) is calculated using the relation [20]

$$a = d\,(h^2 + k^2 + l^2)^{1/2} \quad (4)$$

where ($h\ k\ l$) are Miller indices.

3.1.3. Crystallite size (D)

Debye-Scherrer's formula was used to calculate the crystallite size (D) [21]:

$$D = \frac{0.9\,\lambda}{\beta \cos\theta} \quad (5)$$

where (λ) is the wavelength (0.15406 nm) for Cu-Kα source, (β) is (FWHM) full width half maximum of the peak intensity in radians, and (θ) is experimental diffraction angle values.

3.1.4. Average strain (ε)

The strain (ε) is a macroscopic measure of deformation. It is calculated by [21]:

$$\varepsilon = \frac{\beta \cos\theta}{4} \quad (6)$$

3.1.5. Dislocation density (δ)

It is the amount of the defects in a crystal. The simple approach of Williamson and Smallman is used to evaluate it by: [22]

$$\delta = \frac{1}{D^2} \quad (7)$$

where (D) is the average crystallize size.

3.1.6. Texture coefficient (TC)

(TC) of CdO thin films is calculated to quantify the preferential orientation of the films [23]

$$TC(hkl) = \frac{I(hkl)/I_\circ(hkl)}{\sum I(hkl)/I_\circ(hkl)} N \quad (8)$$

where (I) is the measured intensity, ($I_\circ$) is the (JCPDS) standard intensity, and N the reflection number.

TC > 1 implies the preferentially oriented sample.

3.2. Optical study

3.2.1. Absorption coefficient (α)

It is calculated for thin films using Lambert law [20]

$$\alpha = 2.3026\,A/t \quad (9)$$

where (A) is absorbance, (t) is the film thickness.

3.2.2. Energy band gap (E_g)

Energy band gap (E_g) of the films was calculated using Tauc equation [24]:

$$\alpha h\nu = C\left(h\nu - E_g\right)^n \quad (10)$$

where ($h\nu$) is the incident photon energy, (C) is a constant, (E_g) is the band gap and (n) is an index which can take values 1/2, 2, 3/2, and 3 corresponding to allowed direct, allowed indirect, forbidden direct and forbidden indirect transitions respectively.

3.2.3. Particles size of nanoparticles

The particle sizes is calculated by Brus relation [25]

$$E_g^* = E_g + \frac{\pi^2 h^2}{8R^2}\left(\frac{1}{m_e^*} + \frac{1}{m_h^*}\right) - \frac{1.8e^2}{\epsilon R} \qquad (11)$$

where (E_g^*) is the size dependent band gap, (E_g) is the energy band gap of the bulk sample, R is the particle size, (m_e^*) and (m_h^*) are the effective masses of electron and hole respectively (0.21 m_e) for (CdO), (ϵ) is the dielectric constant (6.07) for (CdO) [26].

4. Result and discussion

4.1. Thickness measurement

The film thickness (t) of CdO films was found by gravimetric weight difference method by [27]

$$t = \frac{m}{\rho \, x \, \text{Ã}} \qquad (12)$$

where (m) is the mass of the deposited films in gram (g), (ρ) is the density of the deposited material in (g/cm^3) and Ã is the area of the deposited film in cm^2. Fig.1 shows the variation of the CdO films thickness with deposition time. It is clear that the thickness increases with increasing the deposition time.

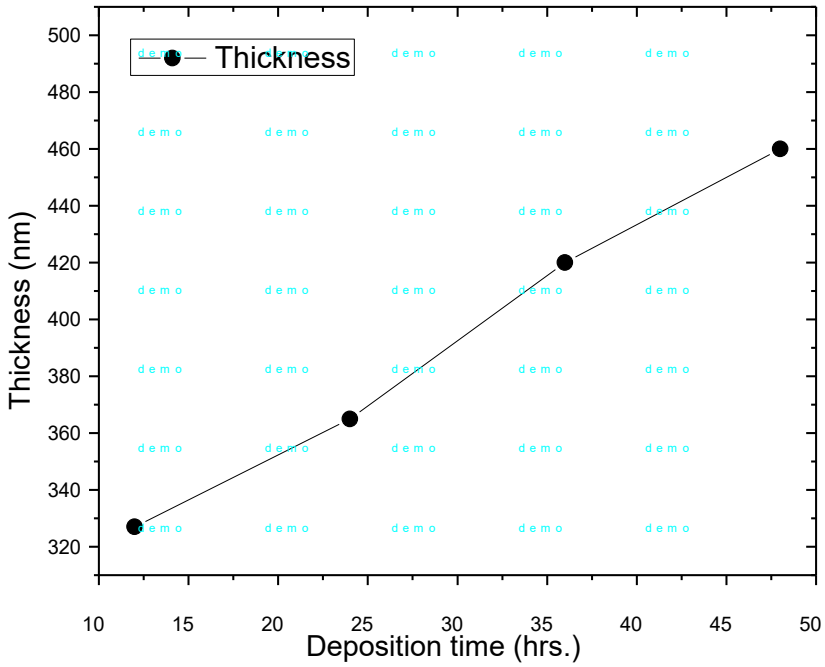

Figure 1. Variation of CdO films thickness with deposition time.

4.2. Structural study

Fig. 2 shows the XRD patterns of CdO thin films deposited at different time (12, 24, 36) h at room temperature and annealed at 623k for (2 h). Fig. 2 shows that the diffraction peaks for CdO films observed at 2θ=(32.91°, 38.313°, 55.2°, 65.858°, 69.211°) are linked to (111), (200) ,(220), (311), and (222) planes respectively. This indicates that CdO films are polycrystalline in nature with a cubic form as compared with the standard data of CdO (JCPDS file no.75-0592) [28] as shown in Table 1. P. Perumal *et al*. observed similar results [29]. XRD shows an increase in the crystallinity with increasing the deposition time. Also, as the deposition time increases, the diffraction peaks are slightly shifted in the direction of higher 2θ values and its intensity increases. The lattice constant (a) of CdO films was estimated by Eq. 4, and the observed (d) spacing was calculated from Bragg's condition Eq. 3. We found a good agreement between the estimated values in this study and the standard data of CdO (JCPDS file no.75-0592) [28] (see Table 1). The FWHM (β) have been evaluated for all diffraction peaks. The FWHM values decreases as the deposition time increases. The Origin software was used in this study for fitting. Texture coefficient (TC) was found to be in the range of (0.591-1.328) by Eq.8, and as the deposition time increases the (TC) slightly increases. The evaluation of the TC indicates the preferred orientation of the films along (111) plane has high crystallinity. Enhancing the preferred orientation is associated with increasing the number of the grains along this plane [30]. The calculated crystallite size (D) was in the range of (19.1- 41.06 nm) by Scherer's formula Eq.5, and as the deposition time increases, the crystallite size increases as shown in Fig. 3. The average strain (ε) was found to be in the range of (0.00148 - 0.00641) by Eq.6, and as the deposition time increases, the average strain (ε) decreases. The oxygen vacancies and the interstitial atoms incorporated in the CdO lattice may be caused the strain [31]. Dislocation density (δ) was found to be in the range of (0.00059 - 0.00274 nm^{-2}) by Eq.7, and as the deposition time increases, the dislocation density decreases.

4.3. Optical study

Fig.4 reveals that the absorbance spectra (A) of the prepared films increases gradually with increasing the deposition time which might be due to increase the grain size with increasing the deposition time that improves the crysallinity and increases the thickness of the films [29]. The optical absorbance of the films decreases with the wavelength. These spectra reveal that CdO films have less absorbance in the visible and high wavelength region and more absorbance in the UV region [32].

The absorption band of CdO nanoparticles shows a blue shift due to the quantum confinement compared with bulk CdO particles. This optical phenomenon indicates that these nanoparticles show quantum size effect [33].

Fig.5 shows the absorption coefficient (α) as a function of the wavelength calculated from Eq.9. It reveals that in the shorter wavelengths, the absorption coefficient (α) exhibits high values which means that there is a large probability of the allowed direct transition. Then (α) decreases with increasing the wavelength. The absorption coefficient (α) values found to be of the order of 10^4 to 10^5 cm^{-1}. Fig.6 shows a direct band gap of CdO films estimated from extrapolation the plot of $(\alpha h\nu)^2$ versus ($h\nu$) Eq.10. The direct band gap energies are (3.026, 3.096, 3.117 and 3.409) eV, and it decreases with increasing the deposition time as seen in Fig .8. These energies are in good agreement with the earlier results reported in [29], and higher than the bulk (2.3 eV). The increase in the band gap of the bulk is due to increasing the free electron concentration in the films. The shift of the band gap with the change in the carrier concentration can be explained by the Burstein-Moss shift [6]. Fig.7 shows the typical Tauc $(\alpha h\nu)^{\frac{1}{2}}$ vs. ($h\nu$) plot for an indirect band gap energy determination. The indirect band gap energy obtained in this case were (2.197, 2.502, 2.539 and 2.917) eV, and it decreases with increasing the deposition time. This energy is higher than the bulk (1.36 eV). Fig.8 shows the variation of the particle size with deposition time. The particle size increases with increasing the deposition time. This confirms the same effect as in XRD study. The particle size of CdO nanoparticles was estimated from Eq.11 in the range of (11.419-12.895) nm for direct energy gap, and (10.374 -12.923) nm for indirect energy gap, Table 3. There is a slightly disagreement between the particle size calculated from the preferred orientation plans using Eq.5 and that calculated from Eq.11.

Fig.8 shows the variation of the particle size with energy gap. The particle size decreases with increasing the energy gap.

5. Conclusions

CdO films have been successfully prepared with high quality, homogenous and gran size in the range of nanoparticles on glass substrates by CBD under different deposition time. The XRD tests of these films revealed that the deposited CdO thin films are polycrystalline in nature with cubic structure having (111) preferred orientation. The influence of the deposition time on the structural and optical properties is studied. By increasing the deposition time (thickness increases), the width of the diffraction peaks decreases resulted in increasing the grain size. We found that the average values of the grain size were in the range of (19.1-35.2 nm) for the preferred orientation indicating that the films are nanoparticles. The optical study revealed that the absorption spectra of CBD (CdO) films increased as the deposition time was increased. A blue shift in the optical gap has been observed for the absorption spectrum of the prepared CdO films, as an indication of quantum confinement effect. The absorption edge slightly shifts towards the higher wavelength with increasing deposition time. As the deposition time increases the energy gap decreases and the particle size increases.

Abstract. Nowadays, the field of radionuclide treatment is enjoying an exciting stage and preparing for further growth and progress in the future. For instance, in Asia, the large spread of liver and thyroid diseases has resulted in several new developments /clinical trials using molecular radiotherapy (i.e. targeted radionuclide therapy). Iodine-124 has unique physical properties including long half-life that adding an advantage for pharmacokinetics and radiopharmaceutical analysis. One of its applications in nuclear medicine is in Positron Emission Tomography (PET).The aim of the present work is to evaluate the production yield of ^{124}I via calculated the excitation functions /stopping power for the reactions^{nat}Te(P,X)^{124}I, ^{121}Sb(A,N)^{124}I,^{nat}Sb(A,X)^{124}I and ^{123}Sb(A,3N)^{124}I in the energy range (3.87-62.95)MeV by using Mat-lab and SRIM programs .

Keyword: Cross section, Excitation function, Iodine-124, Integral yield.

1. Introduction

Generally, Radioisotopes are formed in reactors /cyclotrons to be utilized for diagnostic or treatment purposes in healthcare. The reaction is produced via the energy of the projectile particles to be utilized in the production of the target core and the radioisotopes. For situations where perform an experiment is expensive and hard, simulation studies are preferred to carry out owing to it is save both economy and time [1]. In nuclear medicine, iodine radionuclides are exceedingly utilized for labelling monoclonal antibodies, receptors, and other radiopharmaceuticals, specifically in the applications of diagnostic and therapeutic as quantitative imaging over an interval of a number of days is needful [2]. Unluckily, the nuclides most utilized are ^{131}I, ^{125}I and ^{123}I, and all have restrictions.^{131}I is considered the most commonly used among the three, and it has very high photon energy for optimal imaging. Moreover, rigorous attenuation correction does not allowed via Single-Photon Emission Computed Tomography imaging (SPECT), though a satisfactory empirical correction may sometimes be realized. ^{125}I has a photon energy which is very low for optimal imaging, particularly quantitative imaging, also it has an extremely long half-life (i.e. half-life is undesirably long). ^{123}I has a half-life which is very short. On the other hand, a positron-emitting nuclide is Iodine-124 with a half-life of 4.176 days, and this allows quantitative imaging over several days by Positron Emission Tomography PET (a powerful non-invasive technique for molecular imaging [2–4].

Among its clinical applications are Na, ^{124}I has been used to diagnose/dosimetry in the disease of thyroid and to estimate the springing up of metastatic thyroid carcinoma. Furthermore, [^{124}I]-iododeoxyuridine ([^{124}I]-IUdR) has been used in measuring the activity of proliferation of tumors in

patients suffer from tumors of brain, including gliomas and meningiomas. Besides,[^{124}I]-Miodobenzylguanidine ([^{124}I]-MIBG) has got massive potential for utilizing in cardiovascular imaging, diagnosis, and therapy of malignant diseases like carcinoids, neuroblastoma, pheochromocytoma and paraganglioma [3,5–8]. R. Lambrecht et al in (2010) produced Iodine-124 in great yield through >99.5% radionuclidic purity at (48 h) post irradiation and the ^{124}Te (d,2n)^{124}I reaction. Targetry methodology has been explained. The production yield was (0.55±0.06 mCi/μA.h) [9]. R. Weinreich and E. Knust in (1996) was produced ^{124}I (T = 4.15 d) using a compact cyclotron by the nuclear reaction ^{124}Te (d, 2n)^{124}I via irradiation of$^{124}TeO_2$ with deuterons of energies (14 MeV). And then, dry distillation of the radioactive iodine isotopes generated from irradiated target materials. By-products including (8.02d)^{131}I, (12.4h)^{130}I, (13.0d)^{126}I, (60d)^{125}I and (13.2d)^{123}I have been measured and collected in each charge. After (45 h) decay time, the data demonstration that the total of the activities of these nuclides is below 5% of the ^{124}I activity [10]. S. S. Salodkinand V. M. Golovkov in (2020) have been investigated the methods of production of Iodine-124 radionuclide in nuclear medicine. The effect of target material, the selected nuclear reactions, the irradiation conditions, and the ways of manufacturing / cooling of the irradiated targets on the Iodine-124 yield is considered [11]. In present work, the yield of ^{124}I has been calculated via weighted average cross sections and stopping power of ^{nat}Te(P,X)^{124}I , ^{121}Sb(A,N)^{124}I ,^{nat}Sb(A,X)^{124}I and ^{123}Sb(A,3N)^{124}I reactions by using sets of programs like Mat-lab and SRIM.

2. Decay Scheme of Iodine-124

Iodine-l24 has decay scheme as shown in Fig. (1). At minimum, there are 97 gamma-ray transitions, 25 electron capture transitions and 6 positron transitions. Within the limits, 23% of decays result in emission of positron. Furthermore, there is several high energy gamma rays, some in coincides with the emissions of the positron [2-4].

	Number of distintegrations	Maximum energy (MeV)	Average energy (Mev)

3. Theoretical background

For several decades, the possible use of radionuclides in treatment has been recognized. The most important advantage of radionuclide therapy is the ability to deliver a greatly concentrated absorbed dose to the tumor with preserving the surrounding natural tissue. Targeted radionuclide treatment has become one of the most favourite kinds of cancer treatment due to the administration of radionuclides is slightly invasive and the period of therapy is shorter than chemotherapy. A number of radionuclides including Iodine-124 have been successfully utilized for diagnostic and therapeutic [1,12]. There is a large number of reactions that is utilized for producing ^{124}I, relying on the particles, cyclotron and the

energies that are available in executing the irradiations [5]. In present work, ^{124}I has been produced by utilizing proton induced ^{nat}Te(P,X)^{124}I reaction and α induced ^{121}Sb(A,N)^{124}I ,^{nat}Sb(A,X)^{124}I , ^{123}Sb(A,3N)^{124}I reactions. The energy data for every reaction are obtained from the database of EXFOR and using Matlab programs language to calculate weighted average cross sections (W) for each reaction individually as the following:

$$W=\frac{(\sum wi\ yi)}{(\sum wi)} \quad (1)$$

$$w_i = {}^{1}/_{\mu_i^2} \quad (2)$$

where $\mu_i$is the standard deviation for sample i and yi is the cross section value for sample i [13].The cross section is one of the most significant physical quantity describing nuclear reactions. Experimentally, it can be calculated or measured utilizing varied technique (i.e. models) of nuclear reactions [14].

Furthermore, the integral yield (i.e. the overall number of the formed nuclei through an irradiation time) of these reactions is calculated according to the equation below [15]:

$$Y(t) = t \int_0^L I(x)\,\sigma(x)\left({}^{\rho}/_{ze}\right)dx \quad (3)$$

$$= tI_0 \int_{E_L}^{E_0} \left(-\frac{1}{\rho}\frac{dE}{dX}\right)^{-1}\left(\sigma(E)/_{ze}\right)dE \quad (4)$$

$$= t\,I_0 y \quad (5)$$

Here, ρ is the target isotope number density of sample material, t is the irradiation time, L is the thickness of sample material, $\sigma(x)$ is the cross section to produce the isotope at depth x in the sample, Z is the charge number, I_0 is the number of beam particles irradiating the sample per unit irradiation time, E_0 initial beam energy, E_L is the energy of the beam at the exit of the sample, $\left(-\frac{1}{\rho}\frac{dE}{dX}\right)^{-1}$ is the stopping power and y is the thick target product yield (i.e. is the number of the formed nuclei per unit induced electric charge). It is used for both stable / radioactive products, however is frequently utilized for stable ones.

On the other hand, the number of the formed nuclei existing in the sample material (t) satisfies when the product is radioactive with decay constant(λ)according to the relation below:

$$\frac{dN(t)}{dt} = \frac{dY(t)}{dt} - \lambda\ N(t) = I_0\ y\ -\ \lambda\, N(t) \quad (6)$$

The solution is

$$N(t) = I_0\ y\ \frac{1-e^{-\lambda t}}{\lambda} \quad (7)$$

Then

$$\frac{\lambda N(t)}{I_0} = y\left(1-e^{-\lambda t}\right) = a(t) \quad (8)$$

where $\frac{\lambda N(t)}{I_0}$ represented the activity of the sample material per unit current at t and $a(t)$ is the decay rates of the product per unit current [15].

4. Result and discussion

The values of the cross section for ^{nat}Te(P,X)^{124}I , ^{121}Sb(A,N)^{124}I , ^{nat}Sb(A,X)^{124}I and ^{123}Sb(A,3N)^{124}I reactions are calculated from previous studies [16-29], in the range of energies (3.87-62.95MeV) with a step of (0.5 MeV).

The weighted average cross sections for the above mentioned reactions have been calculated using equations (1 and 2) and rely on the data of proton and α induced, energy and cross sections published via the (EXFOR) library affiliated to the International Atomic Energy Agency by using Mat-lab(8.3a 2014) program .

Moreover, the integral yield ^{nat}Te(P,X)^{124}I , ^{121}Sb(A,N)^{124}I , ^{nat}Sb(A,X)^{124}I and ^{123}Sb(A,3N)^{124}I reactions have been evaluated by using equations (3-8) depended on the values of stopping power that was calculated via Zeigler formula through (SRIM-2013) program. The results of the integral yields are given in table (1).

Table1. Thick target yield of reactions

$Nuclear\ reaction$	$Energy\ (MeV)$	$Thick\ target\ yield\ of\ ^{124}I(\frac{Bq}{\mu A}.h)$
$^{nat}Te(P,X)^{124}I$	$10-20$	$1400-1447$
$^{121}Sb(A,N)^{124}I$	$30-45$	$184.6-200$
$^{nat}Sb(A,X)^{124}I$	$26.72-47$	$446-575$
$^{123}Sb(A,3N)^{124}I$	$32-45$	$1942-2273$

The calculated results of excitation functions andintegral yields are presented in Figures. 2 – 9.

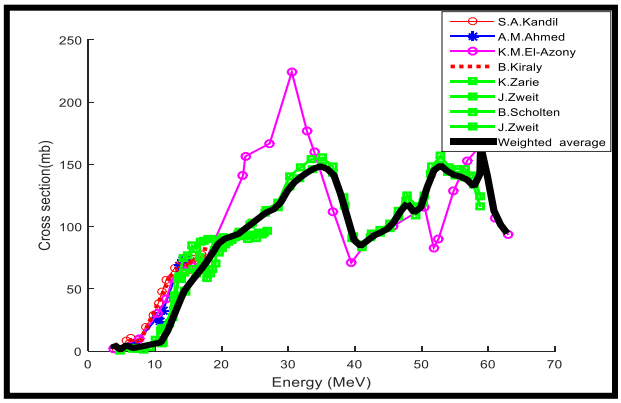

Figure 2. Excitation function of (_^nat)Te(P,X) (_^124)I

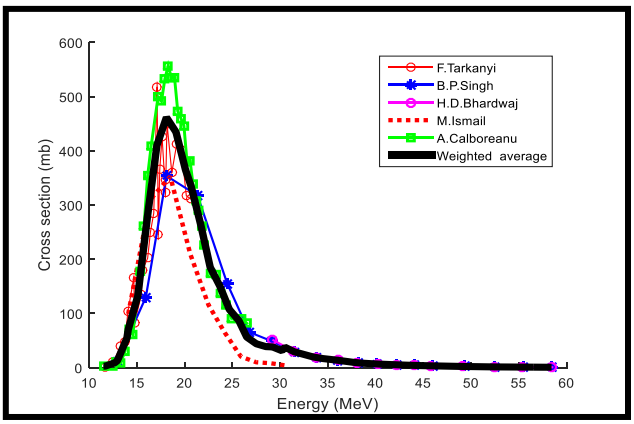

Figure 3. Excitation function of (_^121)Sb(A,N) (_^124)I

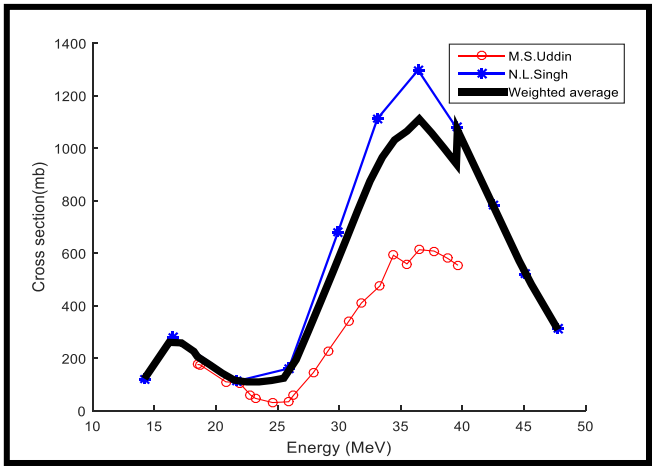

Figure 4. Excitation function of (_^nat)Sb(A,X) (_^124)I

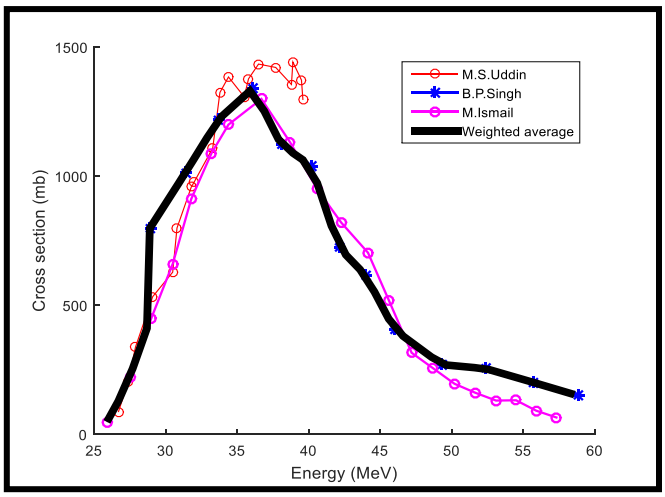

Figure 5. Excitation function of $^{123}Sb(A,3N)^{124}I$

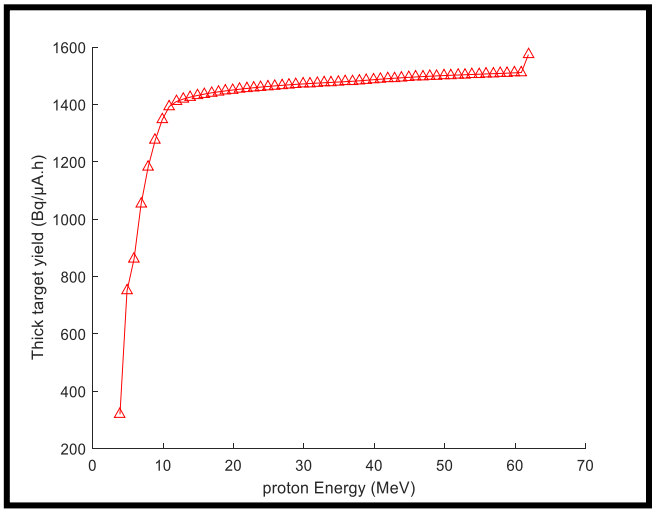

Figure 6. Production Yield for $^{nat}Te(P,X)^{124}I$ reaction

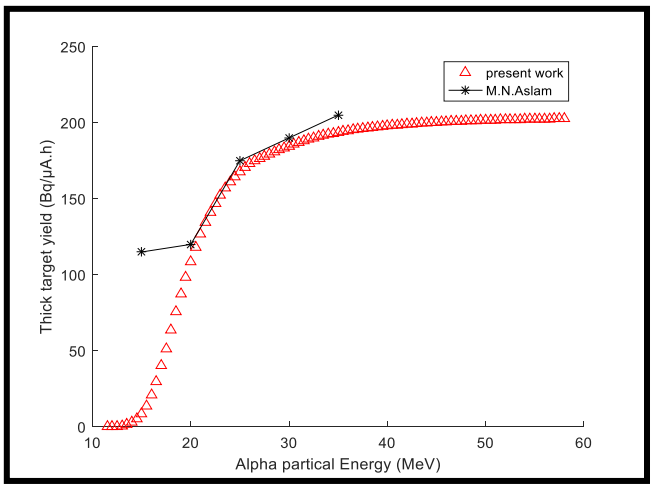

Figure 7. Production Yield for $^{121}Sb(A,N)^{124}I$ reaction.

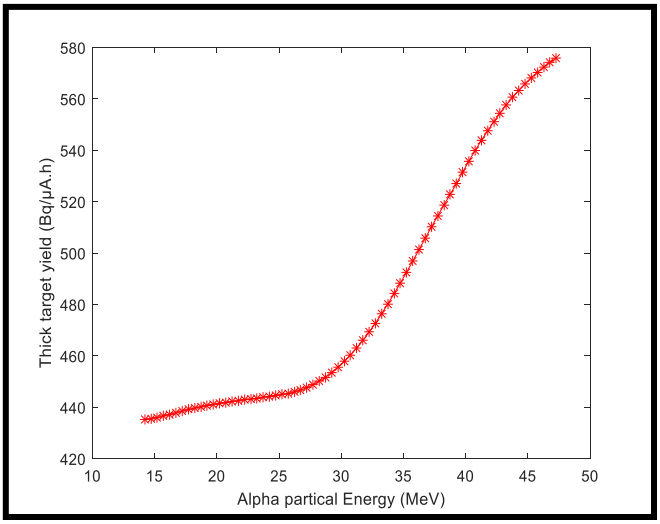

Figure 8. Production Yield for $^{nat}Sb(A,X)^{124}I$*reaction*

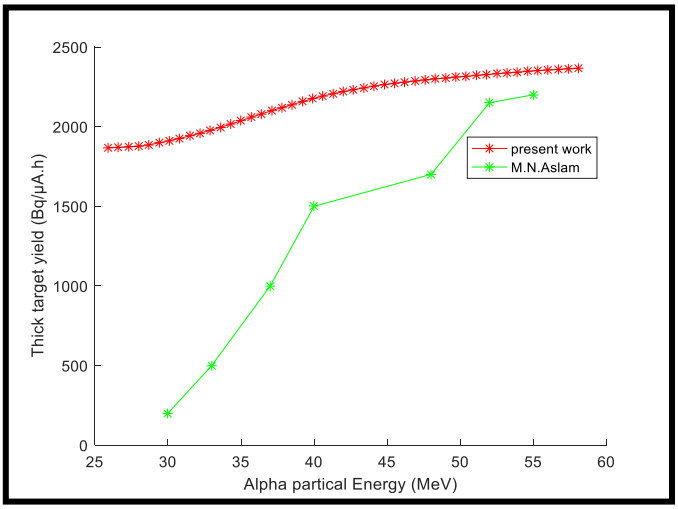

Figure 9. Production Yield for $^{123}Sb(A,3N)^{124}I$reaction.

We observed from figures (2-5) that the cross section of the ^{nat}Te(P,X)^{124}I ,^{121}Sb(A,N)^{124}I ,^{nat}Sb(A,X)^{124}I and ^{123}Sb(A,3N)^{124}I reactions is proportional to the energy of the incident particle.
$^{nat}Te(P,X)^{124}I$ *reaction*: It has two maximum cross-section values which are$(148.3824mb,164.9666mb)$ at energies $(35\ MeV, 59MeV)$ respectively.

$^{121}Sb(A,N)^{124}I$ *reaction*: it has one maximum cross-section value which is$(461.6968mb)$ at about18.1 MeV. After that, the cross-section values start decreasing until reaching to $(0.7882mb)$ at energy $(58.42\ MeV)$.

$^{nat}Sb(A,X)^{124}I$ *reaction* : It has two maximum cross-section values which are $(1.1107 \times 10^3 mb,$ $1.0681 \times 10^3 mb)$ at energies $(36.5\ MeV, 39MeV)$ respectively.

$^{123}Sb(A,3N)^{124}I$ *reaction*: It has one maximum cross-section value which is$(1.33 \times 10^3 mb)$ at energy35.5 MeV. After that, the cross-section values start decreasing until reaching to $(0.1579 \times 10^3 mb)$ at energy of58 MeV.
On the other hand, we noticed that after each maximum cross-section value, the cross-section values begin to decrease as the energy of the incident particle increases.
Furthermore, the integral yield of ^{nat}Te(P,X)^{124}I ,^{121}Sb(A,N)^{124}I ,^{nat}Sb(A,X)^{124}I and ^{123}Sb(A,3N)^{124}I reactions are directly proportional to the energy of the incident particle as shown in figures (6-9).
It is obvious that the values of the yield are different from one reaction to another owing to the difference in reaction cross section and energy of incident projectile. Choosing a suitable energy range for the incident particle improves the production process (i.e. Increases iodine yield and reduces impurities. The yields of reactions ^{121}Sb(A,N)^{124}I and ^{123}Sb(A,3N)^{124}I were in agreement with [30].
Generally, iodine-124 is formed good yield through the nuclear reaction $^{123}Sb(A,3N)^{124}I$.

5. Conclusions

The main objective of this work is the possibility of producing radioactive Iodine-124 to be used in nuclear medicine (i.e. diagnostic and therapeutic applications including Positron Emission Tomography (PET)), as it has physical and chemical properties that qualify it for that.
So, it was produced theoretically from different reactions by utilizing sets of programs like SRIM and Mat-lab. From the results that shown in table (1), we can conclude that the reactions

$^{123}Sb(A,3N)^{124}I$ are the best of other reactions to the production of iodine with the least possible energy (i.e. $^{123}Sb(A,3N)^{124}I$ reaction is ideally suited to produce Iodine-124.

Effect of Gamma irradiation on the structural and optical properties of cadmium telluride thin films

Effect of Gamma irradiation on the structural and optical properties of cadmium telluride thin films

Eman M. Noori

X-ray technical department, Institute of Medical Technology- Baghdad, Middle Technical University, Iraq.

Email: dr.emannoori1975@gmail.com

Abstract. Cadmium Telluride (CdTe) thin films of 2000 Å thickness were deposited by thermal evaporation technique and irradiated with γ-ray energy for the times 24 h, 48 h and 72 h. Structure characterized by x-ray diffraction for both as-deposited and irradiated thin films. The increase in irradiation time appeared an improvement of crystallinity. The transmittance spectra of films using Ultraviolet-Visible spectrophotometer showed the increase in irradiation times leads to decreased in transmittance of films. The energy band gap found direct transition and decrease from (1.6-1.53) eV as the irradiation time increase.

Keywords: Irradiation, structural properties, optical properties, cadmium telluride, thin films.

1. Introduction

Polycrystalline cadmium telluride (CdTe) thin film is a very promising material in recent times due to its use in a large scale in the technology of thin film devices such as photovoltaic detectors [1], solar cells [2], infrared (IR) detectors [3], photo- electrochemical cells [4], etc. CdTe thin films exist in either zinc blende (cubic) or wurtzite (hexagonal) structure[5]. Its direct band gap of 1.45 eV[6], high absorption coefficient $> 10^5$ [7]. CdTe is useful in both heterojunction and homojunction configurations because it can exhibit both p - type and n – type conductivity [8]. Several techniques are available to prepare CdTe films such as electrodeposition[9], chemical bath deposition (CBD)[10], molecular beam epitaxy[11], closed space sublimation[12], Pulsed laser deposition method[13], and thermal evaporation[14]. Thermal evaporation is often prepared due to low trend of oxide formation and modifies the deposition condition.

In the present work, CdTe films deposited on the glass substrate by thermal evaporation. The deposited films were irradiated by gamma radiation, then we evaluated the crystallographic and optical properties and the influence of irradiated times on these properties is also undertaken.

2. Experimental

The thermal evaporation method was used to deposit about 2000Å thin films of CdTe on clean glass substrates at room temperature. The chamber was at a vacuum of the order 2×10^{-5} Toor. The film substrate source distance was fixed at 30 cm. CdTe powder was evaporated using molybdenum crucible. The CdTe films were irradiated by γ- ray Co^{60} and the irradiation time was (24, 48, 72) h. The structure characterization of the thin films studied was performed by a Philips PW 1710 using the CuK_α line

having wavelength of $\lambda = 1.5405$Å. The transmittance spectra of the films (as-deposited and irradiated) were recorded in the wavelength rang (450-900) nm by using UV-Visible spectrophotometer.

3. Results and discussion

Fig. 1 shows XRD patterns for the as-deposited and irradiation films for different irradiation time (24,48 and 72) h. The pattern shows a sharp diffraction peek at 2θ= 23.737 corresponding to reflection (111), which explain as a cubic structure, confirmed by the JCPDS data base no. 15-0770. The irradiation films do not create a new diffraction peek, but we found the crystalline degree increase with irradiation time this is may be due to the atoms have enough electromagnetic energy (γ -ray) to arrange themselves in their crystal lattice [2].

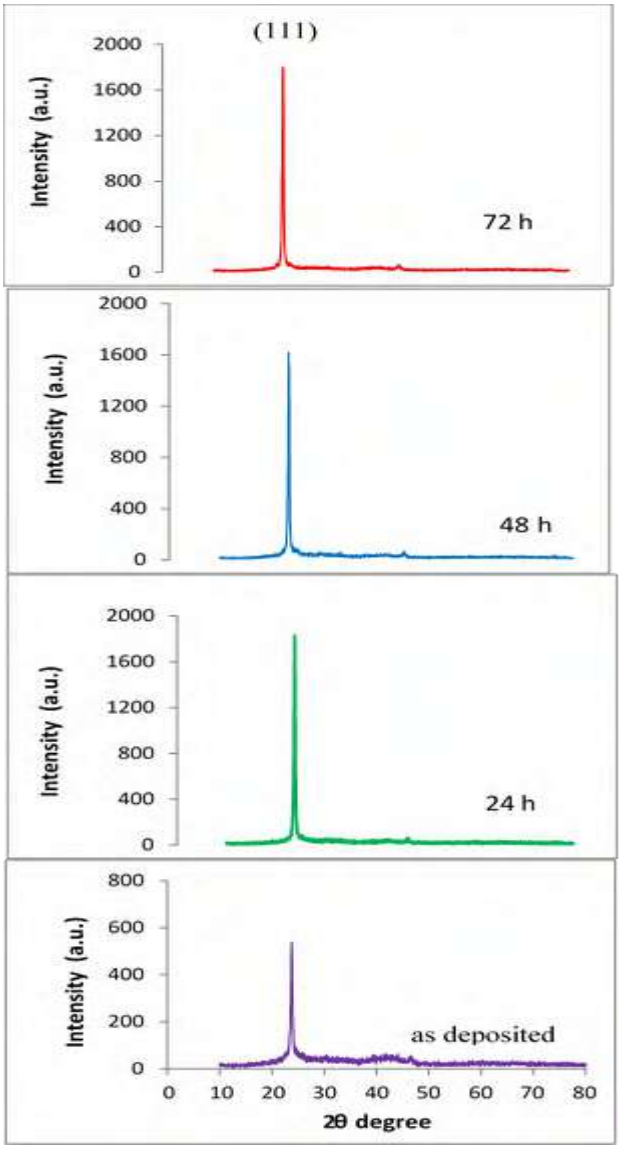

Figure 1. XRD of as-deposited and irradiation CdTe thin films.

The crystalline size D was determined using XRD analysis and given by the Scherrer formula [15].

$$D = 0.94\frac{\lambda}{\beta cos\theta} \quad (1)$$

Where λ is the wavelength of source radiation, β is the angular width at half the maximum intensity (FWHM) and θ is the angle where the peak occurs. As can be shown in Table 1, an increase in irradiation time also influences the crystalline size of CdTe thin films. This indicates that the increase in irradiation time leads to increment of the crystallite size. As irradiated time increases, the atomic, ionic, or molecular of CdTe components obtain a large electromagnetic radiation (γ-ray) leading to a large mobility. Thus, a large number of nuclei are formed which merge to form large crystallites.

Table1. The structural parameters of as- deposited and irradiated CdTe thin films.

irradiation Time (hour)	2θ (deg.)	Plan (hkl)	Grain size D (nm)	Strain (ε)x10^{-3} (line^{-2} m^{-4})	Dislocation density (δ)x10^{15} (line m^{-2})
0	23.793	(111)	21.2515	1.7036	2.2142
24	23.7378	(111)	26.8017	1.3508	1.3921
48	23.7525	(111)	27.1455	1.3337	1.3570
72	23.7383	(111)	27.6581	1.3089	1.3072

Dislocation density δ gives information about the deficiency of a crystal lattice therefore, it was calculated from the equation[16].

$$\delta = 1/D^2 \quad (2)$$

Table 1 revealed that dislocation density decreases as irradiation time increases which indicates better lattice arrangement. The strain ε of thin film regards to disarrangement of the lattice which is created during fabrication of a thin film. The strain was calculated by using the relation[15].

$$\varepsilon = \beta \cos\theta/4 \quad (3)$$

Calculated values for strain shown in Table 1. The strain was found to decrease with increasing irradiation time.

The optical transmission spectrum of CdTe films was recorded in the wavelength range of 450-900 nm. Fig. 2 shows the variation of optical transmittance of the film with wavelength λ for the as-deposited and irradiation time. As-deposited sample shows transmittance higher than the transmittance of irradiated ones and there is a decrement of transmittance with an increment of irradiation time. That is because formation and aggregation of gamma irradiation induced defects – centers, which leads to a reduction of transmittance of irradiation samples[2].

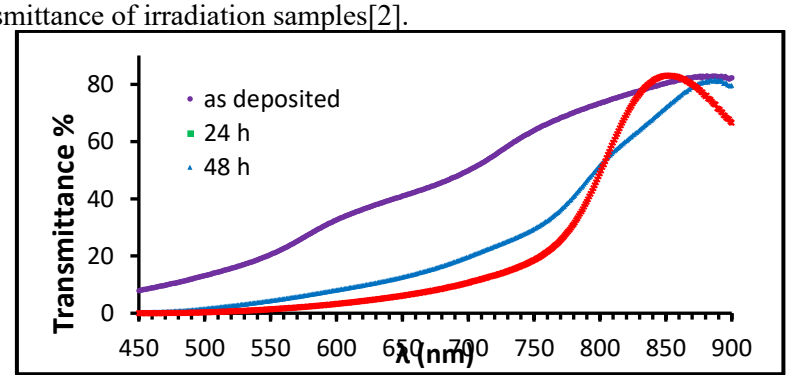

Figure 2. Optical transmittance of as-deposited and irradiated CdTe thin films.

The energy band gap E_g has been calculated by using Tauc relation [16].

$$(\alpha h\upsilon) = A(h\upsilon - E_g)^n \quad (4)$$

Where α is the absorption coefficient, $h\upsilon$ is photon energy, A is constant, n is the integer. Fig 3 shows the graph of $(\alpha h\upsilon)^2$ versus $h\upsilon$. By extrapolating the straight-line portion of the curves to zero absorption coefficients the energy band gap was evaluated and found to be direct.

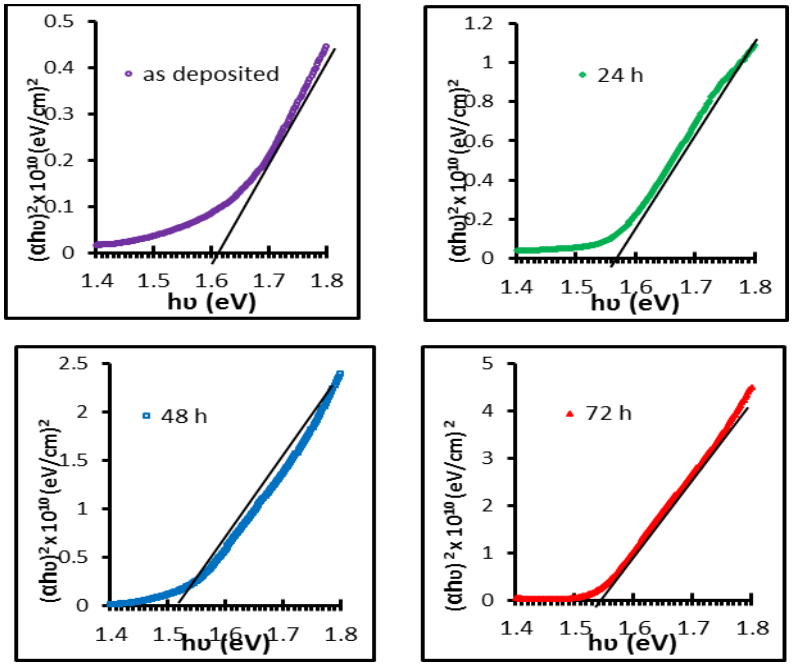

Figure 3. Taus plot of as-deposited and irradiated CdTe thin films.

Table 2 shows that energy band gap decreased as irradiated γ- ray increase. This is attributed to creating several defect levels resulting in more energy. This reduction in energy band gap may also be concluded to increase in crystallite size as shown in Fig. 4 which leads to improvement in the crystallinity as well as decrease in lattice strain as confirmed from structural studies.

Table 2. variation of energy band gap of thin films with irradiated time.

Irradiation time (hour)	Energy gap (eV)
As-deposited	1.6
24	1.56
48	1.54
72	1.53

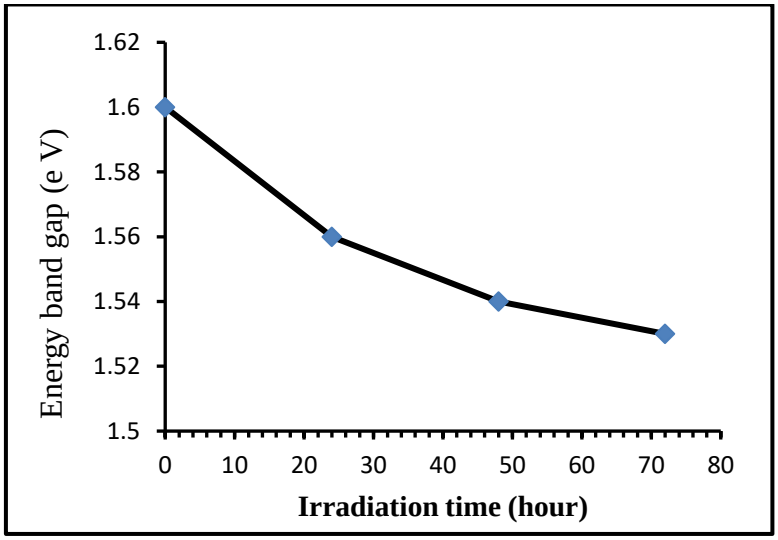

Figure 4. variation of energy band gap with irradiation time.

4. Conclusion

The Thermal evaporation method was successfully used to prepare CdTe thin films. γ- irradiation on CdTe films shows induced physical change in CdTe thin films. XRD analysis appears that films have cubic zinc-blend structure and increase in the crystallite size with increase irradiation time. Transmittance spectra decrease with irradiation increase due to defects-centers. The films have a direct transition and decrease from (1.6-1.53) eV with irradiation.

Abstract. Nanocomposite films of PVA/PAA/$SrTiO_3$ NPs were fabricated for electronic and optic approaches using a low cost method. The AC electrical characteristics of PVA/PAA/$SrTiO_3$ films were investigated. The results showed that the dielectric constant of polymeric blend increases from 5.39 to 7.25, and the dielectric loss increases from 1 to 30. While, the electrical conductivity increases from $5.00E^{-11}$ to $2.00E^{-9}$ with increasing the $SrTiO_3$ NPs content. Also, the dielectric constant of polymeric blend increased from 5.39 to 8.04, and the dielectric loss increased from 0.377 to 1.21. While, the electrical conductivity increased from $2.09E^{-11}$ to $6.70E^{-11}$ with increasing the frequency.

Keywords: PAA, nanocomposites, $SrTiO_3$, dielectric constant, electronic applications.

1. Introduction

Polymers are known to be a conjugating chain of organic materials that show strong electrical conduct ion, which induces charge mobility along the polymers chain due to their characteristics as charges borne by the π-electron. Characteristics of Polymers are as good as with the inorganic matter, but the polymers include many pros, such as good flexibility, corrosion resistance, processability, low cost and light-weight. The inorganic also contains important characteristics like stability to heat, and good mechanical characteristics. Consequently, the polymer/inorganic system have huge applications in several fields [1]. Polymer nanocomposites have expected much interest related to their several industrial fields in water treatment, aerospace food structures industry, drug delivery and aeronautical [2]. The nanocomposites combine useful characteristics of Polymers and other characteristics of nanoparticles [3]. The polyvinyl alcohol/ PVA is a Water/synthetic polymer soluble, non-toxic, and it is generally used in the mixtures owing to its excellent chemical and physics characteristics, good film formation properties, noncarcinogenic, emulsifying capability, biocompatible and biodegradable qualities [4]. The PAA is a hydrophilic Polymer, non-toxic, biocompatible [5]. This work aims to prepare new types of nanocomposites to be used in pressure sensors and piezoelectric fields .

2. Materials and methods

Using the casting process, the nanocomposite films of PVA/PAA blend as a matrix and $SrTiO_3$ NPs as an additive were manufactured. The PVA/PAA film was prepared using a magnetic stirrer by dissolving 1gm of 4:1 ratio polymers in 30 ml of distilled water. The nanocomposite films were prepared by adding the $SrTiO_3$ NPs to different concentrations of PVA/PAA solutions (1.8%, 3.6%, 5.4% and 7.2%). The dielectric properties were Calculated in a frequency range of (100 Hz - 5M Hz) using the LCR meter. The dielectric constant (έ) is determined with the aid of [6]:

$$\acute{\varepsilon} = \frac{C_p}{C_o} \qquad \text{……..(1)}$$

The C_o and C_p are vacuum and capacitance in parallel capacitors .

The dielectric loss (ε″) is determined by [7]:

$$\varepsilon'' = \acute{\varepsilon}\, D \qquad \text{……....(2)}$$

D is a dispersion factor.

The AC conductivity was determined by the following relation [8].

$$\sigma_{A.C} = w\, \varepsilon''\varepsilon_o \qquad \text{……..(3)}$$

W: The angular frequency representation

3. Results and Debate

Figures 1 and 2 represent the dielectric constant and the loss of nanocomposites with PVA/PAA/$SrTiO_3$ and frequency respectively. From these figures, the ε' of PVA/PAA/$SrTiO_3$ nanocomposite reduces with increasing the frequency, which is related to the dipoles tendency in the polymer to orient themselves in the applied field direction. The dielectric loss of PVA/PAA/$SrTiO_3$ decreases with increasing the frequency. This behavior is related to the interfacial polarization in the PVA/PAA/$SrTiO_3$ nanocomposites. The high value at low frequency of ε" for PVA/PAA/$SrTiO_3$ nanocomposite is related to the mobility of the charges [9]. Figures 1 and 2 show the ε' and ε" of a (PVA–PAA) blend, which increase with increasing the $SrTiO_3$ NPs content. This behavior is related to increase the polarizations of the free electrons and the space charges [10,11].

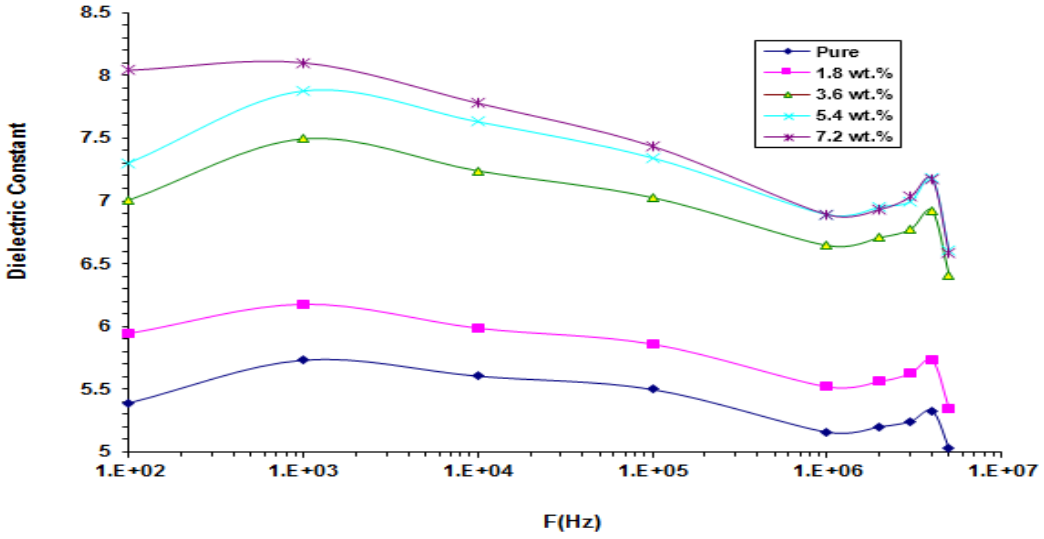

Figure 1. Variation of ε' with frequency of PVA/PAA/$SrTiO_3$ samples.

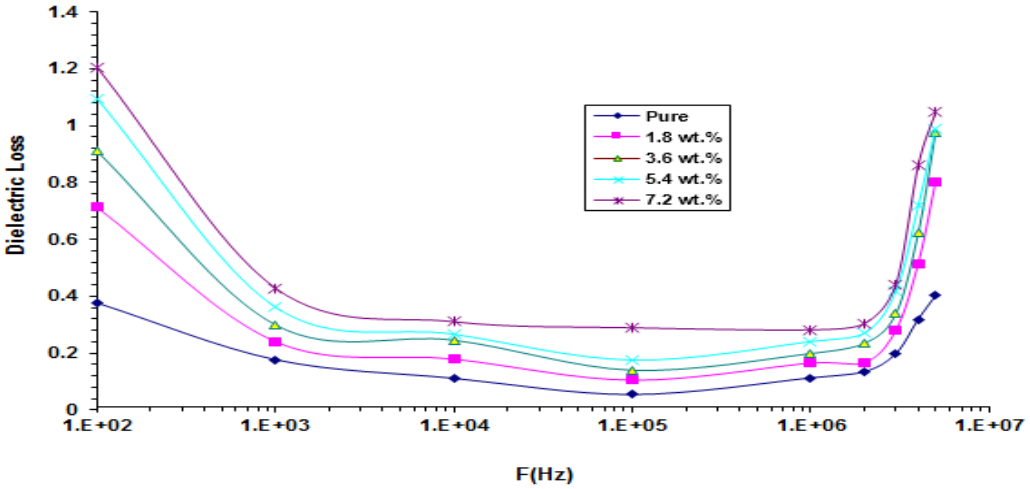

Figure 2. Variation of ε" frequency of PVA/PAA/$SrTiO_3$ samples.

Figure 3 shows the AC electrical conductivity with frequency for PVA/PAA/$SrTiO_3$ nanocomposite. This figure indicates that the conductivity increases with increasing the frequency, which attributed to the influence of the polarization and hopping. The conductivity of PVA/PAA increases with increasing $SrTiO_3$ NPs ratio. This is due to the hopping mechanism of conducting charge carriers [12].

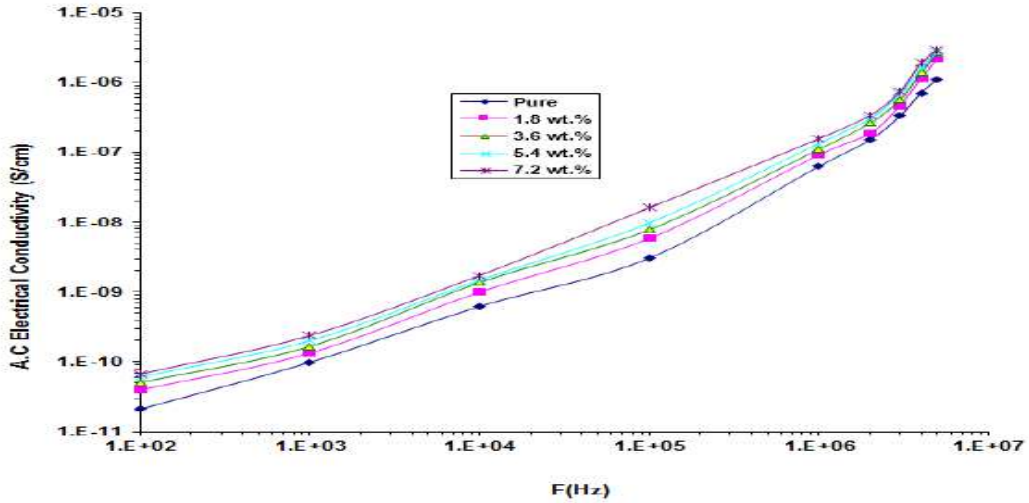

Figure 3. Variation of $\sigma_{A.C}$ with a frequency for PVA/PAA/$SrTiO_3$ samples.

4. Conclusions

The dielectric constant of PVA/PAA increased from 5.39 to 7.25 and the dielectric loss increased from 1 to 30 while the electrical conductivity increased from 5.00 E^{-11} to 2.00 E^{-9} with the addition of $SrTiO_3$ NPs. The PVA/PAA/$SrTiO_3$ dielectric constant increased from 5.39 to 8.04 and the dielectric

loss increased from 0.377 to 1.21 while the AC conductivity increased from $2.09E^{-11}$ to $6.70E^{-11}$ with increasing the frequency. The results indicated that the PVA/PAA/$SrTiO_3$ nanocomposite may be used in various piezoelectric and electronic applications like capacitors, pressure sensors, diode, transistors, .etc.

E-mail:batoolmalkhafaji@gmail.com

Abstract. In this paper, we synthesized new types of nanocomposites to be used in various electronic applications such as piezoelectric, pressure sensors, diodes, transistors with low cost and lightweight. The nanocomposites were obtained from PVA /PEG blend doped with nanoparticles $BaTiO_3$ using casting method then studied using LCR meter. The dielectric characteristics of the synthesized nanocomposites have been studied. Results indicated that dielectric constants ε', loss ε" and conductivity $\sigma_{A.C}$ in PVA/PEG rise as $BaTiO_3$ NPs content increased. Also, the dielectric constant was increased from 5.8 to 8.6 and the dielectric loss was increased from 1.5 to 4.38. The ε' and ε" were decreased while the electrical conductivity was increased from 8.34 to 2.40 at 100 HZ and the $\sigma_{A.C}$ was decreased with increasing frequency.

Keywords: dielectric parameters, $BaTiO_3$, blend, nanocomposites, conductivity.

1. Introduction

Nanotechnology is a topical year, a mainly field special, ranged from new enhancements typical of device physics to precisely novel fields to improving novel have materials nanometer dimensions scale [1]. It is rapidly developing and growing that has large fields in several research approaches, improvement, and industrial activities [2]. Polymer matrix nanocomposites are becoming an essential part of today materials because of several advantages such as low weight, simple fabrication methods, low cost, high fatigue strength, and good corrosion resistance. Nanoparticles incorporation into the polymer matrix considerably alters its physical properties such as the electrical, structural, thermal, and optical properties [3]. The nanocomposites of organic and inorganic are very promising for fields in smart microelectronic, photodiodes, light-emitting diodes, gas sensors, photovoltaic cells etc. [4].PVA/PEG blend has been used in this work due to the it's good dielectric and optical properties this work aims to prepare of PVA-PEG-$BaTiO_3$ new nanostructures films for electronics applications. The $BaTio_3$ has been added to the PVA/PEG blend to get on new nanocomposites Materials have good dielectric properties which make it can be used for different electronic applications.

2. Materials and Methods

The films of PVA/PEG/$BaTiO_3$ nanocomposites using the casting process, they were prepared by. 1gm of PVA/PEG was dissolving in 30 ml using the magnetic stirrer of distilled water with ratio 88%/12%. The $BaTiO_3$ NPs were added to PVA/PEG by ratios are 1.4%, 2.8%, 4.2% and 5.8%. The dielectric characteristics tested in frequency range 100 Hz -5M Hz using LCR meter.

The dielectric constant (έ) is given by the [5]:

$$έ = \frac{C_p}{C_\circ} \quad \text{……..(1)}$$

C_o and C_p are vacuum and parallel capacitances.
The dielectric loss (ε″) is determined by [6]:

$$ε'' = έ D \quad \text{…….....(2)}$$

D is dispersion factor.
The A.C conductivity were calculated by [7]:

$$σ_{A.C} = w ε'' ε_o \quad \text{……..(3)}$$

W: represents the angular frequency

3. Results and Discussion

Figures 1 and 2 show the behavior of ε' and ε" of PVA/PEG/$BaTiO_3$ nanostructures with frequency, respectively. As shown in these figures, the ε' and ε" are reduced with increasing in hesitation owing to a space shipment polarization whose is miniature to the aggregate polarization and becomes the more contributing at low hesitation [8]. The dielectric constant and loss of PVA/PEG blend increased by increasing in $BaTiO_3$ NPs content, this is due to the increasing of the charge carriers [9].

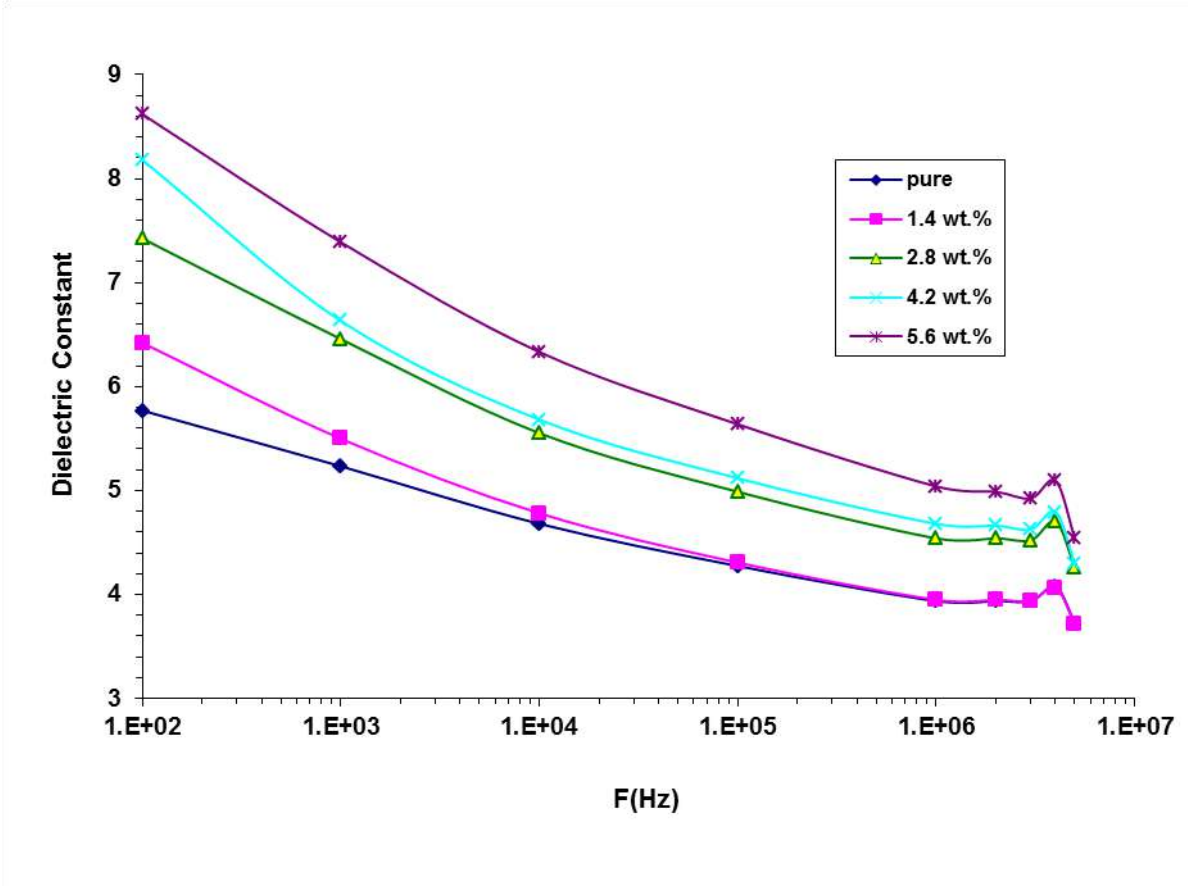

Figure 1. The behavior of ε' of PVA/PEG/$BaTiO_3$ nanostructures with frequency.

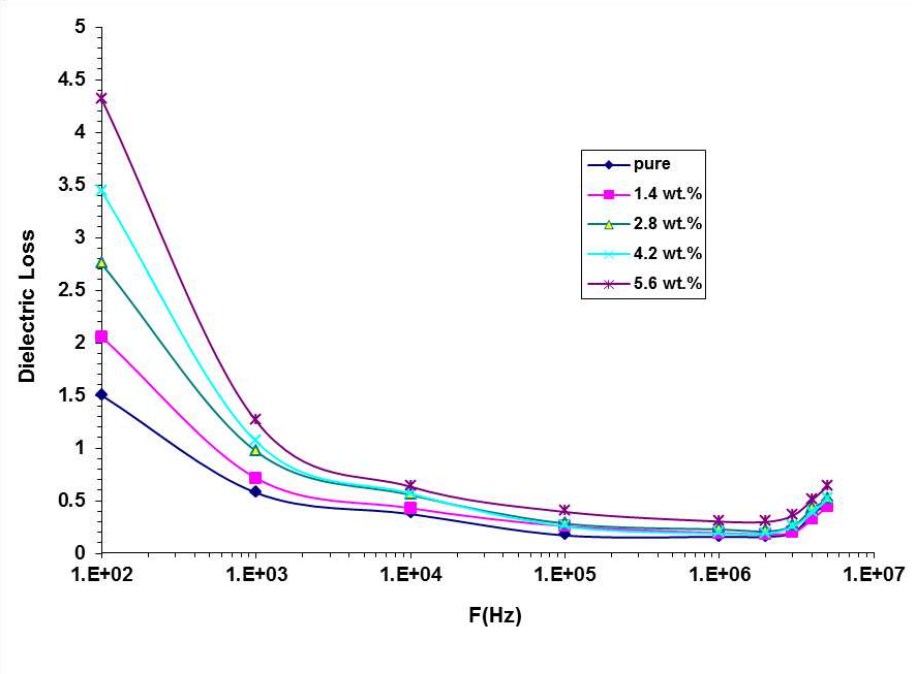

Figures 2. The behavior of ε" of PVA/PEG/$BaTiO_3$ nanostructures with frequency.

Figure 3 shows the behavior of conductivity of PVA/PEG/$BaTiO_3$ nanostructures with frequency. The conductivity rises with rising in frequency, this is related to the mobility of charge carriers and hopping of ions. The conductivity of PVA/PEG rises with rising of the $BaTiO_3$ NPs content. This increase in conductivity relates to rising in charge carriers due to dopant NPs composition which decreases the resistance of nanocomposites and rises the conductivity [10,11].

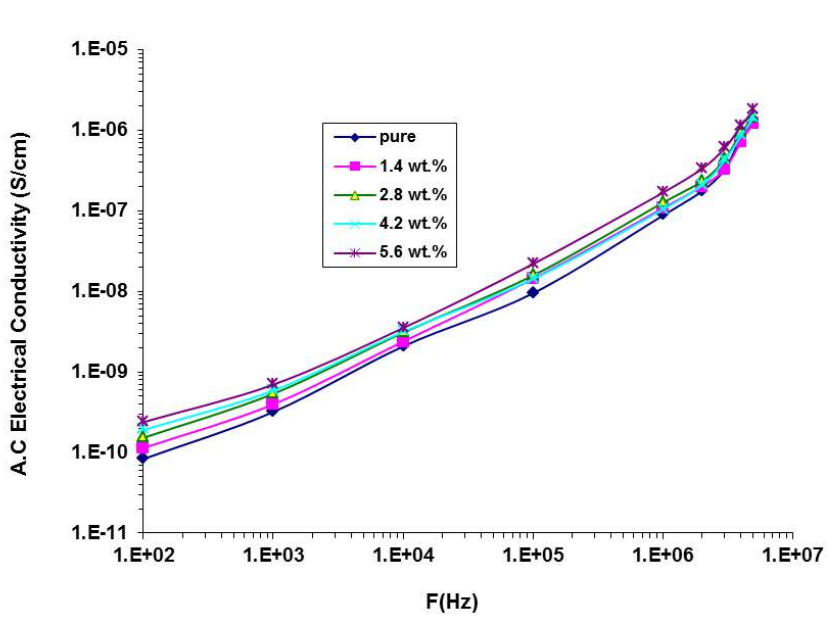

Figure 3. Behavior of $\sigma_{A.C}$ of PVA/PEG/$BaTiO_3$ nanostructures with frequency.

4. Conclusions

In this paper, the dielectric parameters of PVA/PEG were found to be improved with increasing $BaTiO_3$ NPs contents and the dielectric parameters changed with increasing the frequency. Moreover, the dielectric constant was increased from 5.8 to 8.6 and the dielectric loss was increased from 1.5 to 4.38. The ε' and ε" were decreased from 8.34 to 2.40 while the electrical conductivity was increased at 100 HZ. The $\sigma_{A.C}$ was decreased with rising the frequency. The obtained results showed the PVA/PEG/$BaTiO_3$ nanostructures have many applications in electrical and electronic fields.

E-mail: ali.salman@mu.edu.iq

Abstract. A polymer of polyvinyl pyrrolidone (PVP) with fluorescence dye (Flu) was prepared as thin films by casting method with a ratio of (10%) from added the dye. In this case, the optical properties at a wave number range of (200-900) nm were studied. The Absorption (A), transmission (T) spectra, absorption coefficient (α), direct and indirect transitions for energy gap are represented for optical properties. We have found that the polymeric films of PVP/Flu have indirect transition with phonon energy. The indirect energy gap and phonon energy equal to (1.74) eV and (0.15) eV respectively, and the maximum value for (R,K) at the photon energy is (2.3eV). Also, we see that the real (ε_1) and imaginary (ε_2) parts of the dielectric constant increases with increasing the photon energy.

Keywords: *Fluorescence, indirect energy gap, PVP, thin film.*

1. Introduction:

Commercial polymers for materials are complex. They contain more components from other polymers, low molecular weight organic additives, or non-organic fillers. In most experimental studies, preparing polymer blend in a state of mixing and remixing is beginning by a temperature quench because these polymers have high viscosity [1].

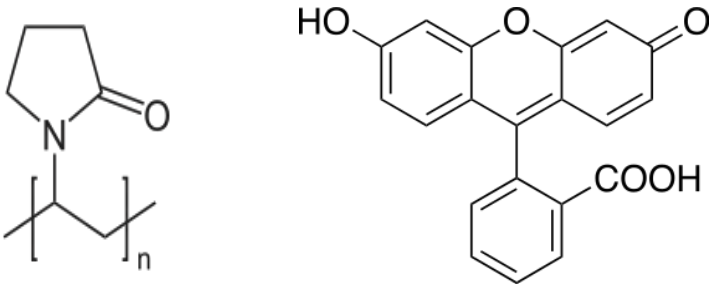
The effect of two bounding interfaces in the thin films is adding an additional complexity to the phase morphologies in ternary blend. In some special cases, simple terms are used to understand the evolving structures. There are three phases for spatial organization for example the phase Y wets the interface of the other two phases X and Z. In this case, the interactions between polymer- polymer at the X-Z interface are much less important compared with the X-Y and Y-Z interfaces, therefore a Y layer intercalates at the X-Z interface to reduce the overall free energy [2].

Polymer materials can be used for electronic applications when it is made highly conductive after electrochemical and chemical treatments. This process is performed by doping with appropriate material. Such as doped Poly (α-Naphthyl Acrylate) with oxoinum salt complex [3], doped Poly butyl benzoxazolylthiophene (PBBOT) with $TBAClO_4$ salt [4]. Also, it can be prepared pyrrole on poly (vinyl-alcohol) using electrochemical polymerization to forming conducting polymer blend (PPy/PVA) [5].

In this work, we examine the effect of Flu dyes on the PVP polymer by preparing polymer thin films using spin coating method, and studies their optical properties.

2. Experimental method:

Polymer polyvinyl pyrrolidone (PVP) and Fluorescence dye (Flu) have a chemical structure described in schematic (1). Thin films are prepared with a ratio of (10%) by casting solution method. The polymer (PVP) and the dyes of (Flu) are easy soluble at room temperature in a distilled water. This solution mixed by magnetic stirrer for 1h, then, the solution was casted on glass substrate (2.5x1.5) cm^2 with a thickness about (24) µm, a thickness can be measured by using (Thickness gauge on steel base). Then, the glass substrate and a solution were with horizontal level to ensure that we get homogenous thin films. Then, we measured the optical properties at room temperature using (TP-180-Uv/Vis. Spectrophotometer) in the wavelength range of (200-900) nm.



a b

Schematic 1. a) Represent structure of polymer PVP.
b) Represent structure of Fluorescence dye.

3. Results and Discussion:

The absorption (A) and transmittance (T) spectra for (PVP/Flu) thin film were recorded by using UV-Vis Spectrophotometer type (TP-180-Uv/Vis.) in the wavelength range of (200-900) nm as seen in Figs.(1&2) respectively, and the relation between them is given by [6]:

$$A = log\left(\frac{1}{T}\right) \ldots\ldots\ldots\ldots\ldots (1)$$

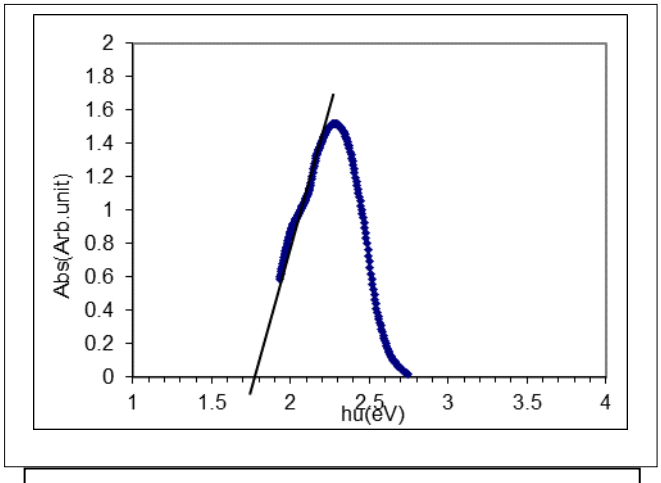


Figure1. Absorption Versus photon energy

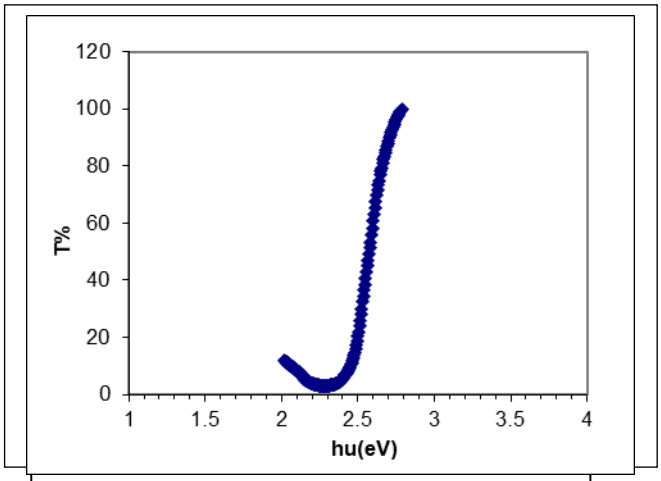

Figure 2. Transmittance Versus photon

From fig.(1) there is one peak appeared in the absorption spectrum at the energy (2.3eV) corresponding to the wavelength (530nm). But, a rapidly increase in the transmittance spectrum beginning from 2.4 eV see fig. (2), the transition in this case was from type $n-\pi^*$ because of the effect of nitrogen bond in the structure [7].
After the correction of the reflectivity, the absorption coefficient (α) of thin films can be estimated by [8]:

$$\alpha = \frac{2.303}{d} A \quad \text{.....(2)}$$

where d is the film thickness.
A is the optical absorbance.
Fig (3) shows the logarithms of the absorption coefficient versus the photon energy, where the values of (α) was calculated from eq. (2) which is less than (10^4 cm^{-1}) [3,9]. This value was very important to determine the type of transition for the electron. When it is less or more than (10^4 cm^{-1}), the type of transition is allowed direct, forbidden direct, allowed indirect and forbidden indirect. From Fig (3) we clearly see that the transition was indirect and obtained the information on the non-vertical allowed transitions which is determined by depending on the theory of bardeenet all [10]:

$$\alpha = \frac{A(h\upsilon - Eg \pm Ep)^2}{h\upsilon} \text{.....(3)}$$

where Eg is the band gap for indirect transition.
Ep is the energy, for phonon absorption the signal is (+) or for phonon emitted the signal is (-)
Figure (4) shows the relation between $(\alpha h\upsilon)^{1/2}$ versus $E = h\upsilon$, with draw two straight lines can be determined each of indirect energy gap and photon energy. The intersection of the energy at lower value represents the limit (Eg-Ep) for phonon absorption transition, and at high value the intersection represents the limit (Eg+Ep) for phonon energy emission. From the intercepts, we found each of Eg and Ep, where Eg is equal to (1.74) eV and Ep of poly (PVP/Flu) is equal to (0.15) eV. These results are very important to improve (PVP) polymer to be used in Photo application.

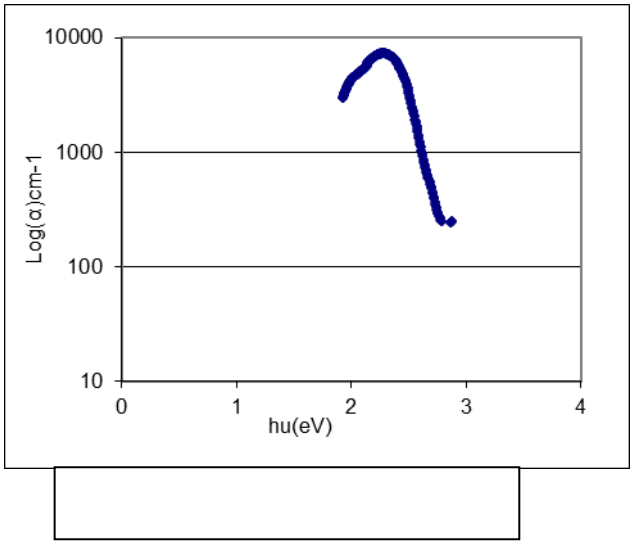

Figure 3

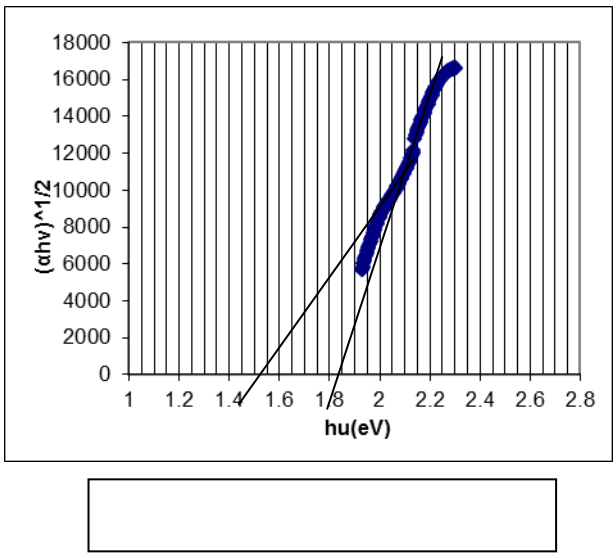

Figure 4

We can also calculate the direct energy gap E_g^A by absorption spectrum which was about (1.72) eV [See Fig (1)], but the direct and indirect energy gaps for pure PVP polymer are (3.88eV) and (3.48eV) respectively [11] as illustrated in Table (1). The value of the energy gap for PVP was decreased because of the effect of fluorescence dyes on the PVP polymer. The relationship below is represented the relation between reflection coefficient (R) and the transmittance (T), so, reflection coefficient can be determined by using it [12]:

$$T = \frac{(1-R)^2 e^{-\alpha d}}{1-R^2 e^{-2\alpha d}} \quad \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

Table (1) shows the values of direct and indirect energy gap for PVP.

Thin films	Direct Eg (eV)	Indirect Eg (eV)	Ref.
PVP(Pure)	3.88	3.48	[11]
PVP/Flu	1.72	1.74	Current work

From the data of (α) values the extinction coefficient (K) can be calculated by:

$$K = \frac{\alpha\lambda}{4\pi} \quad \text{.....(5)}$$

where λ is the wavelength.

Fig (5) shows the relation between (R) versus $E = h\upsilon$, and from this figure we see that the reflection coefficient decreased with increasing the photon energy from (2.3-2.8)eV.

Fig (6) represents the relation between (K) and photon energy. From this figure, we see that the extinction coefficient was decreased with increasing the photon energy at the range (2.3-2.8)eV and the maximum value for was (0.032) at a photon energy of (2.3)eV.

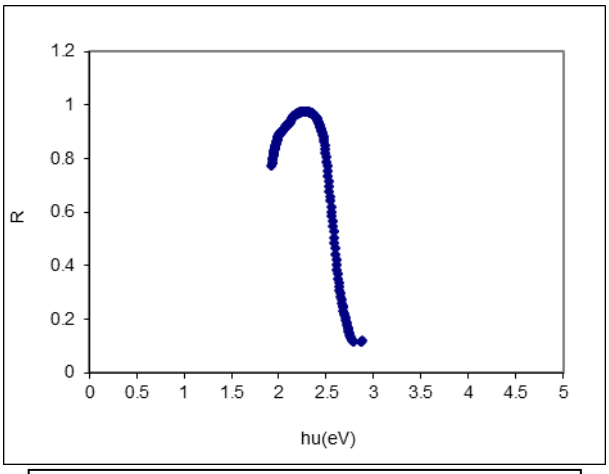

Figure 5. reflection coefficient versus photon energy

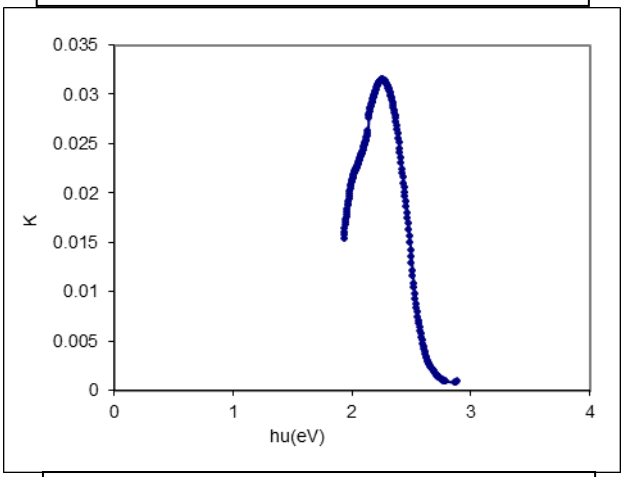

Figure 6. extinction coefficient versus photon energy

For the solid materials, the optical properties are usually described in terms of the complex dielectric (ε) function [13]:

$$\varepsilon = \varepsilon_1 + i\varepsilon_2 \quad \text{.....(6)}$$

where ε_1 is the real part of the dielectric and ε_2 is the imaginary part of the dielectric which can be calculated by:

$$\varepsilon_1 = n^2 - K^2 \quad \text{.....(7)}$$
$$\varepsilon_2 = 2nK \quad \text{.....(8)}$$

where n is the refractive index.

The refractive index is depending on the reflection and absorption coefficient calculated by:

$$R = \frac{(n-1)^2 + K^2}{(n+1)^2 + K^2} \quad \text{.....(9)}$$

Fig(7) Shows the relationship between the real ε_1 and imaginary ε_2 parts of the dielectric constant with the photon energy. From this figure, we see that $\varepsilon_1, \varepsilon_2$ were increased with increasing the $h\upsilon$ and the maximum values of them observed at a photon energy of (2.28) eV.

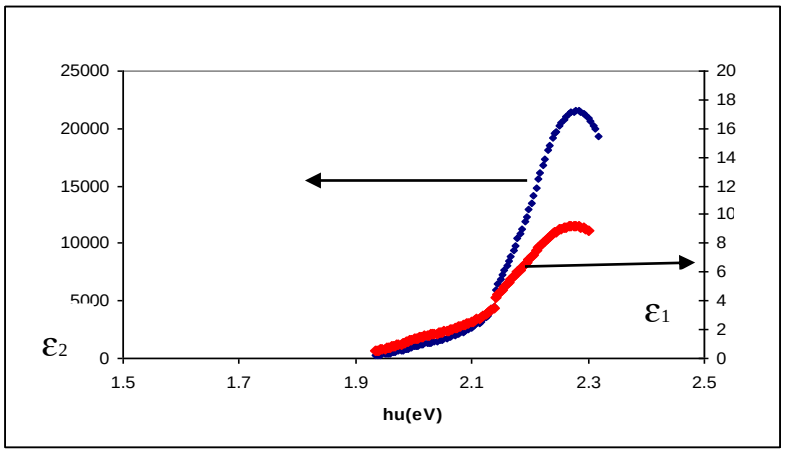

Figure 7. $\varepsilon_1, \varepsilon_2$ versus photon energy

4. Conclusions:

1. PVP/Flu thin films have indirect transition.
2. Thin films of polymer PVP/Flu have lower energy gap equal to (1.74) eV. This value is lead to insert it in photovoltaic applications.
3. The increased in real and imaginary part of dielectric constant was clear with increasing the photon energy, and the maximum value was at a photon energy of (2.28) eV.
4. Thin films have maximum values for (R, K) at a photon energy of (2.3) eV.

Study of Pb Ions Removal from Aqueous Solutions by a Novel Sodium Formate-Coated Magnetite Nanoparticles

Study of Pb Ions Removal from Aqueous Solutions by a Novel Sodium Formate-Coated Magnetite Nanoparticles

[1]Hanan J. Mustafa, [1]Tagreed M. Al-Saadi

[1]Department of Physics/Collage of Education for Pure Science (Ibn Al-Haitham), University of Baghdad, Baghdad, Iraq

E-mail: taghreed.m.m@ihcoedu.uobaghdad.edu.iq

Abstract. One of the problems that continuously happen from the past ages till the present time is the contamination of the water sources with heavy metal ions; as a continuation of the many studies have been done so far to solve this problem. Novel magnetite nanoparticles (NPs) coated with sodium formate (SF-$Ni_{0.31}Mg_{0.15}Ag_{0.04}Fe_{2.5}O_4$) have been prepared using co-precipitation method. Characterization of the prepared SF-magnetite NPs was done by using the spectroscopic devices (XRD), (SEM), (EDX), (FT-IR), and (AAS). From the XRD spectrum it was found that the crystal structure of the prepared SF-magnetite NPs is a cubic inverse spinel structure, which has average crystallite size, the lattice constant, and X-ray density of 28.57 nm, 8.33 Å, 5.29 g/cm^3, respectively. SEM images have shown that the prepared NPs have a sphere-like shape with a measured average crystallite size of 25.93 nm. By EDX spectrum the presence of the constituent elements was confirmed by giving their energy peaks (O: Kα=0.525), (Fe: Kα=6.4, Lα=0.705), (Ni: Kα=7.84, Lα=0.85), (Mg: Kα=1.25), and (Ag: Lα=2.98, Lβ=3.35). The attachment of the SF molecules to the magnetite NPs was proven by the FT-IR spectrum through appearing the absorption peaks in the SF- magnetite NPs spectrum at 1600cm^{-1} and 3400cm^{-1} return to the bonds (C=O) and (C-H stretch) in SF. By ASS results, adsorption of Pb ions was clearly influenced by SF coating giving removal rate (93%) at equilibrium time (10min) in the prepared solution of $Pb(NO_3)_2$ salt, while for the wastewater samples the removal rate was (55%) - (100%).

Keywords: Magnetite NPs, Sodium Formate, Adsorption, Coating, Pb Ions.

1. Introduction

Pollution with heavy metals such as lead, zinc, cadmium and, others is causing serious health and environmental problems. Water contamination with Pb ions is caused by different processes as mining, manufacturing, and smelting, which result in multi-effects that negatively influence human health. The important thing for considering is that metals are resistant to degradation, which end up in living organisms. The existence of the ions of heavy metals represents a big problem because of their toxicity for many lives [1].

Various contaminants removal from wastewater was studied by utilizing different processes [2-4]. The major methods used to purify wastewater from metal ions are adsorption, ion exchange, membrane filtration, flotation, chemical precipitation, and electrolytic [5-8]. Different advantages and

functional operation parameters are presented by different nanomaterials for heavy metal removal due to the high volume surface area, surface chemistry, and a huge amount of particles, surface interactions, and magnetic separation. Their special capability of adsorbing, which are both assistants to the heavy metal ions removal, participates in these characteristics. In the present time, many studies concerned with nanomaterials have been carried out to exam, their capacity to clean wastewater from heavy metal ions and have shown very good potentiality for adsorbing metal ions from polluted water [9-12]. Adsorption is a simple, relatively low-cost and, effective method, utilized to adsorb the metal ions from wastewater. Thus, water treatment by adsorption techniques has become more efficient than by other techniques [13,14].

During the past decades, tremendous studies concentrated on magnetite nanoparticles due to their adsorption strength, high magnetization, special electrical characteristics, and low toxicity to eliminate wastewater contaminants. Magnetic nanoparticles are suitable for heavy metals adsorption from the wastewater. There is a strong magnetic moment in the iron atom due to the existence of unpaired electrons in the orbital (3d) [15]. In magnetic nanoparticles, there is a great ability for aggregation. So, surface modulation functional groups is necessary to improve the magnetite nanoparticle's stability [13, 14], to enhance their physicochemical features, and to accomplish different kinds of applications [16].

Fawzia et al. [17] have prepared magnetite NPs of (Fe_3O_4) by co-precipitation method, stabilized by non-ionic and cationic surfactants. The cubic crystalline structure of the prepared magnetite was confirmed by XRD. Uniform dispersity was ensured by TEM images. The adsorption efficiency of the prepared NPs for Pb, Zn, and Cd was examined by ASS by changing several factors as pH of the metal ion solution and the doses of the adsorbent. The adsorption equilibrium was achieved within (4) hr., and was highly affected by the pH of the solution and the dose of the adsorbent. Khai et al. [18] have used sludge as an adsorbent from an iron-ore area to remove Mn, Cd, Zn, Pb, and as from aqueous solutions. The capacity of adsorption of the adsorbent was examined in a set of experiments including the use of single and mixed metal solutions. It was found that the adsorption capacity of the heavy metals is ordered as Pb>As >Cd >Zn >Mn. Moreover, in the single-metal, solution is ranged (0.7-1.113) mg/g; while in the mixed-metal solution is, ranged (0.370-1.059) mg/g. iron-ore sludge has been proved that it is an efficient adsorbent for plenty of metal ions and its promising adsorbent for toxic metal pollutants from water. Jin et al. [19] studied (Fe_3O_4) magnetite NPs adsorption properties for Cr(VI) and Cu(II) that are coexisted in the mixed solution. They investigated different factors, adsorbent dose; metal ions initial concentration, pH, and temperature. The results revealed that pH influenced the adsorption of the two metal ions and the optimal pH was 4.0. The increment of adsorbent dose increased the adsorption efficiency. It was found that temperature had no clear effect under the practical design. The maximum adsorption capacity of 2.0g/dm^3 of Fe_3O_4 was found to be 18.61mg/g and 8.67mg for Cu(II) and Cr(VI) respectively in 80mg/dm^3 mixed solution for both metal ions. Fe_3O_4 nanoparticles performed as a good adsorber and are separated easily and recovered once a magnetic field is applied to it.

Sodium formate (SF), HCOONa, is the sodium salt of formic acid, HCOOH. It's an environmentally friendly salt and it has multiple uses as in fabric dyeing and printing processes. It is also used as a buffering agent for strong mineral acids to increase their pH, as a food additive (E237), and as a de-icing agent [20, 21].

SF has never been used in the field of heavy metal ions removal from aqueous solutions but could have a positive effect on the adsorption process due to its chemical nature; so this study was aimed toward discovering the effect of sodium formate on the adsorption capacity of the prepared magnetite NPs for Pb ions removal from different aqueous solution.

2. Materials and Methods

2.1 Materials

$Ni_{0.31}Mg_{0.15}Ag_{0.04}Fe_{2.5}O_4$ Magnetite NPs were prepared by using metal sulfates, these sulfates included ferrous sulfate ($FeSO_4.7H_2O$, 99.0%), nickel sulfate -6-hydrate pure ($NiSO_4.6H_2O$, 99.0%), magnesium sulfate heptahydrate AR ($MgSO_4.7H_2O$, 99.5%), silver sulfate (Ag_2SO_4, 99.0%), potassium nitrate (KNO_3, 99.9%), potassium hydroxide (KOH, 99.5%), and sodium formate (HCOONa, 98.0%).

2.2 Preparation

$Ni_{0.31}Mg_{0.15}Ag_{0.04}Fe_{2.5}O_4$ magnetite NPs were prepared by the co-precipitation method as used by Jawaher et al. [22]. 0.12M of the following sulfates ($FeSO_4.7H_2O$), ($MgSO_4.7H_2O$), ($NiSO_4.6H_2O$), and (Ag_2SO_4) were dissolved in deionized water (50ml). KNO_3 (1.01g) was dissolved in deionized water (10ml) and was added to the former solution, then stirring the solution for 30min. After that, a solution of KOH (1.402g was dissolved in 10 ml of deionized water) was slowly added to the last solution. The final mixture was heated until the mixture temperature reached 100°C then the reaction mixture remained at this temperature for 2h; the precipitate was cooled down to room temperature and then washed with deionized water several times and dried at 50°C overnight. Finally, the prepared magnetite NPs were sintered at 600°C for 2h.

2.3 Coating

The coating procedure was done as mentioned in ref. [22], but the ratio of magnetite NPs to the coating material was 1:6 due to the experiment. 6g of sodium formate (SA) were dissolved in 200ml of deionized water, and then 1g of magnetite NPs was added to the sodium formate solution. The last solution was mixed for 1h. The mixing process, magnetite NPs were washed with deionized water several times and left to be dry at room temperature.

3. Characterization

The crystallographic structure of synthesized magnetite NPs was examined by XRD (x-ray powder diffraction) by the instrument (XRD-6000 Shimadzu) with a Cu target, λ=1.54 Å, and angle 2θ=20-80 degree. The surface characteristics of the NPs were observed utilizing a scanning electron microscope (SEM TESCAN MIRA3) equipped with energy-dispersive X-ray spectroscopy (EDX). Magnetite NPs were also characterized by Fourier transform infrared (FTIR) spectrophotometer (IRPrestige-21 Shimadzu). Pb ions concentrations were measured by the atomic absorption spectrophotometer (AA-7000 Shimadzu).

4. Adsorption Process

Two aqueous solutions have been used in this process, the first one is a prepared solution of Pb $(NO_3)_2$ prepared to have (25ppm) of Pb ions in a bottom flask of 50ml for each sample. The second solution represents two samples of the wastewater of a battery factory located at Al-Waziria, Baghdad, Iraq; the first one is contaminated with Pb ions, sample (C), and the second one is filtered by the factory staff, sample (P). The adsorption process was done at 30°C in a water bath shaker at (100 rpm). The dosage of magnetite NPs understudy was (0.1g) for different contact times (5, 10, 15, 20, & 25) min. Magnetite NPs were removed from the solution by a magnet after the adsorption process was done. This solution was tested by atomic absorption spectrometer (AA-7000, Shimadzu) for detecting Pb ions concentrations remained after the completion of the adsorption process. The adsorption amount (qt) and the removal rate (A%) were calculated using the relation (1) and (2), respectively [18, 23].

$$q_{t=(C_0-C_t)\times\frac{V}{m}} \quad (1)$$

$$A(\%) = \frac{C_0-C_t}{C_0}\times 100 \quad (2)$$

Where C_0 is Initial Pb ion concentration in (mg/L) at time t=0, C_t denotes Pb ion concentration in (mg/g) at time =t, V represents Volume of water in (ml), and m= Weight of the magnetite NPs in (g).

5. Results and Discussion

XRD pattern of the synthesized magnetite NPs is illustrated in Fig. 1. The structural properties were studied in the range of (20°-80°). This diffraction pattern clearly coincides with the standard pattern of the cubic spinel magnetite phase JCPDS no. (19-0629) [24]. The remarkable peaks of the synthesized magnetite NPs were indexed to the crystal planes of the cubic inverse spinel iron oxide (Fe_3O_4), which

are found to be (220), (311), (400), (422), (511), and (440); corresponding to the diffraction angles 30.22°, 35.68°, 43.38°, 54.10°, 57.16°, and 62.56° respectively. Also, there is an appearance of extra peaks than (Fe_3O_4) peaks return to other phases of iron oxide (cubic γ-Fe_2O_3 and tetragonal γ-Fe_2O_3 (incomplete)); these phases appear as a result of the sintering process, where cubic γ-Fe_2O_3 appears at 200°C, while tetragonal γ-Fe_2O_3 appears at 600°C [25]. The average crystallite size of the synthesized magnetite NPs was calculated using Scherrer 's formula [26, 27], its value was found to be 28.57 nm.

$$D = \frac{0.9\,\lambda}{\beta\,\cos\theta} \quad (3)$$

Where λ is the wavelength of the X-ray and β denotes FWHM in radians.

It is worth saying that only magnetite particles having a particle size less than 30 nm exhibit super paramagnetic properties and have a large surface area that make them prone to magnetic fields and without an external magnetic field to support them; they do not become permanently magnetized. These properties are highly useful in the novel separation process development [28].

The lattice constant was calculated using Rietveld refinement and it was found to be 8.33Å. In addition, the x-ray density was calculated using the formula (4) and has a value of 5.29 g/cm^3 [29].

$$\rho = \frac{8M_w}{N_A.a^3} \quad (4)$$

Where (M_w) is the molecule weight, (N_A) is Avogadro's number, and (a) is lattice constant.

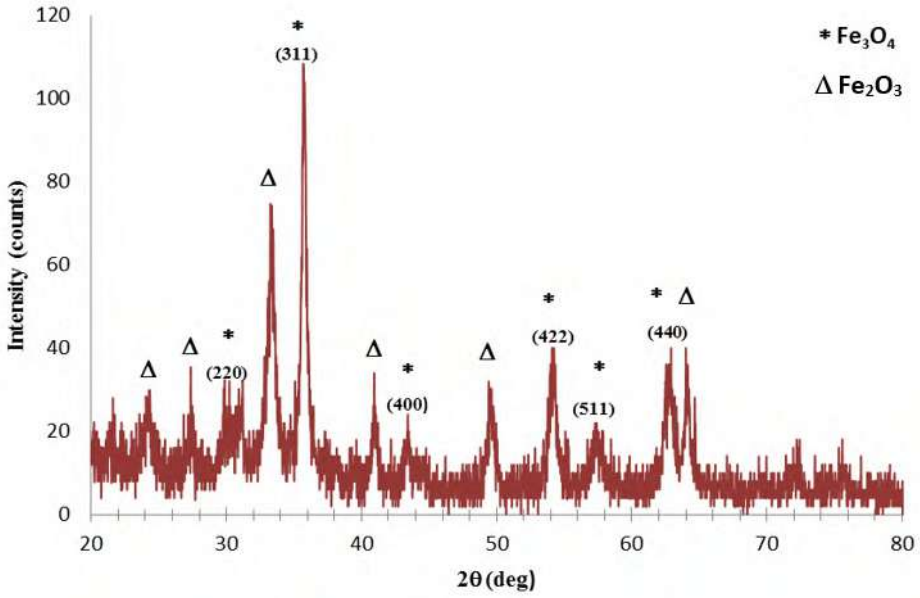

Figure1. XRD pattern of the ($Ni_{0.31}Mg_{0.15}Ag_{0.04}Fe_{2.5}O_4$) magnetite NPs.

Scanning Electron microscope (SEM) image of the synthesized ($Ni_{0.31}Mg_{0.15}Ag_{0.04}Fe_{2.5}O_4$) magnetite NPs at magnification of 200 nm is shown in Figure 2a. It can be noticed from this figure the homogeneity and uniformity of the synthesized NPs, they have sphere-like shape and are distributed regularly. Figure 2a also proves that the synthesized NPs are in the nanometer range have an average crystallite size of 25.93nm which is so close to that has been calculated by Debye Scherrer 's formula. The high porosity of the synthesized NPs is remarkable and that increases the capacity of ion adsorption on the nanomaterial surface. As seen from Figure 2a there are some agglomerations of nanoparticles; this is due to sintering processes. As well as the nanoparticles possess high surface energies, so they tend to agglomerate and grow to larger assemblies [30].

Figure 2b shows EDX peaks of the synthesized magnetite nanoparticles. The observed peaks appear the existence of some elements as O, Fe, Ni, Mg, and Ag. These elements have the energies spectra in keV as it follows: (O: Kα=0.525), (Fe: Kα=6.4, Lα=0.705), (Ni: Kα=7.84, Lα=0.85), (Mg:

Kα=1.25), and (Ag: Lα=2.98, Lβ=3.35. There is no Kα for Ag in the figure since it appears at 22.16 keV and the devices limited to 10 keV). There are other spectra than the spectra of the constituent elements identified at the energies (2.3 and 3.3) keV. These are false peaks the appeared in the EDX spectra because of the automatic peak identification process. This process is sensitive to noise in the X-ray continuum that forms the spectral background because random groupings of background counts can mimic a characteristic peak [31].

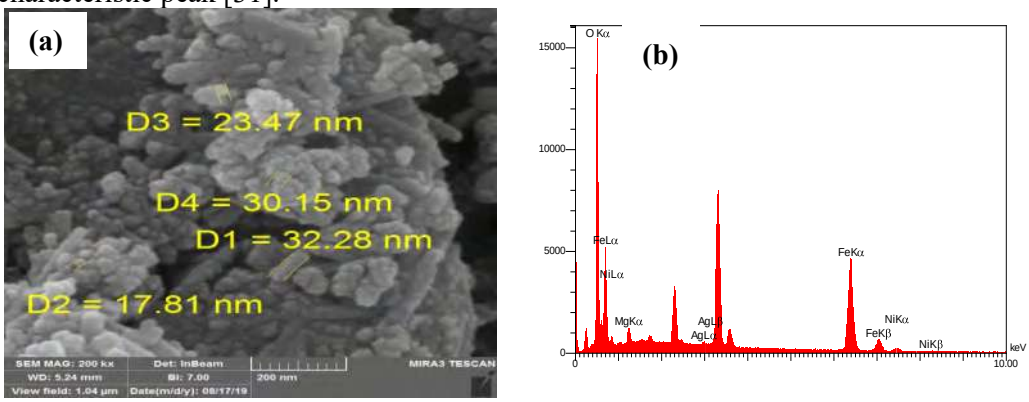

Figure 2. (a- SEM image, b-EDX spectra) of the prepared magnetite NPs.

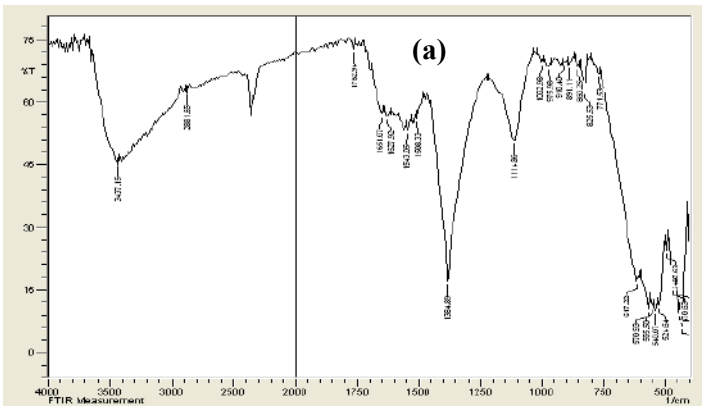
Figure 3 demonstrates the FT-IR absorption bands for the prepared magnetite NPs. In figure 3a for bare magnetite NPs there are strong characteristics, bands, at around 600 cm^{-1} due to (Fe-O) bond; this proves that the main phase of the synthesized NPs is the magnetite (Fe_3O_4) of spinel-type structure [16]. These characteristic peaks can be attributed to the lattice absorption of iron oxide [32]. There is also a small absorption band at 2360 cm^{-1} can be attributed to the CO_2 vibration. The broad absorption band at 3433 cm^{-1} indicated the existence of surface hydroxyl groups (O-H stretch) [16].

Figure 3b represents the FT-IR spectrum of (SF). Two characteristic absorption bands have been noticed. The first band is broad (1400-2000) cm^{-1} and may attribute to the bond (C=O) stretch. The other band is medium and sharp at around (3000 cm^{-1}) may attribute to the bond (C-H) stretch. Figure 3c represents the FT-IR spectrum of SF-coated magnetite NPs. A band has been appeared at around (1600 cm^{-1}) may concern to the (C=O) functional groups present in SF. In addition there is a band at around (3400 cm^{-1}) which is a boarder and more intense than those of the bare magnetite NPs (Figure 3a), can be attributed to (C-H) bond stretch in SF which, proves that prepared magnetite NPs were successfully coated with SF.



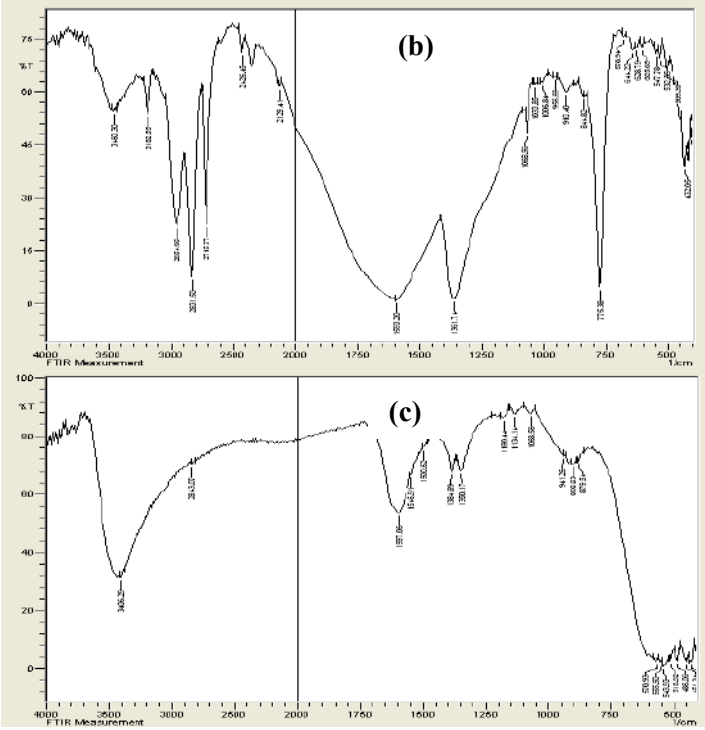


Figure 3. FT-IR spectra for a- bare magnetite NPs, b- SF, c- SF-coated magnetite NP

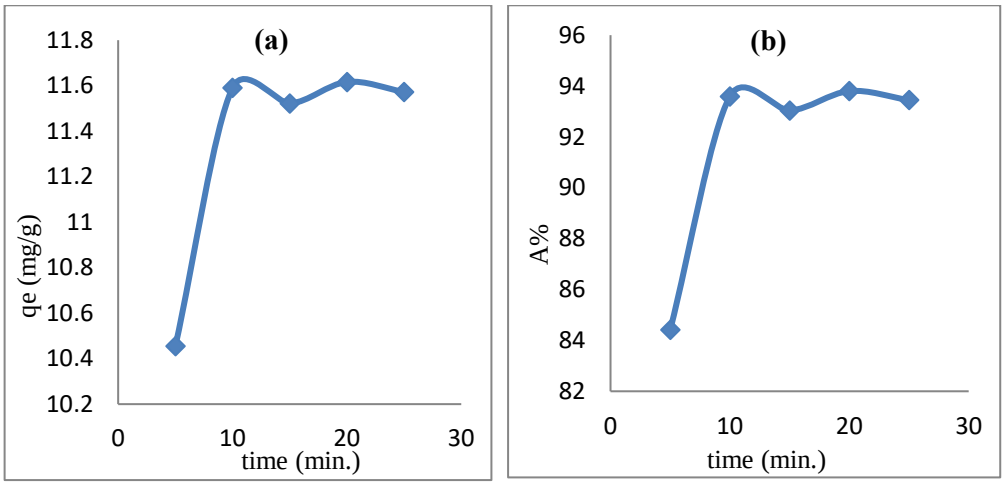
Table 1 lists the concentration (C_t) mg/ml, amount (q_t) mg/g, and removal rate (A%) values of Pb ions of the prepared SF-magnetite NPs. As shown by Figure 4, qt firstly increased then settled at approximately (11 mg/g) in (10 min) which represents the equilibrium time. The removal rate (A%) as has been seen by Table 1 and Figure 4 is high (93%), indicating the high efficiency of these NPs. This performance can be attributed to the ionic bond in SF that is easily broken in the solution emptying Na ions site. So the molecule of SF became a seeker for other cations in the solution and picks Pb ion rather than Na ion because Pb ion radius is bigger than Na ion radius so the selectivity for adsorbing Pb ions from the solution is higher than for other cations in the solution [33].

Table 1. Concentration, amount of Pb ions, and removal rate of the prepared SF-magnetite NPs.

Time (min)	C_t (mg/ml)	q_t (mg/g)	A%
5	0.0039	10.4542	84.4172
10	0.0016	11.5906	93.5936
15	0.0017	11.5220	93.0397
20	0.0015	11.6164	93.8015
25	0.0016	11.5725	93.4475

The adsorption of Pb ions from the wastewater samples (C and P) was done at the same conditions used before, but the time has been used is (10 min.). Table 2 lists the concentration of Pb ions (mg/ml), adsorption amount (mg/g), and removal rate of Pb ions from wastewater. The SF-magnetite

NPs



Figures 4. a- Equilibrium curve, b- Removal rate curve for the sample FM_6

showed an excellent removal rate with both samples giving (55%) For (C) and (100%) for (P). The contaminated wastewater sample (C) could have other particles that affect the removal of Pb ions since the prepared NPs have already shown a great capacity to adsorb Pb ions from a solution contains 25 ppm of Pb ions as has been proved in the above paragraph giving removal rate (93%). So the prepared SF-magnetite NPs could be a possible good adsorbent for other heavy metals in special and pollutants in general.

Table 2. Concentration, adsorption amount, and removal rate of Pb ions from wastewater of the prepared SF-magnetite NPs.

Wastewater sample	C_0 (mg/ml)	C_t (mg/ml)	q_t (mg/g)	A%
C	2.6127	0.0012	0.7198	55.100
P	0.2185	0	0.0011	100

1

6. Conclusion

SF-coated magnetite NPs ($SF\text{-}Ni_{0.31}Mg_{0.15}Ag_{0.04}Fe_{2.5}O_4$) have been prepared by the co-precipitation method. The crystal structure of the prepared NPs was confirmed by XRD and, it was matched with the standard pattern of the inverse spinel cubic iron oxide (Fe_3O_4) and have average crystallite size of 28.57 nm, the lattice constant of 8.32582 Å, and x-ray density of 5.2890 g/cm^3. The size of the prepared NPs was in the nanometer range as clarified by the SEM images and has an average crystallite size of 25.93 nm. By EDX spectra, the presence of the constituent elements was confirmed. The attachment of the SF molecules to the nanoparticle surface was proven by FT-IR spectra analysis. For adsorption of Pb ions from the prepared Pb $(NO_3)_2$ solution, a great adsorption capacity was shown by the prepared SF-magnetite NPs. That giving an adsorption amount (11.60 mg/g) that corresponds to the removal rate (93%) at equilibrium time (10min); while for adsorption of Pb ions from the wastewater samples (C and P). The prepared NPs showed an excellent removal rate for adsorbing Pb ion equals to (55% for C) and (100% for P). It was concluded that the crystal structure of SF has played an important role in the process of adsorption giving more sites to be filled by Pb ions; making the prepared NPs surface a possible adsorbent for other pollutants.

Abstract. In the present work, the nonlinear equation for a single-diode design of a photovoltaic cells is introduced. The mathematical model based on False Position Method (FPM) was used to determine the parameters of the voltage of the solar cell device based on the electrical equivalent circuit. The False Position Method currently presents to demonstrate the non-linear electrical behavior of this device. The proposed method is tested to solve the nonlinear example and the obtained results are used.

Keywords: False position method, iterations, absolute error, load resistance, mathematical model, nonlinear equation

1. Introduction

One of the purpose often practiced in applied mathematics and requires tired arithmetic is the solving of transcendental and algebraic equations (transcendental function). Any equation contains different forces of (x) or trigonometric or exponential functions or logarithmic or so-called (transcendental function)-nonlinear equation. In order to find the roots of such equations, there is no theoretical method or direct law for this point. The approximate numerical analysis is needed to obtain the results or the roots of these equations, and the results are uncontrolled and approximated compared to the theoretical results. The method of numerical results generally based on the accuracy of the error reached (degree of accuracy). However, the adopted numerical techniques is the best solution to find the approximate results, especially for nonlinear equations and difficult solved by theoretical techniques. However, there are many numerical techniques to solve these equations. The roots determined in numerical techniques can be calculated roughly by drawing or approximate the calculation when one see a difference in the function's value from negative to positive or vice versa. On the other hand, there is a cut of the function of the x −axis. Depending on the root's nature, found and numerical techniques adopted many natural choices and the most important of these methods: simple iterative method, Bisection Method, Newton Raphson and False Position Method [1-8]. Solar energy has been utilized to generate electricity in several applications including running of traffic lights, water desalination, street lighting, power plants, and the operation of many electronic apparatus for example calculators, clocks, vehicles, space stations and the operation of satellites [9]. There are many types of photovoltaic cell depending on the components and the materials preparation [10-16] including organic and inorganic solar cells [17-19].

The present work focuses on the proposed and characterized a new technique to give the roots in real case of a non-linear expression of the solar cell (single diode model). It describes according to the following points: in section two describes the characterizing of numerical model of an electric circuit based on photovoltaic cell; in section three establishing the root FPM are included while the discussion and conclusions of the results are listed in sections four and five. The acquired computations are implemented with Matlab program.

2. Properties of Photovoltaic Cell Equation (Single-Diode)

The design of solar cell's circuit scheme for single diode model is shown in Figure 1.

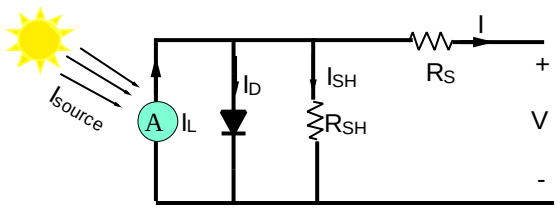

Figure 1. Solar cell's scheme

Applying Kirchhoff's current law on this equivalent circuit, yields

$$I = I_{ph} - I_D \quad (1)$$

$$I_D = I_0\left(e^{\frac{-V_{pv}}{nV_T}} - 1\right) \quad (2)$$

$$I = I_{ph} - I_0\left(e^{\frac{-V_{pv}}{mV_T}} - 1\right) \quad (3)$$

where:

I_{ph}: the photocurrent (A); I_0: reverse saturation current of the diode in(A);V_{pv} and$I$ are the delivered voltage and current respectively in (V);the thermic voltage $= 26mV$, according the equation($V_T = \frac{kT}{q} = 0.0259\ V$) at room temperature with air-mass = 1.5); m:$(1 < m < 2)$, k: Boltzmann constant= $1.38 \times 10^{-23} J/K$; T:$p-n$ junction's temperature(K); q: electron charge equal to $(1.6 \times 10^{-19}\ C)$ [**20**].

$$I_{ph} = I_{source} \quad (4)$$

$$I_D = I_s * \left(e^{\frac{V_D}{nV_T}} - 1\right) \quad (5)$$

Substitute Eq. 4 in Eq. 5 yields

$$(I_{source}) - 10^{-12}\left(e^{\frac{-V}{1.2*0.026}} - 1\right) = \frac{V}{R} \quad (6)$$

where: I_s reverse saturation current= $10^{-12}A$. In parallel, $V_D = V_{pv} = V$

Based on Eq. 6, the first derivative of it is needed in order to determine the $V$of the diode [21].

3. False Position Method (FPM)

The FPM is the most effective approach to find the root of a nonlinear function. It is a generalized from the Newton-Raphson method and does not require obtaining the derivative of the function. It has a super linear convergence.

For a given x_0 and x_1, x_l is first point of guess interval, x_u is first point of guess interval, ε is allowed error in calculation satisfy the equation $|x_{i+1} - x_i| < \varepsilon$, where ε is a very small number and $f(x)$is inter function, then
Find $x_2, x_3, x_4, \ldots, x_n$ using the following expressions

$$x_r = x_u - \frac{f(x_u) \times (x_l - x_u)}{f(x_l) - f(x_u)}$$
$$x_3 = x_3 - \frac{f(x_2) \times (x_2 - x_1)}{f(x_2) - f(x_1)}$$
$$\vdots$$
$$x_n = x_{n-1} - \frac{f(x_{n-1}) \times (x_{n-1} - x_{n-2})}{f(x_{n-1}) - f(x_{n-2})}$$

Advantages of FPM over other root finding methods are:
Its rate of convergence is faster than bisection method.
FPM is not needed to find the derivative of the function as in Newton-Raphson method and other methods [22].
The algorithm of the FPM can be describe as the following steps
Input x_l, x_u and ε
Compute $f(x_l)$ and $f(x_u)$
Compute $x_r = x_u - \frac{f(x_u)\times(x_l - x_u)}{f(x_l) - f(x_u)}$
Test for accuracy of x_2
If $|x_{i+1} - x_i| > \varepsilon$, set $x_l = x_u$ and $x_l = x_2$
Go to step 2
Display the required root as x_2

The approximate root of equation $f(x) = 0$ is the point $x_{i+1}$is considered according to the equation$\sigma = |x_{i+1} - x_i| < \varepsilon, |f(x_n)| < \varepsilon$(9)

where:ε: the absolute value of the function is a very small number. For convergence criteria, it was required that σ the distance between two consecutive iterates was less than 10^{-9}, the number of iterations represents by $n$and the solute value of the function represented by$f(x_n)$ [23].

4. Results and Discussion

Suppose the equation of the solar cell (single-diode) has obtained the following approximate solutions, and the Bisection method are applied with the two initial values$x_l = 0.9$and$x_u = 1$.
In Table 1, the False position method (FPM) with the input (x_l, x_u) and output x_2 values of the solution results and the absolute error function are obtained in the condition of $R = 1$ (load resistance).

Table 1. The voltage values of the solar cell with σ and εvalues using FPM.

Figure 6 shows the results using FPM technique.

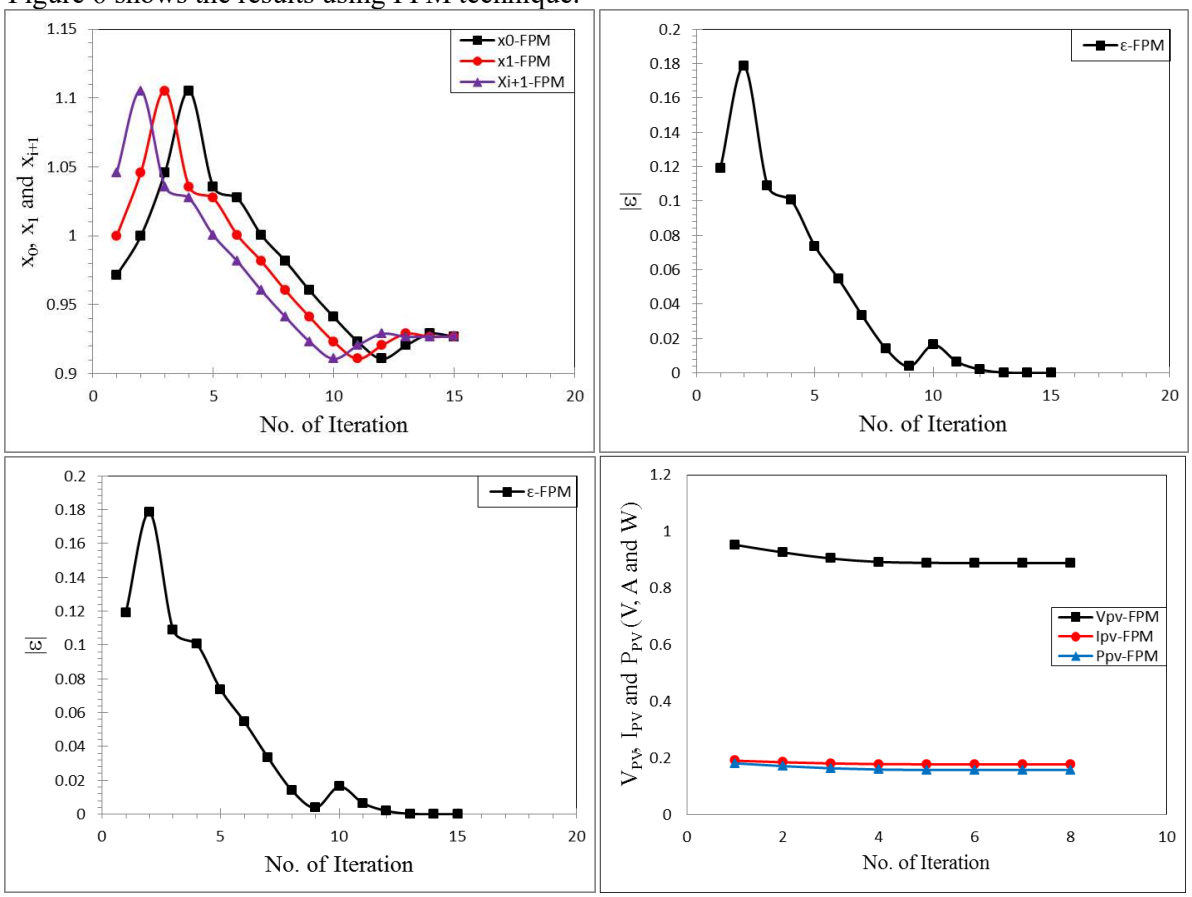

Figure 6. The results by using FPM method.

The plot of the number of iteration with ε plane and initial-output values proves that the proposed (FPM) method has a thirty iterations indicated a slow behavior. In addition, it is noticed that the suggested technique (FPM) has a behavior of the result in initial values $x_l \approx 0.9$ and $x_u = 1$ has tolerance as the smallest error.

In Tables (1-5), the proposed FPM technique is faster than other methods, and it has a less error after view the calculated iterations that depending on the efficiency investigating.

5. Conclusion

In the present work, numerical results of a single-diode (solar cell) in mathematical numerical formula were obtained. The basic advantages of the proposed (FPM) method are accurate approximate solution and a numbers of iterations produce simplicity.

Abstract: Electrical properties (carrier concentration, mobility, resistivity) of zinc oxide thin films deposited on glass substrates by (LPCVD) has been studied. Thermal annealing in air showed that ideal annealing temperature is about 250˚C. Films of copper oxide (CuO) and (CuO/ZnO) solar cell were prepared by vacuum deposition of copper films followed by thermal annealing. structural properties of the CuO films and I-V characteristics were studied upon thermal annealing and showed that a photosensitive (ZnO/CuO) heterojunction may be obtained by thermal treatment temperature about 500 ˚C.

Keywords: Cuprous oxide, spatial atmospheric ALD, ZnO/Cu_2O heterojunction, solar cell

1. Introduction

Solar cells (SC) based on oxide heterostructures have long remained outside the area of scientific interest on the part of researchers. However, at present time, a slowdown in the efficiency growth of both silicon and A_3B_5 semiconductor-based efficiency has become clearly visible, and the search for new materials for SC has begun actively. One of these materials is copper oxide – CuO. Being a straight-band semiconductor with a band gap of 2.2 eV, copper oxide also has a high absorption coefficient [1] and is characterized by p-type conductivity. In combination with a wide-band semiconductor, such as zinc oxide. It is possible to form a ZnO/ CuO heterojunction, which can be used to produce a solar cell with a theoretically achievable efficiency value of about 20% [2]. At the moment, an efficiency value of 4.1% has already been achieved for a ZnO/ CuO heterojunction-based SC [3]. ZnO has unique properties for instance a wide band gap of ~3.37 eV [4], high exciton binding energy (~60MeV) [5], effective ultraviolet photoluminescence, high optical transparency in the visible range more than (80%) [6], and high electrical conductivity. Currently, zinc oxide is used to create various sensors and detectors, piezoelectric devices, as a transparent conducting contact in solar panels and other devices [7]. The growing interest in zinc oxide-based heterojunctions is associated with wide opportunities for practical applications. In particular, a p-n transition based on n-ZnO and p-CuO is promising, so methods for obtaining ZnO/CuO hetero-junctions are actively developing [8,9,12]. In this paper, the properties of ZnO films deposited by the LPCVD method and (ZnO/CuO) structures are studied by spraying the copper film onto the substrate followed by thermal annealing treatment to improve the I – V characteristics.

2. Experimental

Zinc oxide films were obtained by low pressure chemical vapor deposition (LPCVD). Diethylcinc ($(C_2H_5)_2Zn$), or DEZ, and deionized water were used as precursors, the concentration ratio was ($\frac{H_2O}{DEZ} = \frac{5}{6}$). a gas mixture of 2% ($B_2H_6$) in hydrogen was used for doping ZnO films with boron. The process was optimized sequentially by optimizing the temperature and pressure, and then by optimizing the gas flow ratio. Pulsed light annealing treatment of (ZnO/CuO) structures was obtained in an installation containing 6 halogen lamps with a power of 1 kW for (60sec). The wavelength region (800-1100 nm) is ~80%, then gradually decreases to ~60% at 600 nm and drops to zero in the self-absorption region of ~370 nm. In this case, the optical transmission spectrum shows optical interference in the film in the wavelength range of 600-1100 nm, which indicates a high uniformity of the film thickness. The electrical parameters of ZnO films were determined by measuring the resistivity and carrier concentration using the Hall effect at room temperature using a four-probe method in the van der Pau configuration on an HMS-3000 (Ecopia) installation with a 0.55 T magnetostatic magnet. To study the electrical properties of ZnO films on glass substrates, they were cut into square samples with dimensions of 10×10 mm. Measurements of the electrical properties of a set of ZnO samples cut from a single substrate showed a very small variation of electrical parameters in the initial samples within 5%.

3. Results and discussion

The parameters of the initial ZnO samples Were: electron concentration n~1×10^{20} cm^{-3}, carrier mobility 30 $cm^2/V.$ s, resistivity 2×10^{-3} Ω.cm, sheet resistance ~12 Ohms. The effect of thermal processing in the temperature range from (200°C- 500°C) is studied on the sheet resistance of ZnO. It is found that the sheet resistance of ZnO films do not change until the annealing temperature is 200°C, then in the temperature range from 250ºC to 500ºC, the resistance of the films increases, apparently, annealing in air reduces the concentration of oxygen vacancies and causes growth the concentration of adsorbed oxygen at the grain boundaries, which leads, first, to the capture of free carriers at the grain boundaries and, accordingly, causes a depletion of the volume. Second, the appearance of a charge at the grain boundaries leads to strong scattering of free carriers, see Figure 1.

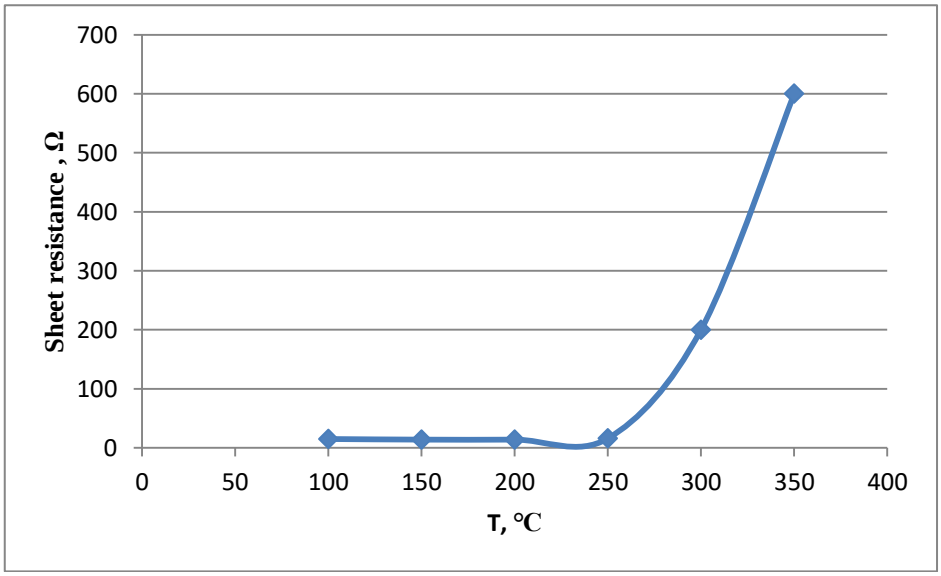

Figure 1. Dependence of sheet resistance of the ZnO film on the annealing temperature.

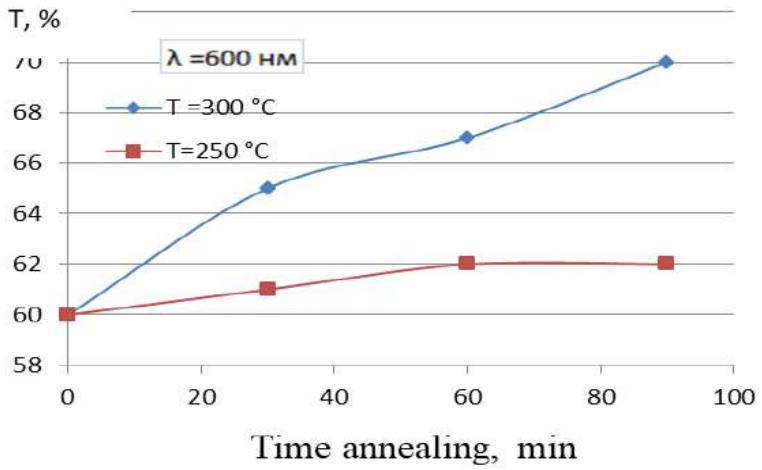

Figure 2. Optical transmittance (ZnO) as function of time annealing at a wavelength of 600 nm, thickness 1600 nm at different temperatures (250 °C and 300 °C).

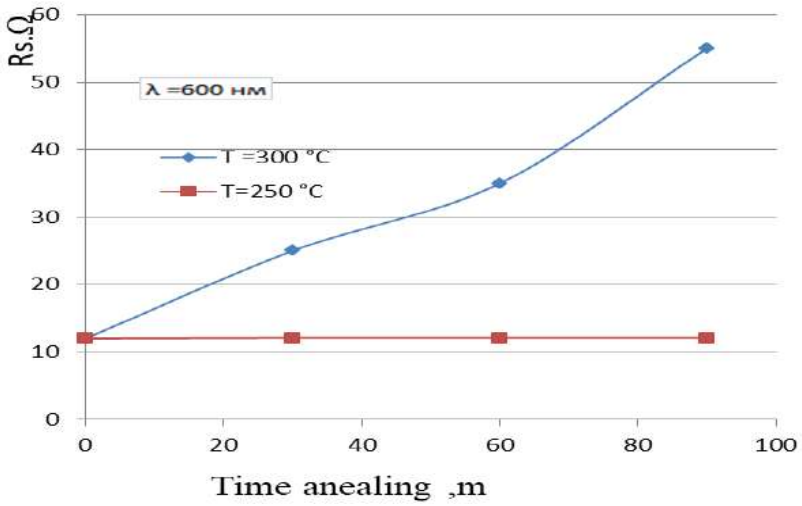

Figure 3. Sheet resistance of (ZnO) as function of time annealing at a wavelength of 600 nm, thickness 1600 nm at different temperatures (250 °C and 300 °C).

In order to obtain opaque electrical and optical characteristics of ZnO films, it is necessary to avoid long-term treatments at high temperature, see, (Figures 2 and 3). To obtain (ZnO/CuO) structures, thin copper films were sprayed on the substrate surface by magnetron sputtering at a pressure of 10^{-5}bar. To control the optical properties, clean glass substrates were attached next to the ZnO samples. After deposition, the films of CuO and the structures (ZnO/CuO) were annealed to improve the electrical properties and I-V characteristics.

Figure 4. shows x-ray Images of copper thin films deposited on ZnO substrates and annealed at various temperatures (220 ˚C -500 ˚C) in air. After annealing at 220 ºC, an intense diffraction peak appears at $2\theta=36.6^{\circ}$ which can be attributed to (111) reflection of the Cu_2O cubic phase. At higher temperatures, this reflex becomes less intense, while the peaks at angles 2θ =35-40°, which correspond to the reflexes (110), (002), (111) the monoclinic phase of CuO becomes more intense. Thus, x-ray diffraction results correlate with optical absorption data. From these results, it can be concluded that

annealing of copper films at 220 ˚C -550 ˚C, leads to form a mixed phase of (CuO-Cu_2O), while the contribution of the phases depends on the temperature and time annealing, see (Figures 4 and 5).

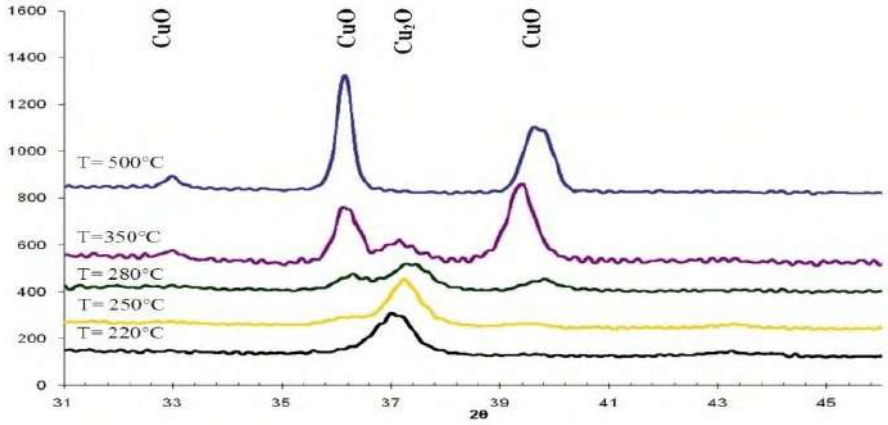

Figure 4. Composition and structure of copper thin films obtained by thermal oxidation of copper.

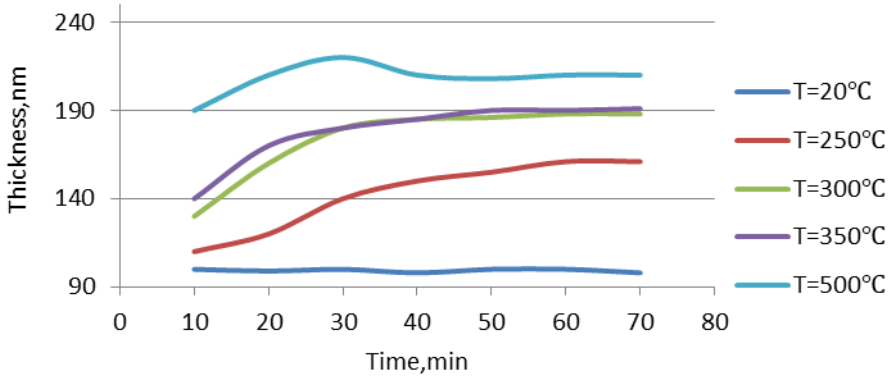

Figure 5. Changes in thin films thickness depending on the annealing time.

The I-V characteristics of (ZnO/CuO) structures obtained by deposition of copper thin films on the surface of ZnO layers, improve volt-ampere characteristics were formed during thermal annealing of copper films at 200-500°C. It was observed that the I-V characteristics of (ZnO/CuO) of the samples depend on the time of thermal annealing and temperature. The initial structure which obtained before annealing showed that the I-V characteristics were close to ohmic, and a weak asymmetry of forward and reverse characteristics was observed. This may indicate a critical role for the tunnel current [11]. However, we were observed after thermal annealing treatment in the range (200 ˚C -500 ˚C) leads to decrease in leakage currents and an increase in the value of the potential barrier. This indicates a significant contribution of tunnelling processes through surface by structural defects [10,11] and allows us to improve I-V characteristics as Figure 6 showed.

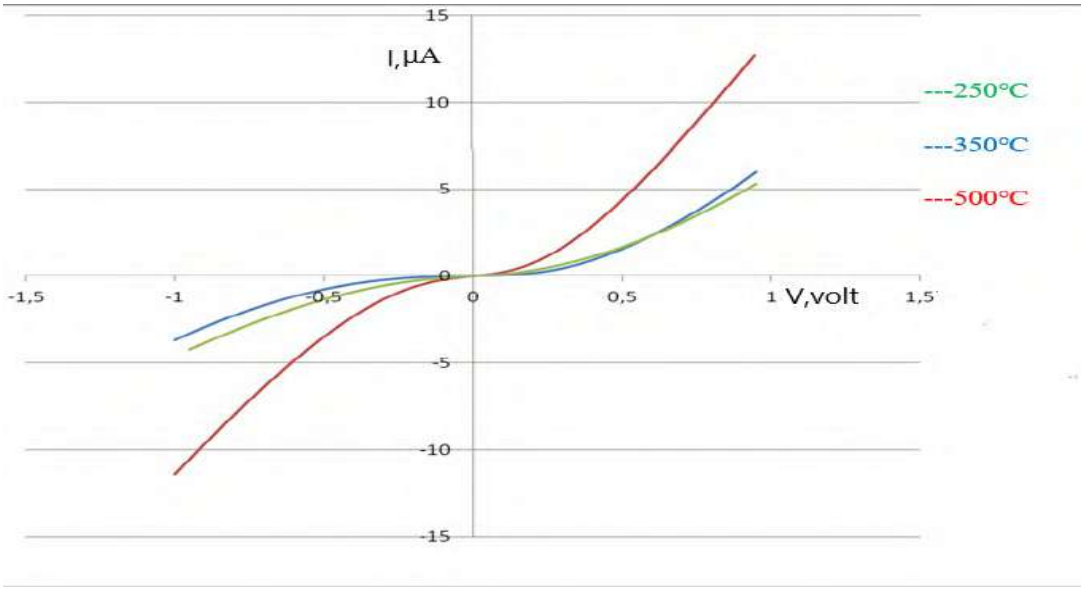

Figure 6. I-V characteristics of (ZnO/CuO) hetero structures after annealing for 60 sec at temperatures (250˚C, 350˚C and 500˚C).

The solar cell structures (ZnO/ CuO) obtained after thermal annealing at temperature of (500˚C) show a typical I-V characteristic when the forward current increases. The dominance of multi-stage tunnelling and recombination processes through traps in the (ZnO/ CuO) structure is evidenced by the literature data on temperature dependences of the volt-ampere characteristics [10]. The process of tunnelling through a thin layer of bulk charge is also significant, so to reduce the non-ideal factors and suppress tunnelling leakage currents, a layer of high-resistance ZnO is created at the border of the hetero-structure [11]. Thus, short annealing times and temperature annealing improved the electrical and optical properties of ZnO and allow obtaining (n-ZnO/p-CuO) heterojunctions.

4. Conclusions

The effect of thermal treatment on the electrical and optical properties of ZnO films obtained by the PLCVD method is investigated. Annealing of ZnO films at temperatures above 200 ˚C causes degradation of electrical properties, the carrier concentration and mobility decrease, and the sheet resistance increases. Subsequent annealing of the samples in air leads to a significant restoration of the electrical parameters. It is established that the method of deposition of thin layers of copper on ZnO films with subsequent rapid oxidation in air for 60 sec. At temperature ranged (250 ˚C -500 ˚C), a photosensitive thin-film ZnO/ CuO heterojunction was obtained.

Abstract. In this work, radon gas concentration in (35) samples of soil collected from Karabuk University in Turkey was measured by using nuclear track detector (CR-39). The content of radium, the rate of surface exhalation and the rate of mass exhalation have been assessed. The concentrations of radon were varied from (16.348 $Bq.m^{-3}$) to (196.988 $Bq.m^{-3}$). Results indicate that the equivalent content of radium varied from (0.386245 $Bq.kg^{-1}$) to (4.654255 $Bq.kg^{-1}$). The exhalation rate for surface varied from (0.002007 $Bq.m^{-1}.h^{-1}$) to (0.023031 $Bq.m^{-1}.h^{-1}$). The exhalation rate for mass varied from (0.000319 $Bq.kg^{-1}.h^{-1}$) to (0.00366 $Bq.kg^{-1}.h^{-1}$). All the obtained results found to be less than the corresponding limits for the world. Thus, based on the radon gas concentration and radiation, the equivalent content of radium (C_{Ra}), exhalation rate for the area (E_{Area}) and exhalation rate for the mass (E_{Mass}) in this area have no risk to the human's health.

Keywords: Radon gas, nucleartrack detector CR-39, soil, equivalent content of radium,exhalation rate for surface,exhalation rate for mass.

1. Introduction

Radon gas (^{222}Rn) is the most variable and largest radiation that contributed to public exposure. It was found that the ratio of radon and it's daughters dose per year about (55%) of natural public exposure by inhalation of air, which the high levels of it can cause lung cancer [1] because Radon is a radioactive gas (alpha particle emitter) hasa decay constant of (0.1812 day^{-1}) with $t_{1/2}$ of (3.825 days) [2]. When radon exposure increased, the risk of lung cancer will increases, which has a linear relation with doses, it has been found that the risk of lung cancer increases (16%) per every (100 Bq/m^3) increase in radon concentration[3].The ^{238}U series generate radon ($^{222}_{86}Rn$) as a daughter of radium(^{226}Ra), which has another isotopes are the thoron (^{220}Rn) and actinon (^{219}Rn) which are daughters of^{232}Th and ^{235}U series, respectively[4]. Radon is an inert gas heavier than the air, without any color and smell or taste, which is usually stay close to the ground floors [5]. Two different methods were used to measure the radon concentration. The first one is the passive method by integrative sampling for long time exposure using a suitable detector (like CR-39 in this work) and the second method is the continuous active radon sampling (like continuous radon monitor), the first

method requires no electrical power as in the case of the sconed [6]. There are many studies about radionuclides and radon concentration emitted from soil samples in Turkey, which starts in 1983[7] by using Gamma spectroscopy and CR-39 detectors (for indoor and outdoor radon), there are two studies for Karabuk Governorate[8,9], but for Karabuk University area, this is the first study about radon concentration outdoor in it.

2. Experimental Part

2.1. Calculation of Radon gas concentrations

Thirty-five soil samples were collected from Karabuk University as shown in table-1 and Figure-1. These samples were dried by the oven (at a temperature of 80°C for 2h)and grinded into a powder with size of (200 μm) by using a sieve,then 10 gm was taken for exposure.

The sealed-cup technique was used in this work, the sample a weight of putin a small cup,then covered with a large cup that contain CR-39 detector with a thickness of(250 μm). And an area of ($1cm^2$) at the top of it,as shown inFigure-2,the exposure time was (60) days to attained secular equilibrium. Then the chemical etching for the detectors was current by using (NaOH) solution with the normolity of (6.25N) at(60^oC) for five hours.

The tracks in CR-39 of alpha particles concentration emitted from Radongas from soil samples were measured using an optical microscope (Nikon type 168 Japan made) with amagnification of(400X). The numbers of the tracks were measuredto get track density (ρ) ,which is given as[3]:

$$(\rho) = \frac{N_{ave}}{A} \quad (1)$$

WhereN_{ave} is an average number of total tracksand A is an area of field view. The Radon gas concentration in the soil samples was obtained by the comparison between track densities registered on the detectors of the samples and that of the standard soil samples which are shown in Figure (3), using the following relation [10]:

$$C_X = C_s\left(\frac{\rho_x}{\rho_s}\right) \quad (2)$$

$$C_x = \frac{\rho_x}{slope} \quad (3)$$

WhereC_X is alpha particles concentration in the unknown sample,$C_s$is the alpha particles concentration in the standard sample.ρ_x is track density of the unknown sample (track/mm^2) and ρ_s is track density of the standard sample (track/mm^2).

2.2 Calculation of Radiation indices

The equivalent content of radium in the soil sample in the unit (Bq/kg) is given as[11]

$$C_{Ra}\ (Bq.kg^{-1}) = \frac{\rho\ .\ h\ .\ A}{K\ .\ T_e\ .\ M} \quad (4)$$

where, ρ is track density (track/mm^2),A is the area of the surface sample (0.001589 m^2),K (calibration constant) equal to the slope/exposure time(7.026/60=0.117), h is the distance from the surface of the sample to the detector(13.5 cm), M is sample mass of (0.01kg), T_e is the effective exposure time(h),which given as[11]:

$$T_e = T - \frac{1}{\lambda\left(1-e^{-\lambda T}\right)} \quad (5)$$

Whereλ is the decay constant of radon (0.1814day^{-1}) and T is exposure time.

The area surface exhalation rate and the mass exhalation rate are given as[11,12]

$$E_{Area} = \frac{C\ .\ V\ .\ \lambda}{A[T+\lambda^{-1}(e^{-\lambda T}-1)]}(Bq.m^{-2}.\ h^{-1}) \quad (6)$$

$$E_{Mass}=\frac{C.V.\lambda}{M[T+\lambda^{-1}(e^{-\lambda T}-1)]}(Bq.kg^{-1}.h^{-1}) \quad (7)$$

WhereCis the radon activity or integrated radon exposure ($Bqm^{-3}h$), V is volume of cup (m^3), T is Time of exposure (hrs), M is Mass (kg) of the sample in cup, λ is the decay constant for radon (h^{-1}).

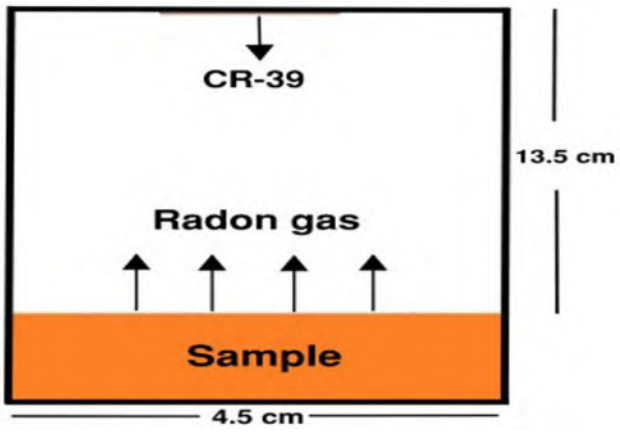

Figure 2. The sealed-cup technique for radon exposure.

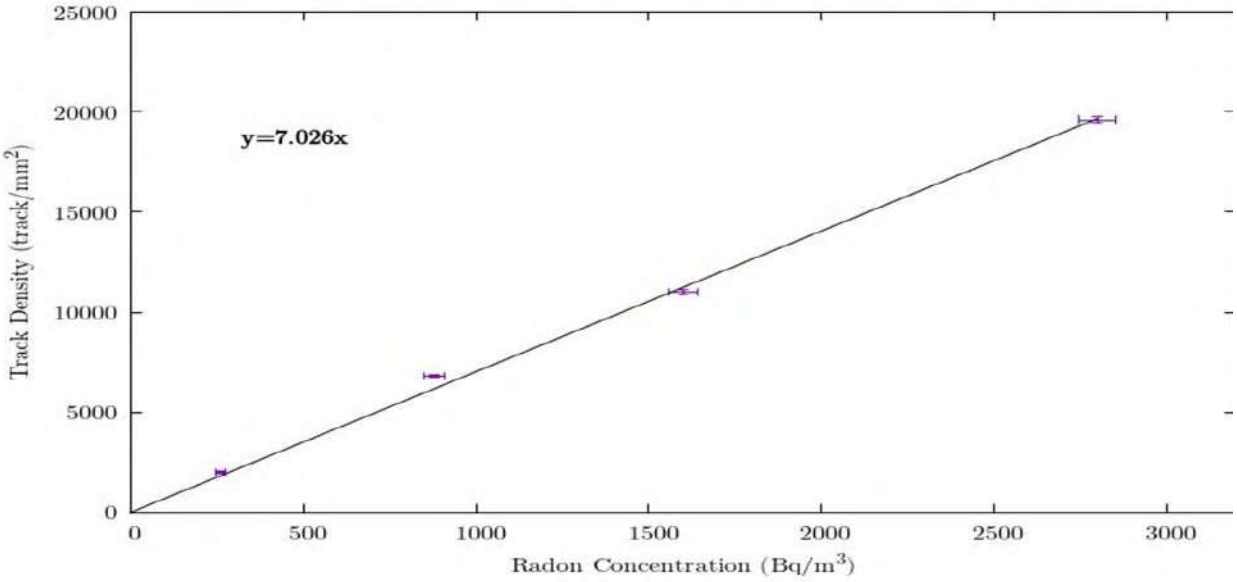

Figure3. The relation of track density and radon concentration for standard soil samples.

3. Results and Discussion

The results of radon concentrations emitted from soil samples selected from Karabuk University, was obtained by using the equation (3) are presented in table (1). From this table, it can be noticed that the highest radon concentration was found in a Stadium soil sample (196.988 Bq/m^3), while the lowest value was found in TOKI-1(The residential complex) equal to (16.348Bq/m^3).We also find that there are some values of radon concentrations close to the highest value, which is in the Science Faculty (TCFB1) and Social Centre (SC) soil samples (172.467Bq/m^3) and (170.424Bq/m^3) respectively, that means they are the same soil, although that the radon concentration in fertilizer sample was (142.329 Bq/m^3) and for the original soil samples (106.441 Bq/m^3), which is in agreement with other studies that done by other researchers like Ereeset al in 2006 for Western Turkey[13],Kamand Bozkurt in 2007 for Kastamonu[14], Kam et.al., in 2010 for Çanakkale[15],Kurnazet. al., in 2011 for Trabzon[16], Tabaret. al., in 2013 for Dikili[17], Sogukpinaret., al., in 2014 for Eskisehir[18],Ozen et. al., in 2018 for Rize[19] and Asliet. al., in 2019 for Karabuk[9].However, all results of radon concentrations in this work were less than the recommended value of (200 Bq/m^3) and certified by (ICRP, 1993)[20]. Table 2, presents results for radiation induces like the equivalent content of radium ranged from (0.386245) to (4.654255) Bq/m^2.h,which were to be less than the permissible value of (370 Bq/kg) as recommended by the Organization for Economic Cooperation and Development[21], the exhalation rates for the area were varied from (0.002007Bq/m^2.h) to (0.023031Bq/m^{2}h) and exhalation rates formass varied from (0.000319) to (0.00366)Bq/kg.h.It should be mentioned thatthe observed values of the radon exhalation rate in thepresent work were below the world average of (2.5 Bq/m^2.h)[22].

Table 2. The effective radium content, area surface exhalation rate andmass exhalation rate.

4. Conclusions

Radon concentration, radium content, exhalation rates for the area (surface) and mass were obtained for selected soil samples collected from different locations on Karabuk University in Turkey. The results were found to be less than their corresponding permissible and certified world values. Thus, the present results revealed that the area is safe as far as the health effect is concerned, except the highest values which within the statistical ranges, the approximate values of the radon concentration refer to the soil of one source, which is transferred from another place for the purposes of agriculture, especially since the concentration values of the radon emitted from the original mountain the soil was far from it,which in agreement with other studies. From this, we conclude that we must know the sources of these soils and examine them radiographically before using them in agriculture or costruction material and conduct other tests, such as X-rays fluorescent for these soils to find out their composition, which is an evident through the shape and the color forthem,that they are transported soils.

Abstract. This paper reports theoretical treatment to drive the general equation for laser threshold power (P_{pump}^{th}), the efficiency (η) and the laser out power (P_{out}) in thin disk laser with a quasi -three –level pump plan by using the analytical solution of the rate equation for this laser system. In order to find a numerical solution, MATLAB program has been used. When a diode pumped high power, continuous wave to the Nd^{3+}: YAG thin disc laser operated in a quasi-three-level. The pumping wavelength was (808 nm) and the laser wavelength was (946 nm) at Nd^{3+} doping concentration of 0.6 at %. While at (M^2 = 1.005), this laser is operated in a single mode, all the laser output power and efficiency have increased with increasing the pumping power.

Keywords: laser, thin disc laser, diode pumped Neodymium, quasi three level lasers.

1. Introduction

The thickness of the crystal is small compared with the diameter of a thin disk and its coated with high reflectivity on one side of its faces for both lasing and pumping wavelength, fixing on a heat sink to remove the excess heat that appear on the disk [1]. If we assume that there is a large heat transfer coefficient over the whole region, then a temperature field inside the crystal is naturally equal to the temperature with the axis [1,2]. The disc can also be pumped by laser valves either longitudinally or radially. By using multiple passages for the pump radiation through the disk to increase the absorption of the pump's certification of a specific crystal thickness [2]. This disc can fit the resonator as false or like a folding mirror. This design can convert lasers in the range of several watts to kilowatts, as shown in Figure 1. The power volume can be increased by increasing the diameter of the pump to the disk at a constant pumping power density [2,3].

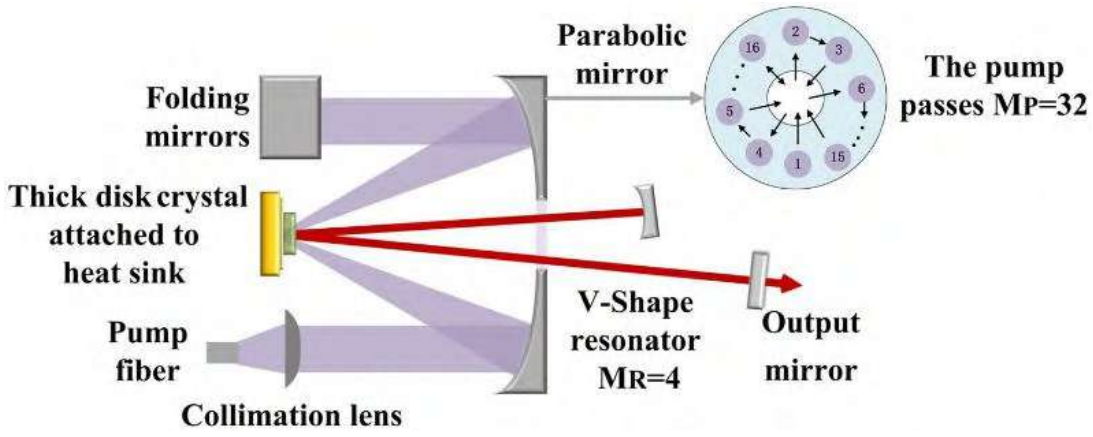

Figure 1. Multi-pass pumping in a Yb^{3+}: YAG thick-disk laser [14].

2. Analytical model

A quasi-3-level active medium, which is also termed a quasi-4-level active medium, it is characterized by being a large thermal count, low laser level. This means that when the temperature of the system with the four levels changes, it changes the properties of the laser, since at thermal equilibrium the laser does not contain a community, and thus the lower laser is filled in its entirety at thermal equilibrium [2]. The characteristics of the laser between the real 4-level system and the quasi-three-level system produce a major difference through re-absorption losses at the wavelength of the laser, and this leads to an increase in the three-dimensional losses in the resonator thus increasing the laser threshold [1,2]. The energy level system of Nd: YAG consists of stark split $I^4_{9/Z}$ ground state and $F^4_{3/Z}$ excited state. Because there is a small division of energy for each manifold, it is assumed that the relaxation times for the energy level within the manifold are also very small as shown in Figure 2. [2,5].

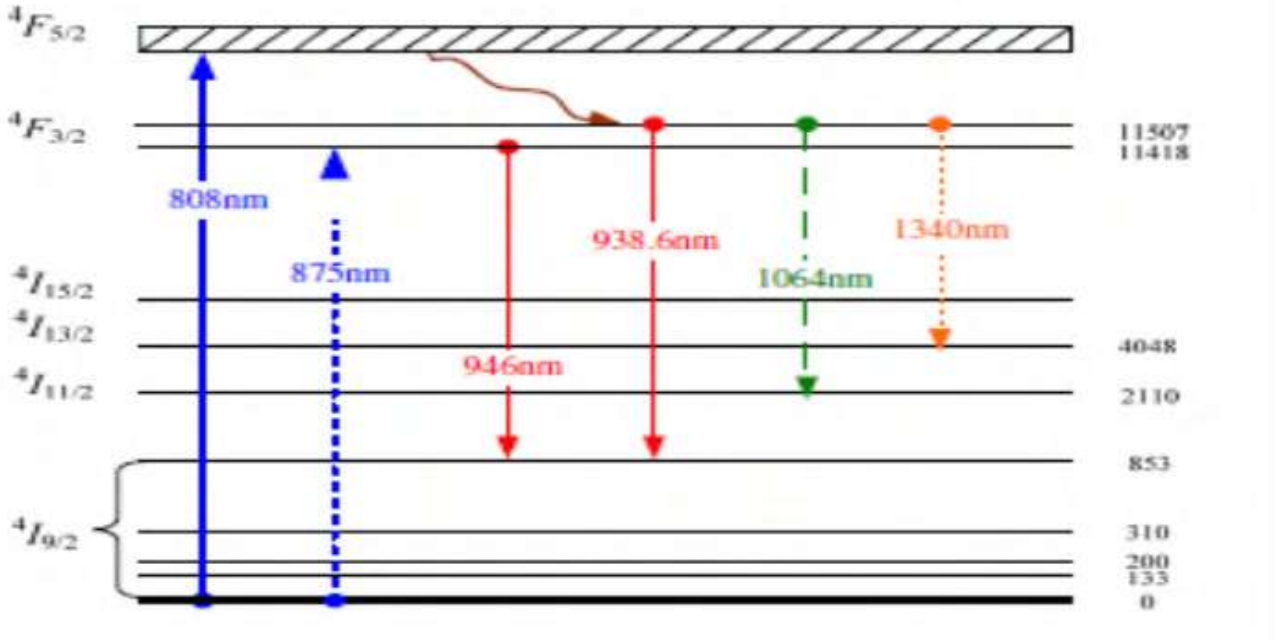

Figure 2. Energy level scheme of quasi three level Nd^{3+}: YAG [5].

Figure 2 illustrates the energy scheme for a Nd^{3+}: YAG crystal, where pumping wavelength (λ_p= 808nm) and lasing wavelength (λ_L=946nm). F_{1i}(i=1,2) and f_{0j} (j=1,2,3,4,5) act as a Boltzmann factors which refers to the occupation for the lower and upper manifolds, respectively.

$f_{1i}= \frac{exp\,(-\frac{E1i}{kT})}{\sum_{p=1} \quad expexp(-\frac{E1p}{KT})}$ ……(1)

$F_{0j}= \frac{(exp\,(-E0j/KT))}{\sum_{q=1} \quad exp\,(-\frac{E0q}{KT})}$……(2)

where (KB) Boltzmann occupation factor (T) is the absolute temperature. (E_{1i}) (i=1 , 2) describe an energy to each stark level of excited divergent and E_{0j} (j=1 , 2 , 3 , 4 , 5) describe an energy to each stark level of the ground divergent.

3. Steady state Rate Equation.

Average equation for two divergent system is given by [2,4]:

$\frac{dN_{up}}{dt} = \frac{I_p}{h\nu_p}\alpha_p - \frac{I_L}{h_{\nu L}} g_L M_L - \frac{N_{UP}}{\tau}$ ……(3)

$\frac{dI_L}{dt} = I_L(g_L M_L d - \delta)\frac{c}{2L_{opt}}$ …… ……..(4)

$g_L = (\frac{N_{UP}}{X_L} - N)\sigma L$ ……(5)

$X_L = \frac{f_{low}^L}{(f_{up}^L + f_{low}^L)}$ ……(6)

(N_{up}) represent the ion density in upper divergent , (I_P) is a medium pumping intensity through the crystal , (I_L)It is the energy intensity of the laser radiation scattered inside the cavity. (M_L) is the number of laser passing in the crystal per one resonator round trip, (τ) is The duration of the excitation state. (C) Is the speed of light in a vacuum, (L_{OP}) Optical length on the lumen. (d) Is the thickness of the crystal, (g_L) is a laser gain coefficient. (σp) and (σ_L) Cross sections represent effective absorption at (808 nm) and (946 nm) , respectively (N) is the total ionic density , f_{low}^L and f_{up}^Lrepresent the Boltzmann occupation factor in the lower and upper divergent for the laser level , respectively[2,4].

δ It is the loss of the round trip and can be described by [4]: [4]:

$\delta = -Ln(1 - Tr) - Ln(1 - \gamma)$ ……..*(7)*

where (Tr) the coupler is moved the output

Tr = $1 - R2$ … … … … … … … … … … … … … … … … … … (8)

γ) Calculate residual losses, such as those due to dispersion during one round-trip trip in the bore. *)*

When the pump intensity is greater than the intensity of the pump, the gain coefficient, the density of the ions in the upper manifold of the pump irradiation can be given by solving the steady-state rate equation:

gL = $\frac{\delta}{MLd}$……..(9)

N_{UP} = X_L (N+ $\frac{gl}{\sigma l}$)……(10)

Furthermore, on the basis of a multi-pass pumping system, the absorbed pump intensity (I_{abs}) and the absorption efficiency (η_{abs}) are given by[2,4] :

$I_{abs} = I_P \alpha_P d = I_{pump}\eta_{abs}$ ……(11)

$\eta_{abs} = R_P(1 - \exp(-M_P\alpha_P d))$……(12)

where Ipump is the input intensity (R_P) is The total reflection of the multi-pass pumping system, (M_P) the number of passes of the pump, and (αp) is the absorption coefficient. , and therefore, the laser intensity in the cavity (I_L) , the pumping threshold intensity (I_{pump}^{th})

output laser intensity I_{out} can be obtained by ($\frac{dN_{up}}{dt}$The output

IL = $\frac{V_L}{V_P}\frac{\eta_{abs}}{\delta}(I_{pump} - I_{pump}^{th})$ ……(13)

$I_{pump}^{th} = \frac{h_{vp}}{\tau}\frac{N_{UP}d}{\eta_{abs}}$ ……..(14)

And , the pump power , pump threshold power , and the laser power can be obtained by[2] :

PL= Ap IL …(15)
Ppump= ApIpump …(16)
P_{pump}^{th}= ApI_{pump}^{th} …(17)
Where (Ap) is the given pumping area
Ap = π (rp)^2 …(18)
(r_p) is pump radius , the beam quality factor is obtained
$M^2 = (\frac{a\, rp}{rf})$ …(19) [6]
(r_f) is the radius of a fundamental mode (TEM00) , the output laser power
Pout= Tr PL …(20)
Pout= $\frac{V_L}{V_P}\frac{Tr}{\delta}\eta_{abs}\,(P_{pump} - P_{pump}^{th})$ …(21)
Or
Pout= $\frac{\lambda_p}{\lambda_L}\frac{Tr}{\delta}\eta_{abs}\,(P_{pump} - P_{pump}^{th})$ …(22)
Where the laser extraction efficiency [4]
η_L= 1- $\frac{P_{pump}^{th}}{P_{pump}}$ …(23)
And . [2]
$\eta = \frac{\lambda_p}{\lambda_L}$ …… (24)
the output laser power can be
Pout= $\frac{Tr}{\delta}\eta\eta_{abs}\eta_L P_{pump}$ …….(25)

4. Results and Discussion.

In this paper, the results of the numerical solution by using Mat lab for the output laser power and efficiency for a quasi-three level of Nd^{3+}: YAG thin disk laser. The values of a coefficients for thin laser used in a Numerical solution illustrate in the Table 1.

Table 1. The value of a parameter for **Nd^{3+}: YAG** thin disc laser.

parameter	value	unit	Ref.
λp	808x10^{-9}	m	[5,7]
σp	6.7 x 10^{-24}	m^2	[5,7]
αp	1.83 x 10^2	m^{-1}	[7]
λL	946 x 10^{-9}	m	[5,7]
σL	3.7 x 10^{-4}	m^2	[5,7]
ɤ	0.02	---	[7]

The first step in the numerical solution was determine the operation Nd^{3+}: YAG thin disk laser of the type of the single-mode transverse or multi-mode transverse calculated (M^2) by equation (20) and (P_{pump}^{th}) by equation (18) for two values of radius of the pumping beam falling on the thin disk (r_p) as shown in Table 2.

Table 2. The values of (M^2) and (P_{pump}^{th}) to the of the radius of the pumping falling on the thin disk (r_p).

Parameter	Single-mode transverse	Multi-mode transverse	Unit
$\mathbf{r_p}$	230*10^{-6}	727*10^{-6}	M
$\mathbf{M^2}$	1.005	10.070	-
P_{pump}^{th}	2.549	25.539	W

Figure 3 illustrates the shape of the relationship between (p_{out}) and (p_{pump}), (p_{out}) is calculated by equation (26). In both modes, the laser output power increased with increasing of the pumping power, and the (p_{out}) is the highest values in a single mode operation.

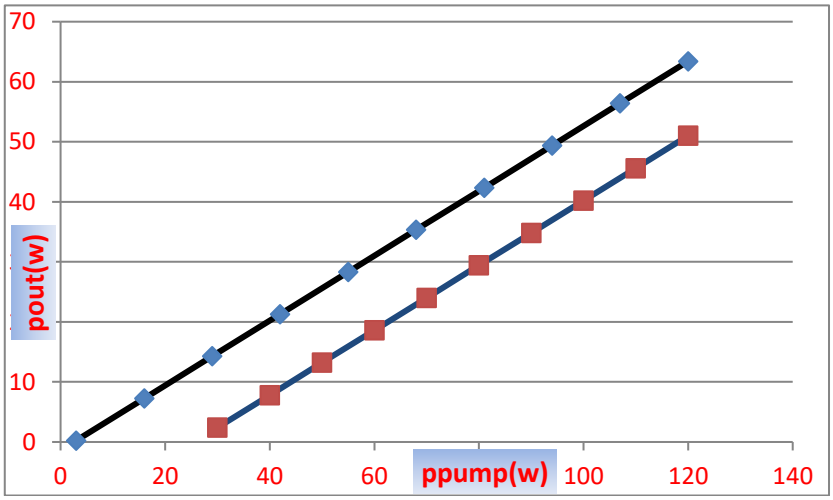

Figure 3. The relationship between (p_{out}) with (p_{pump}) in both modes.

Finally, the relation between the efficiency (η) and (pump) in both modes is shown in Figure 4. It is found that the efficiency of this laser increased with the increase of pumping power, and the values of (η) in single mode is highest.

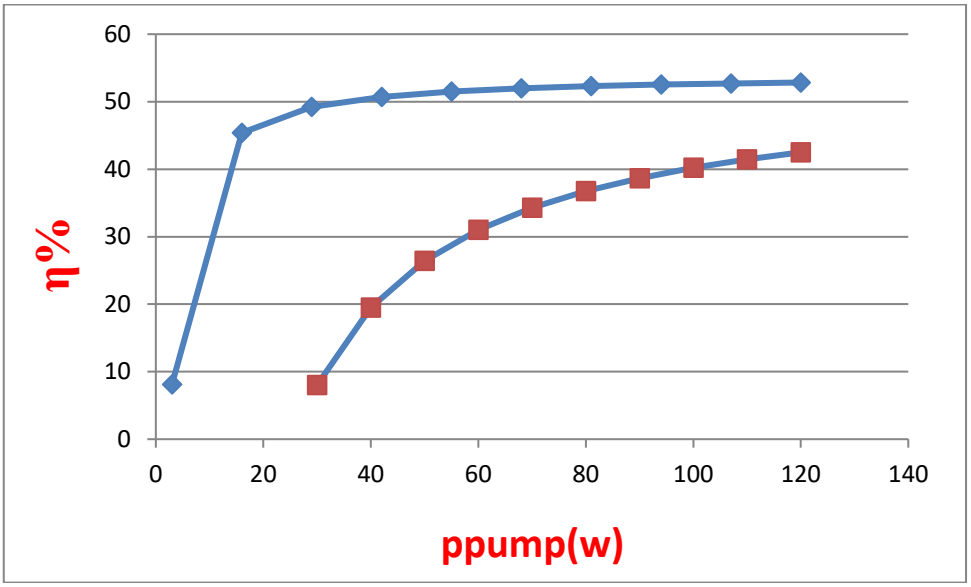

Figure 4. The relation between efficiency (η) and pumping power (P_{pump}) in both two modes.

5. Conclusions

In this paper, Nd^{3+}: YAG thin disk laser, were operated in a quasi-three-level system, at wavelength pump ($808*10^{-9}$ m) and wavelength laser ($946*10^{-9}$ m). The laser output power and efficiency are increased with pumping power, and the values of all (p_{out}) and (η) in a single mode operation are highest than the value in a multi-mode operation for this design of laser.

Abstract. The compound $Fe_{0.5}Co_xMg_{0.95-x}O$ where (x= 0.025, 0.05, 0.075, 0.1) was prepared via the sol-gel technique. The crystalline nature of magnesium oxide was studied by X-ray powder diffraction (XRD) analysis, and the size of the sample crystals, ranging between (16.91-19.62nm), increased, while the lattice constant within the band (0.5337-0.4738 nm) decreased with increasing the cobalt concentration. The morphology of the specimens was studied by scanning electron microscopy (SEM) which shows images forming spherical granules in addition to the presence of interconnected chips. The presence of the elements involved in the superposition was confirmed by energy- dispersive X-ray (EDX) analysis. The results showed that the dielectric constant decreases with increasing the cobalt concentration, while the dielectric loss factor and AC conductivity increase.

Keywords: Dielectric properties, MgO, Sol-Gel, Nanoparticles, SEM, EDX

1. Introduction

Metal oxides such as magnesium oxide have attracted great interest due to their ease of preparation with different crystal shapes and sizes and being unstable in harsh processes but are safe for humans and animals [1]. The magnesium oxide (MgO) is an alkaline earth metal oxide that has a large band gap and structure of rock-salt of 4-5 volts. It has many applications for its ionic nature, surface quality, and high reactivity and these results in high efficiency in various reactions [2, 3]. There are many fields that use magnesium oxides, including sterilization, superconductor products, display panels, heat-resistant glass, fuel oil additives, toxic waste remediation, and insulation applications due to its low heat capacity and high melting point [4-7]. The minerals have the ability to form multiple oxides with various properties and ease of modification. These properties are through the doping process for use in multiple fields. Various crystal defects in the magnesium oxide structure give the deformation process a significant change in structural and electrical properties [6].This

research aims to study the effect of doping the nanostructured MgO compound with the transition metal cobalt ion on the structural and dielectric properties.

2. Experimental details

The sol-gel method of spontaneous combustion was used in preparing the compound ($Fe_{0.5}Co_xMg_{0.95-x}O$), and the four samples (X= 0.025, 0.05, 0.075, 0.1) were prepared, and in each preparation, the molar ratio of the fuel used was (citric acid), with the proportion of mineral salts at 1:1. The analytical grade metal nitrates, i.e., Mg $(NO_3)_2 \cdot 6H_2O$, $Fe(NO_3)_3 \cdot 9H_2O$ and $Co(NO_3)_2 \cdot 6H_2O$, were taken as the starting materials. The soul-gel spontaneous combustion method was used to prepare the compound. Metal nitrate and citric acid are dissolved separately in distilled water according to the molar ratios calculated for each sample. The nitrate solution is mixed with the acid solution in a suitable great heat-resistant flask, and the components are mixed by a magnetic mixer, and the acid function (pH) is adjusted until about (7) is reached, by adding ammonia to the solution in the form of drops. The ingredients were mixed for (30 minutes) to ensure the homogeneity of the solution and a good distribution of the ingredients at room temperature. The temperature is raised and fixed at (80 ^oC) for all proportions, and after a short period the gases start to rise and leave the reaction and the stirring will be continuous until reaching the gel form. After a period of half an hour, the jelly starts to burn to form a dry gel, which is grounded with an agate mortar. The resulting powder for each sample was placed in a container in the oven. For the purpose of calcination at a temperature of (600 ^oC) for two hours at an rising rate (10 deg/min), in order to get rid of the reaction residues that may still be stuck, such as water residues, and carbon dioxide residues arising from Combustion, and obtaining the required phase.

3. Results and discussion

3.1. XRD Phase Analysis

The results of the examination with X-ray diffraction technology of the compound $Fe_{0.5}Co_xMg_{0.95-x}O$, which are shown in Fig.1, showed that the prepared compound was of the cubic type for all of the samples (X= 0.025, 0.05, 0.075, 0.1) and the appearance of peaks of planes, (111), (200), (220),(311) and (222). When comparing the locations and intensities of the peaks with the JCPDS card for MgO numbered (45-0946) [8], we found that they are somewhat similar. Some additional peaks appeared in the XRD spectra for the secondary phases corresponding to Fe_2O_3 (JCPDS card No. 00-040-1139). Where we note that the intensity of the magnesium oxide peaks increases with increasing the concentration of cobalt. This result confirms that the crystallization ratio has increased due to the decrease in the width of the curve of the middle of the great peak (FWHM), as the increase in the height of the peaks is evidence of increasing crystallization and reducing crystalline defects by giving the material atoms potential energy to rearrange themselves in the lattice [9]. The lattice constant (a) with respect to the cubic structure is calculated according to the relationship (1) [10], where (hkl) is the Miller indices and d is the vertical distance between the planes of crystal.

$$\frac{1}{d^2} = \frac{h^2+k^2+l^2}{a^2} \quad \ldots\ldots (1)$$

The average crystal size (D) of samples was calculated using the (Formula Williamson-Hall) method according to the relationship [11] (2).

$$\beta \cos\theta = \frac{k\lambda}{D} + 4\varepsilon \sin\theta \quad \ldots.. (2)$$

Where K is the constant (0.94), β Full width at Half Maximum (FWHM) measured in radial units, θ Bragg angle , ε the strain, λ the wavelength of the X-rays incident upon the target = 1.5406 Å.

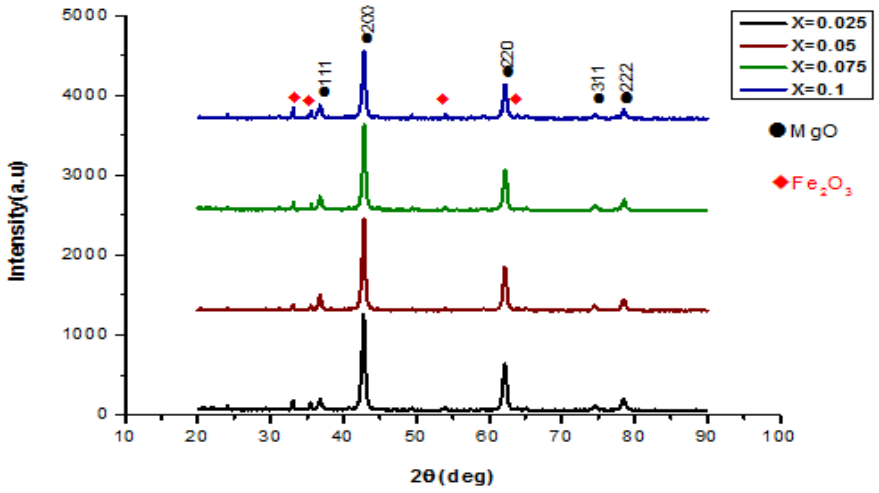

Fig.1. XRD patterns of $Fe_{0.5}Co_xMg_{0.95-x}O$.

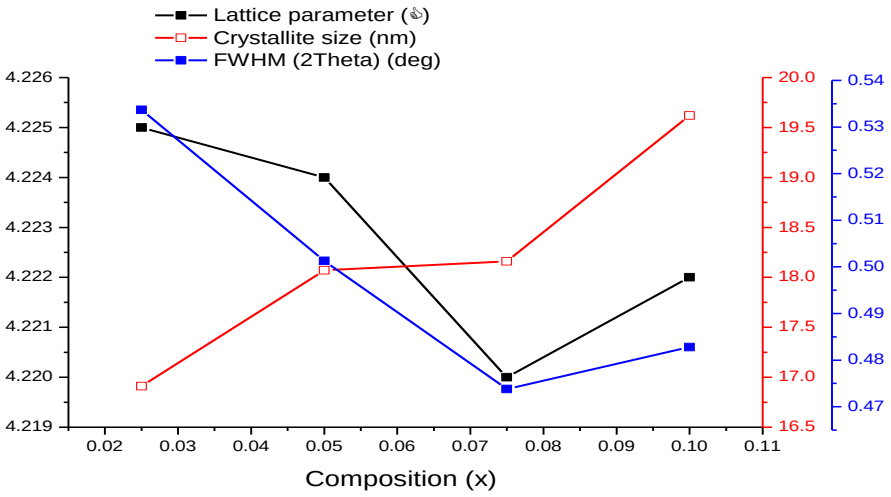

Fig.2. Lattice parameter of a $Fe_{0.5}Co_xMg_{0.95-x}O$, Crystallite size and FWHM with composition (x= 0.025, 0.05, 0.075, and 0.1).

The X-ray diffraction in Fig.2 showed a decrease in the lattice constant with an increase in the concentration of cobalt ions. This is a result of the gradual replacement of magnesium ions with a larger ionic radius (0.89Å) with cobalt ions with a small ion radius (0.58), which led to the deformation of the lattice and expansion [12-14]. As shown in Table.1, the full width value at half the maximum (FWHM) of the peaks decreased and the crystallite size of the samples increased with increasing x-values. It is noted that showed the full width value at half maximum (FWHM) of the peak (200) it decreased from 0.53370Å to 0.48280Å and the crystallite size increased from 16.91nm to 19.61nm with increasing cobalt concentration, which means that the surfactant increased the crystallite size [14].

Table 1: Lattice parameter, crystallite size and FWHM for peak (200).

Composition (x)	FWHM (200)	Lattice parameter a[Å]	Crystallite size [nm]
0.025	0.5337	4.225	16.91
0.05	0.5013	4.224	18.07
0.075	0.4738	4.220	18.16
0.1	0.4828	4.222	19.62

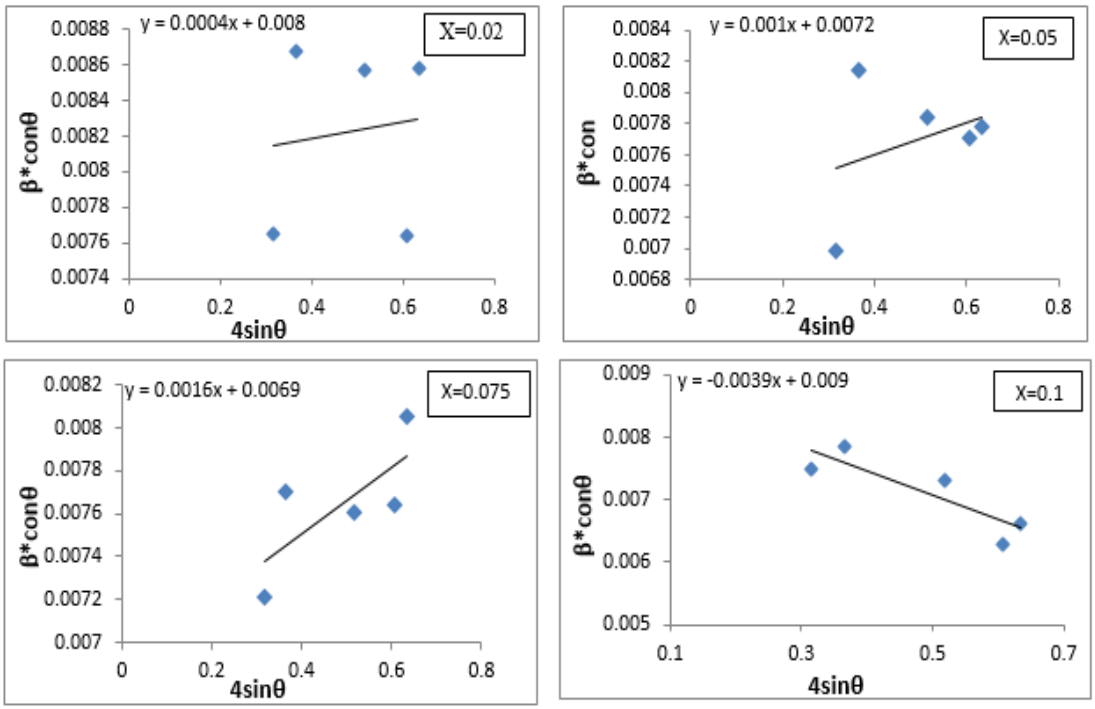

Fig.3. Hall–Williamson plots for samples $Fe_{0.5}Co_xMg_{0.95-x}O$ for (X= 0.025, 0.05, 0.075, 0.1).

3.2. SEM and EDX analysis

The SEM images in Fig. 4 show the formation of semi-spherical granules in addition to the presence of interconnected chips with no clear boundaries between them due to accumulation of nanoparticles and an increase in the randomness and porosity with increasing cobalt concentration. It was found that the average grain size of the compound ranged between (36.9-59.8 nm) with increasing cobalt concentration. Fig. 5 show the histogram of the particle size of $Fe_{0.5}Co_xMg_{0.95-x}O$ samples.

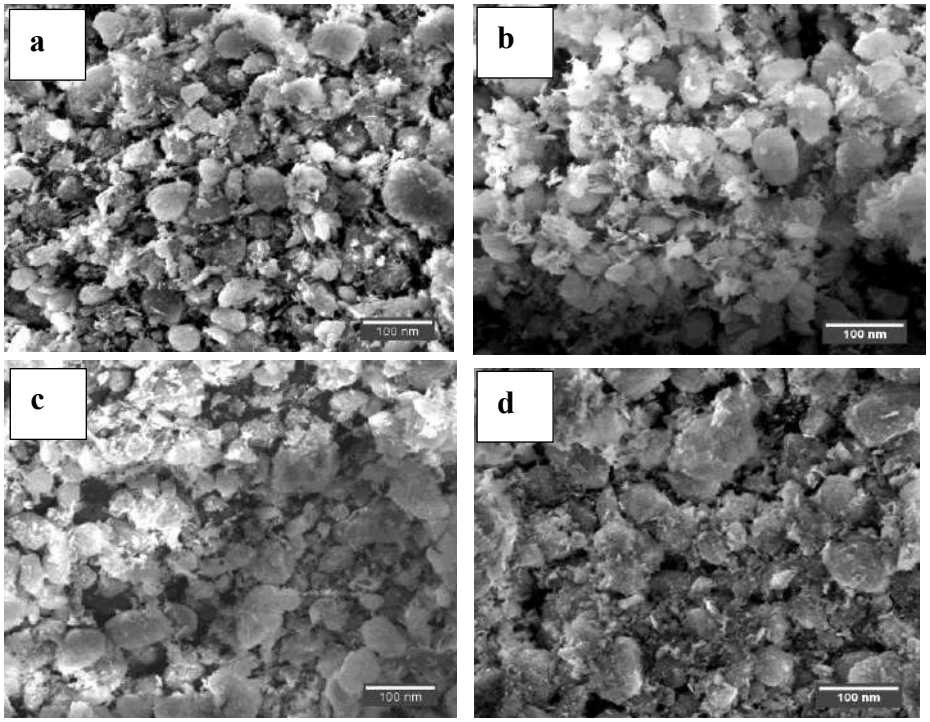

Fig.4.(a–d) SEM images of $F_{0.5}Co_xMg_{0.95}O$.

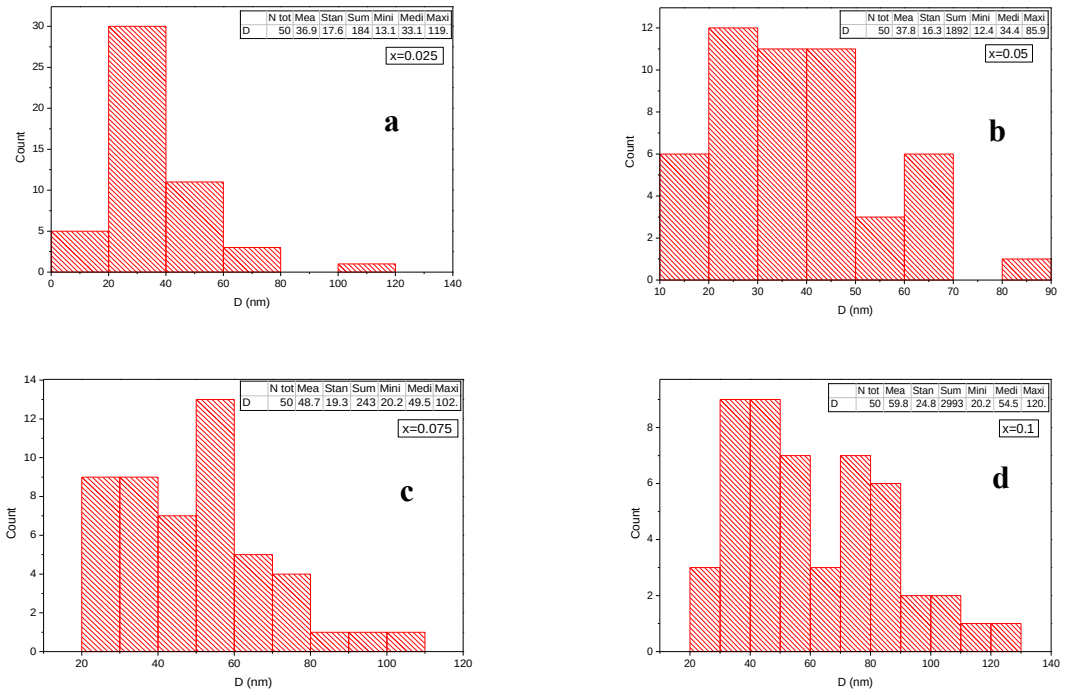

Fig.5. Histogram of the particle size of $Fe_{0.5}Co_xMg_{0.95}O$ samples.

The initial composition of $Fe_{0.5}Co_xMg_{0.95-x}O$ was observed in samples via energy dispersive spectroscopy. The diagrammatic consequence for EDX is appeared in Figure (6). It can be seen that

the predominant peaks concern magnesium, oxygen, iron, and cobalt, which appear the superimposed nanoparticles of these elements.

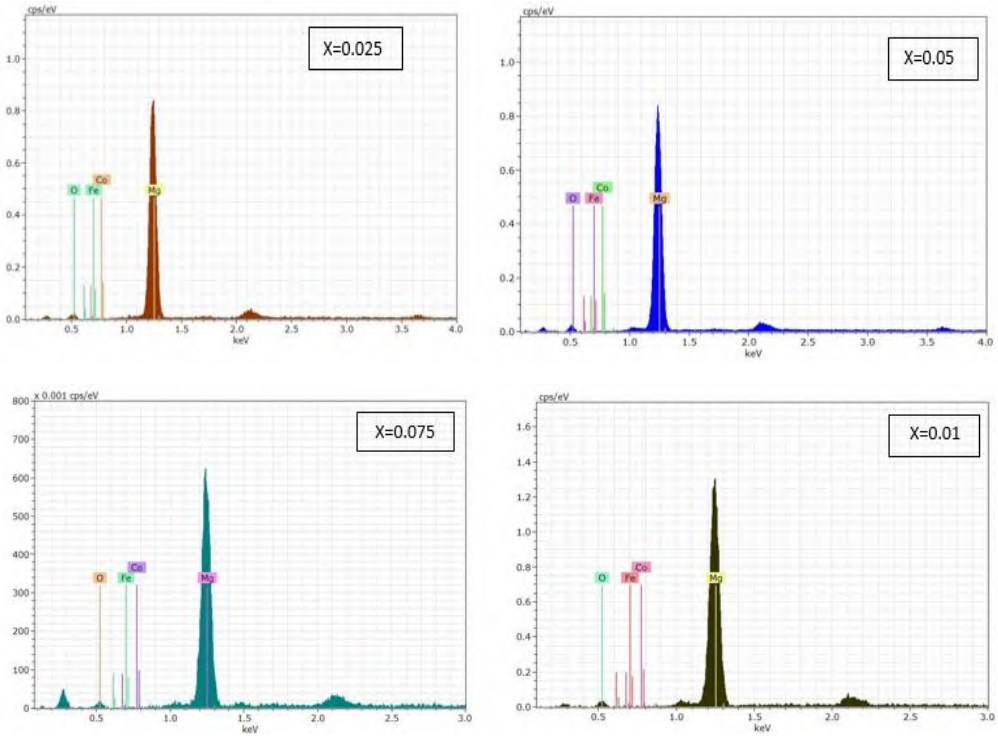

Fig. 6. EDX spectra of $Fe_{0.5}Co_xMg_{0.95}O$ (X= 0.025, 0.05, 0.075, 0.1).

3.3. Dielectric Properties

The dielectric properties of the composite samples $Fe_{0.5}Co_xMg_{0.95-x}O$ were studied as a function of the alternating electric field frequency within the range ($50H_Z$-$1MH_Z$) and at room temperature, which included dielectric constant, dielectric loss coefficient and alternating conduction.

Fig.7 shows the change of the dielectric constant with the electric field frequency applied for all ratios of cobalt addition to the compound $Fe_{0.5}Co_xMg_{0.95-x}O$. It can notice that the decrease of the dielectric constant with the increase of the frequency. It is because at low frequencies the dipoles in the dielectric have sufficient time to orient themselves completely in parallel to the applied electric field. When the frequency of the electric field increases, the dipoles lag behind in rotation and regularity with the electric field and this leads to a decrease in polarization and thus lower values of the dielectric constant [15]. That means the dielectric constant decreases with increasing the concentration of cobalt ions in the samples. Theoretically, the dielectric constant of the compound should be increased because the ion polarization of cobalt ions is greater than that of the magnesium ions, thus increasing the overall ionic polarization of the composite $Fe_{0.5}Co_xMg_{0.95-x}O$ with values of x [16]. There are two main reasons taken into consideration in the decrease of the dielectric constant. Replacement of cobalt ions with magnesium ions, which led to the lattice deformation and expansion, thus increasing the porosity [12], which in turn reduces the relative density. On the other hand, the cobalt content is very low and thus does not cause a rise in the constant of dielectric [17].

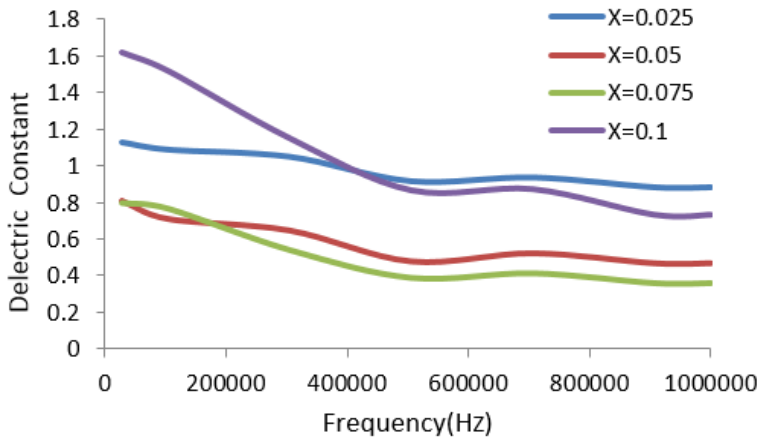

Fig.7.Variation of dielectric constant with the frequency of $Fe_{0.5}Co_xMg_{0.95}O$.

Fig.8 shows that the dielectric loss factor decreases with the frequency and there is a stable relationship between the emergence of dielectric and the conduction mechanism. There are several factors that can affect the dielectric loss factor such as the synthesis method, calcination temperature and formation. The variation of dielectric loss in the low frequency range can be explained by the Maxwell - Wagner model [15,18]. The greater amount of the dielectric loss at lower frequency is due to the jump among Mg^{+2}, Co^{+2}, and Fe^{+3} and the applied field monitors by the electrons. The electrons with increasing the frequency, are not able to follow the higher applied frequency that reduces the jump among Mg^{+2}, Co^{+2}, and Fe^{+3}. Thus, the loss of the applied field is minimal at the larger frequencies [19].

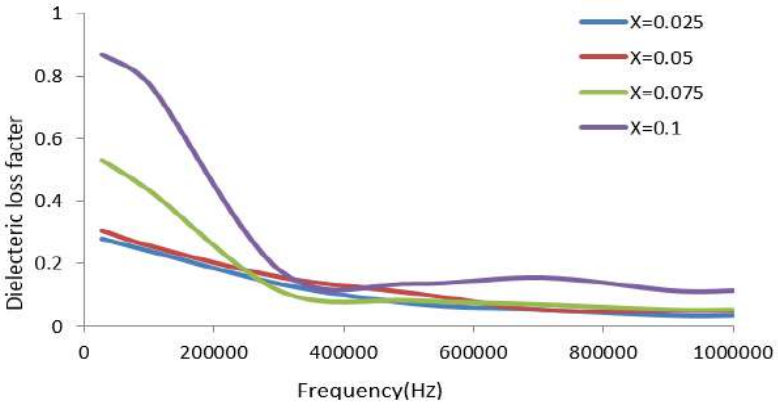

Fig.8.Variation of dielectric loss factor with frequency of $Fe_{0.5}Co_xMg_{0.95}O$.

Fig.9 shows a non-linear behaviour between AC conductivity (σ_{ac}) and frequency which shows that the amount of ac conductivity rises with frequency. Different conductivity operations, for instance tunnelling, jumping and free-range connection etc. participate in increasing the value of the alternating conductivity. It has been found that the adding of Co ions increases the conductivity of superposition [20].

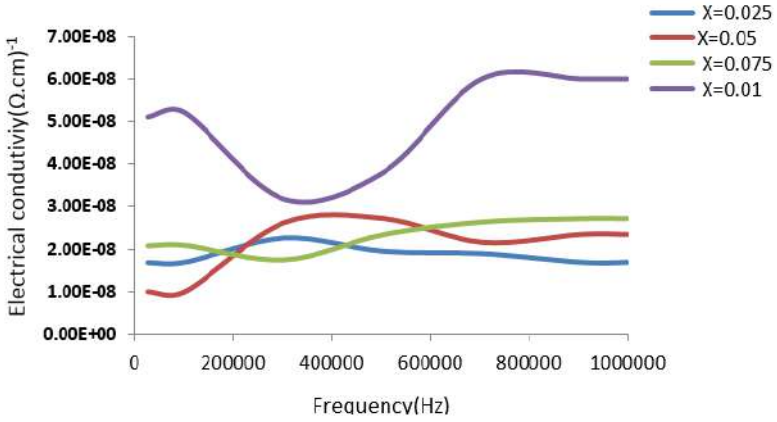

Fig.9.Variation of alternating connectivity with frequency of $Fe_{0.5}Co_xMg_{0.95}O$.

4. Conclusions

The structural and dielectric properties of $Fe_{0.5}Co_xMg_{0.95}O$ were studied. Where it was found that the lattice parameter decreases due to the small ionic diameter of the cobalt ions compared to the ionic radius. For iron ions and the ionic radius of magnesium ions, the crystal size increases with increasing cobalt ion concentration. The EDX results confirm the presence of elementary elements to form the compound. SEM images showed the formation of semi-spherical granules and an increase in randomness and porosity associated with an increase in the concentration of cobalt in the compound. It was noticed that the dielectric constant decreases with the increase in the ratio of cobalt ions, although the ionic polarization of cobalt ions is greater compared to the magnesium ions. The dielectric loss factor and the alternating conductivity increases with the increase in the cobalt ions concentration.

Investigation of Single-Phase Flow Characteristics in an Inline Pin-Fins Complex Geometry

Investigation of Single-Phase Flow Characteristics in an Inline Pin-Fins Complex Geometry

R. Shakir[1]

[1]Petroleum and gas engineering department, college of engineering, university of Thi-Qar, Iraq.

E-mail: shraed904@gmail.com

Abstract. In this guess investigation of concerns R113 heat transfer of pressure drop flow in single-phase flow in inline on the square shape of micro- channel of pin-fins own a (5x5 mm2) cross- area segment section via of (5 mm) heightly. Therefore, the inline square micro- channel of pin-fins complex geometry additionally owning (25) numbers of the pin-fins, total pin-fins channel dimension (50 mm x 50 mm).Subsequently.The liquid has (25 °C) inlet temperature for the same inlet temperature six mass flow rates were applied, ranging from (0.0025 - 0.01 kg/sec), and heat apply ranged from (40 -200 Watts).Guess single-phase heat transfer coefficients, guess liquid temperatures and guess wall temperatures were reported in this investigation

Keywords: pin-fins, heat transfer, single-phase flow, prediction setup.

1. Introduction

Cooling of electronic and electrical devices is reuired to ensure their accuracy and optimum working conditions. The pin fins complex geometry provides a higher heat transfer area per unit volume and low thermal laziness than straight channel fins. The vitality created in the downstream of the fins supplies for mixing between liquids and increases heat transfer. The thermal properties and hydraulic properties of the pin-fins heat sinks are dependent on several important parameters such as the porosity, pin fin shape, an arrangement of fins namely: in-line pin fins or staggered pin fins, short fins and full-length fins, fin length, and the guidance of the fin with attaching to the liquid flow direction [1–8]. Therefore, the pin-fins complex genome is still a topic of active research by many investigators are working under this area investigation. At last, the aim of this study is to find out the performance of the best type of mini-scale complex geometry.

2. Theory and Formula

The guess heat transfer properties for flow is define based on the liquid and wall temperatures conforming to the system pressure as indicate to liquid temperature. The analysis models of guess data are classified in the according steps.

$$F_{sp} = \left((q_{th}/A_{th})/\left(T_w - T_f\right)\right) \quad (1)$$

In where (qth) is that the position of heat flux, (Fsp) symbolize to that of single-phase coefficient for heat-transfer guess; (Tf) symbolize to liquid temperature ;(Tw) the local wall temperature and amend

the bottom of a micro pin fins square heat sink heat sink, amend (Ath=W x L). The projection on the test segment contains the plate sort heaters. While insulated had used for rear face on the test segment; within bottom of test section there's an electrical heater device and top of test section there is an R113 working liquid. Figure 1. It is shown the design can simply create a uniform heat flux distribution at the solid–liquid interface. Some preparation wanted the heat conductivity via the wall to be introduced into the analysis. The variance in temperature crosses. The flow has not been revealed to also be needful. The controlling conduction wall influence has so imagined being two-dimensional array; first-dimension perpendicular to the R113 liquid working flow and second the parallel dimension there to R113 liquid working,so heat conduction equation is [9].

$$\delta^2 \mathrm{T}/\delta y^2 + \delta^2 \mathrm{T}/\delta z^2 = 0 \qquad (2)$$

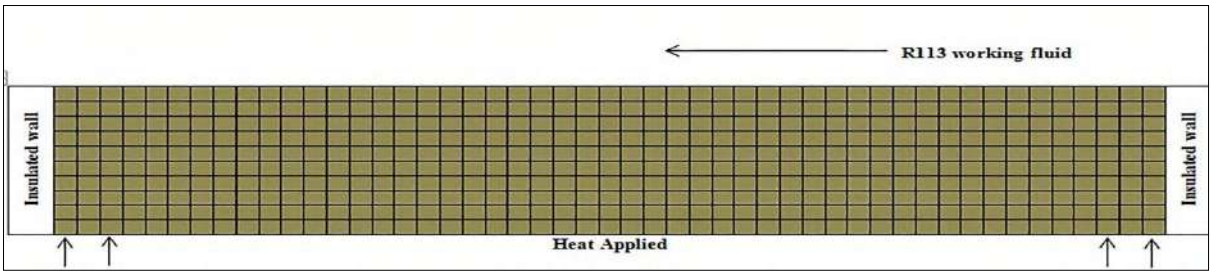

Figure 1. Aluminum Test Piece Wall Conduction.

Which (y-axis) represents in present axis.The temperature in is perpendicular to the flow and (T) in an aluminium wall".Conduction of heat equation (2) had got via the segmentation of the cells square area.The cells square have (one mm); consequently, (one mm) cells were utilized from the figure one. For each cell, an energy equilibrium gained from Ref.[9]

$$\mathrm{T_{i,j}} = \delta \mathrm{y}^2\left(\mathrm{T_{i+1,j}} + \mathrm{T_{i-1,j}}\right) + \delta z^2\left(\mathrm{T_{i,j+1}} + \mathrm{T_{i,j\_1}}\right)/2\ (\delta \mathrm{y}^2 + \delta \mathrm{z}^2) \qquad (3)$$

"Where (δz) and (δy) have the dimensions of the cell.Equation (3) shows variance of needed on perform.Therefore, The conditions of the borders "iteratively until the temperature in each cell was the same as the cell, it was solved.Former guessed to a guess of (0.001) error ".Consequently, the positioning wall temperature was gained via averaging of data from the relevant thermocouples, to gain (Tth) " Where it was then corrected from the plate surface for depth,(Lth); " perfect the equation of one-dimensional into heat conduction

$$T_w = T_{th} - (q_{th} L_{th}/K_A) \qquad (4)$$

"In which (KA) aluminium thermal conductivity; " The heat transfer coefficient of the position was gained via detaching the flow filed into cells while a typical two-dimensional unit cells at the location of a thermo-couple situated inside the test piece. The fluid temperature for the pin-fins test piece for a fluid with a specific heat capacity of (Cp) was got by equation below":-

$$T_f = T_{in} + \left(q_{th} WZ/M_f C_p\right) \qquad (5)$$

Where (Mf) is the rate of mass flow of R113 working liquid was equipped," The width of the test piece is the (W). The guess single -phase of heat transfer coefficient can be evaluated via useing following equation":

$$q_{th} A_{cell} = h_{esp}(T_w - T_l)\left[(A_{cell} - A_c) + \eta_{fin} A_{fin}\right] \qquad (6)$$

Equation (6) is gained a simple energy balance is applied to a unit cell which contains a single micro pin-fins. In addition, the surrounding base surface as presented. The left of a side equation (6) .The heat input to the unit cell is represented, and the heat removal from the unit cell by the unit cell is

represented on the right-hand side of R113 single-phase testes. In equation (6). (A_{cell}) Indicates the base region of the unit cell.

$$A_{cell} = S_l S_t \quad (7)$$

In which
S_l= The distance from the central cell to another centre cell in a length direction.
S_t= The distance from the central cell to another centre cell in a width direction.
A_{fin} = The moistened surface region of the single pin-fins.

$$A_{fin} = P_{fin} H_{fin} \quad (8)$$

And η_{fin} represents the fin efficiency,

$$\eta_{fin} = tanh(m_{fin} H_{fin}) / m_{fin} H_{fin} \quad (9)$$

In where mfin is the fin parameter,

$$m_{fin} = \sqrt{h_{esp} P_{fin} / K_A A_c} \quad (10)$$

Where A_c is the cross-sectional area of a single micro-pin-fins,

$$A_c = W_{fin} L_{fin} \quad (11)$$

And P_{fin} is the cross-section perimeter of a single micro-pin-fins,

$$P_{fin} = 2(W_{fin} + L_{fin}) \quad (12)$$

In where [W_{fin}] is pin-fin width in (mm);[L_{fin}] is the pin-fins length in (mm) and [H_{fin}] is pin-fins height in (mm).
The guess wall temperature T_{wp} distribution along the inline pin-fins channel is found.

$$T_{wp} = T_{in} + q_{th} WZ / M_l C_p + A_{cell} q_{th} / \left[(A_{cell} - A_c) + \eta_{fin} A_{fin} \right] h_{esp} \quad (13)$$

Where prandtls number based on the hydraulic diameter of the channel as follows:

$$P_r = \frac{C_p \, \mu_f}{k_f} \quad (14)$$

The Reynolds number can be found by-

$$R_e = \rho_f V D_h / \mu_f \quad (15)$$

In where the hydraulic diameter of the channel in the presence of heat transfer analysis, seen by

$$D_h = \frac{4 \, . A_c}{P_{fin}} \quad (16)$$

Since only three sides of the in line micro pin-fins were heated in the investigation work, the approach utilized in Lee et al [10].Is adopted here to guess the Nusselt number in single-phase flow based on results in the literatures that apply it all four sides of the in line micro pin-fins being heated can find by Ref.[9]

$$NU_{x,3} = NU_{x,4} \frac{NU_{fd,3}}{NU_{fd,4}} \quad (17)$$

In where $N_{ux,4}$, $N_{ufd,3}$, and $N_{ufd,4}$, were found to be gained respectively," For the geometry and boundary conditions considered.Friction factor can be calculated via Ref.[11].

$$f_{laminar} R_e = 24(1 - 1.3553 + 1.946\beta^2 - 1.7012\beta^3 + 0.95641\beta^4 - 0.2537\beta^5) \quad (18)$$

The pressure drop can be got from according to the method of Liu and Garimella. In which (β) is the aspect ratio of the square channel, and laminar is the Fanning friction factor Ref.[12].

$$\Delta P = 2\, f_{laminar} R_e\, \rho_l V^2 \frac{L}{D_h} \qquad (19)$$

3. Prediction Setup

The rig consists of three prime elements, the flow loop system, and the test section of aluminum and the test piece of aluminum inline pin-fins complex geometry.

3.1. FLOW LOOP

Suppose the rig has a projects for a new technique for Figure 2, the flow loop system is seen illustrated in below. Before running the single-phase test concatenations, the R113 working liquid was degassed for almost two hours under strong heat tests to force any dissolved gases to get away from the system to the atmosphere through strong heat test concatenations.The vent valve on top of the pr-eheater was intermittently opened wthin this interval to permit dissolved gas to run away to the atmosphere.As well as , the test pressure was set to close to atmospheric pressure.Fluid R113 had dragged by an accumulator unit via pump after degassing R113 working liquid, so no gas or air bubble appeared to come out of the liquid within the test piece before a single-phase test concatenations.Therefore, valves within the by-pass and major streaks permit the wanted adjusting the rate of mass flow.Thus, a coarse filter was mainly employed to block large debris.Within testing the finer filter was employed.Thus, guess tests have been performed via adjusting the optimal R113 mass rate of flow and inlet temperature (M_f and T_{in}). Within testing, a coarse filter had been employed to block large debris.The mass flow had been balanced via the flow meter, thus, the by-pass valve, and balanced via the dominant valve prior to the complex geometry of the inline pin-fins complex geometry .With consideration to the mass flow of the test, the controller varied the necessary heat applied to the R113 liquid flow that passed the pre-heater to produce the suitable inlet temperature to the complex geometry of inline pin-fins in the aluminum house. A pre-heater had been joined of the system controller unit. A test section heater had been simultaneously set to the needful heat applied to the test piece of aluminum.The R113 working the flow loop was circulated with liquid to system until the needful Steady-state conditions were gained.This process took about three hours for steady-state conditions approximatly. It was needful to force the temperature of the outlet heater and the temperature of the aluminum housing to be steady as well. These cases were roughly 40-85 minutes in length.The method iterated during the single-phase tests to maintain the system pressure similar to the ambient pressure, thereafter determined readings had been completed prior then heat applied had re-set successive needed value.

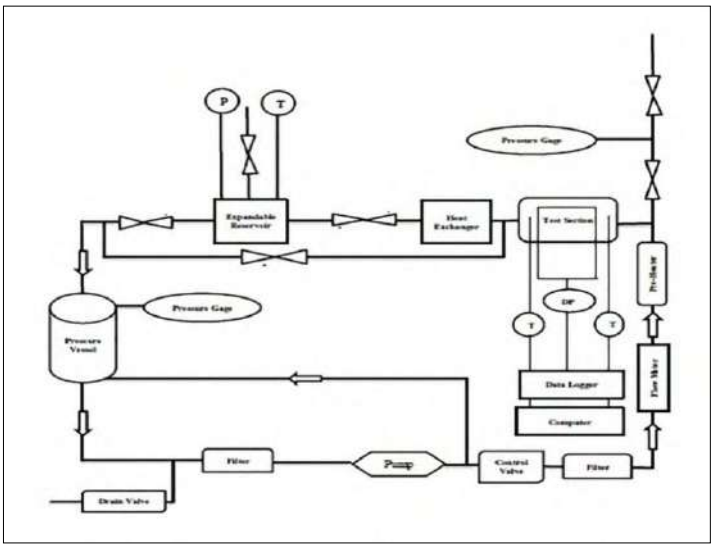

Figure 2. The Flow Loop[9].

3.2. ALUMINUM TEST SECTION

Figures (3 and 4) of the aluminum test segment utilized in this inquiry are presented in the procedures.The aluminum test section contains three sections, are called, an aluminum housing, The top-cover of the aluminum,Therefore, an aluminum of inline pin-fins complex geometry.If the aluminum top housing, the aluminum bottom housing, thus a base are all created of aluminum, aluminum housing is utilized.The top housing contains the complicated geometry of the aluminum of inline pin-fins complex geometry. It is the inlet plenum and outlet plenum, a pressure port also temperature port of sit a related sensors.Two pressure ports exist, one at the plenum inlet and the other at the plenum outlet.

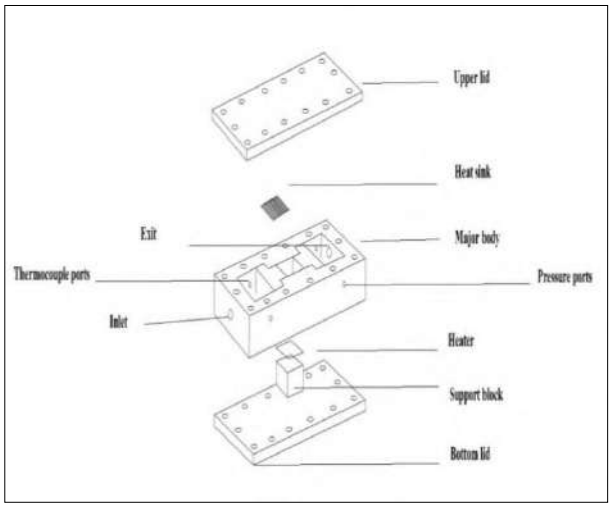

Figure 3. TesHousing [9]

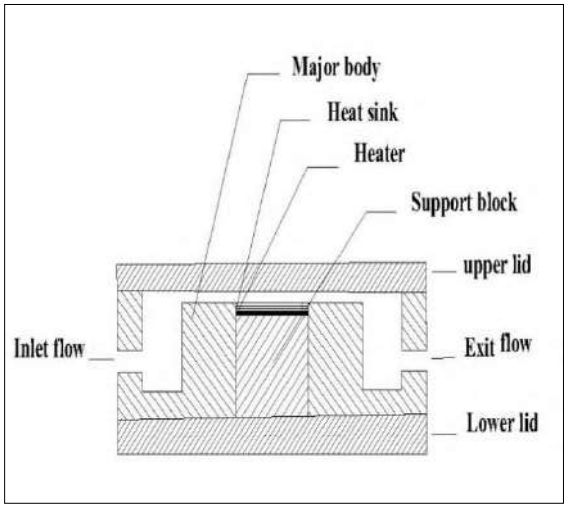

Figure 4. Test Section[9]

3.3. ALUMINUM TEST PIECE

Figure 5 presents the aluminum test piece of the aluminum of inline pin-fins complex geometry, all details have been gained from this figure; there are consequently six thermocouple ports, each one into plenum of inlet and a plenum of outlet and four below the aluminum of inline pin-fins complex

geometry surface.Thermocouples are utilized to measure the temperature of inlet location, the temperature of outlet location, and wall temperatures .The wall temperature of the thermocouples had a probe diameter of one mm and was force-fitted into two holes from the inlet location and two holes from the outlet location, all drilled eight mm below the inline pin-fins complex geometry surface and drilled twenty mm at the inlet and outlet ends of the test piece.Four sheathed k-type thermocouple produce these holes so that thermocouples had been measured in an extremely the bath of water then had accurate (±0 1.25 ºC) to roughly. On the surface of the top housing, a groove is cut out to the line. The aluminum inline pin-fins complex geometry have a height of ten mm and a footprint fifty mm by fifty mm.

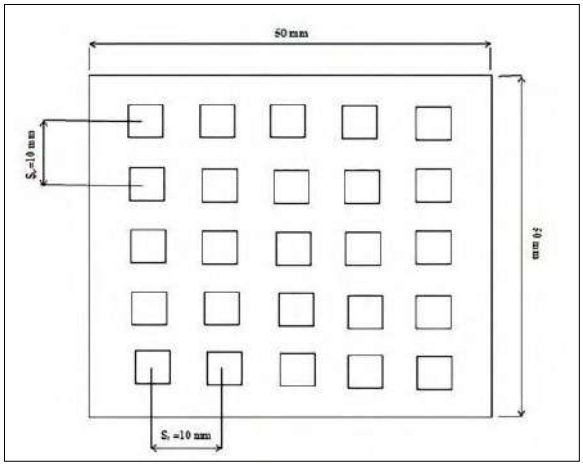

Figure 5. Pin-fins channels aluminum test piece

4. Results and Discussion

In Figure.6.The guess heat-transfer coefficients of single -phase are presented to the mass fluxes range.subsequently, at the inlet and outlet locations of the heat-transfer coefficients pin-fins complex geometry have one region ,It were laminar developing flows that mean the all guess tests are laminar developing flows , laminar developing regions are seen to grow with growing mass flux , with the inlet consequences significantly higher than the outlet consequences.Wall conduction influences are importantly affecting the consequences. The developing method from equation (17) is also included, consequently, power relationships have been gained that between for both inlet and outlet consequences for all guess tests.

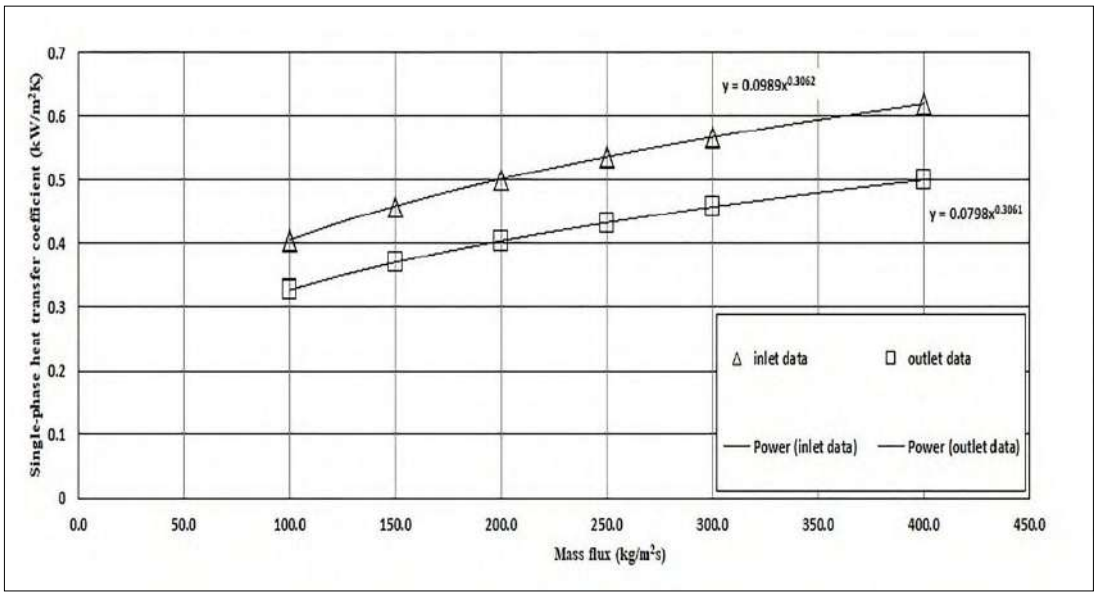

Figure 6. Single-phase heat transfer coefficient versus channel mass flux.

The guessed pressure drop between into inlet of plenum and outlet of plenum poitions to illustrate that the pressure drop are happened because of gain the flow in the pin fins complex geometry also the inlet losses and exit losses. In the pressure-drop consequences had presented in Figure.7, the inlet loss and exit loss positions are gained from the guess values according to the correlation of Liu and Garimella as debated above. It can be shown from Figure.7. Appears pressure drop increase powerly with increasing a channel mass fluxes.Thus , the inlet pressure drop consequences slightly bigger than outlet pressure drop consequences due to get that the pressure drop consequences depend on single-phase heat transfer coefficient and liquid characteristics .consequently, power relationships have been gained between for both inlet and outlet consequences . At last, the guess consequences are shown to be in a best agreement with the other guessing,theoretical and experimental correlations.

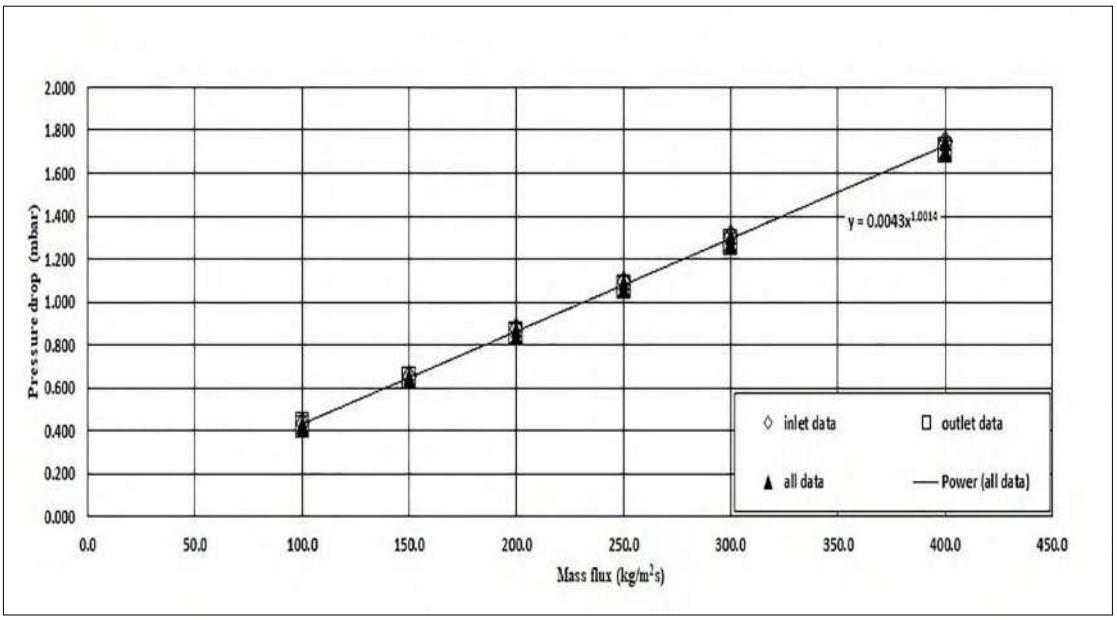

Figure 7. Pressure drop versus channel mass flux.

In Figure 8.The consequences of the correlation processed are compendium.The values heat-transfer coefficients of the single phase found that each channel contained one region, laminar developing flows which the heat-transfer coefficients should be gained by equation below:-

$$N_U = \tau(R_e P_r D_h/L)^{\lambda} \quad (20)$$

The processing set of analyze to uniform heat flux was proposed with, (q_{th}) this permitted the positions of coefficients of inlet and outlet heat transfer to gain from equation (6) to each heat flux and mass flux condition guessed tests. From another hand, we could be computed the heat-transfer coefficients were utilized in a least-squares operation to gain values of (τ and λ) in equation (20). This heat-transfer coefficient had wanted to wall conduction type and equation (4) had utilized to gain the R113 liquid temperature where for these guesses are the heat-transfer guessed temperature. A permitted the heat flux distribution to be got and thus an update to the inlet heat transfer coefficient and outlet heat transfer coefficient. The proceedings were duplicated unto the (τ) and (λ) are rationally steady.The iterative data guess operation opitomized in Figure.8, is gain the guess heat transfer correlation coefficients in Equation (20) ,(τ , as 1.407) and the index (λ , as 0.306). In end these consequences see that there is new correlation between guess single-phase heat transfer coefficients with hydraulic diameter, Reynolds number,Prandtl number and the distance from inlet aluminum pin-fins complex geometery.

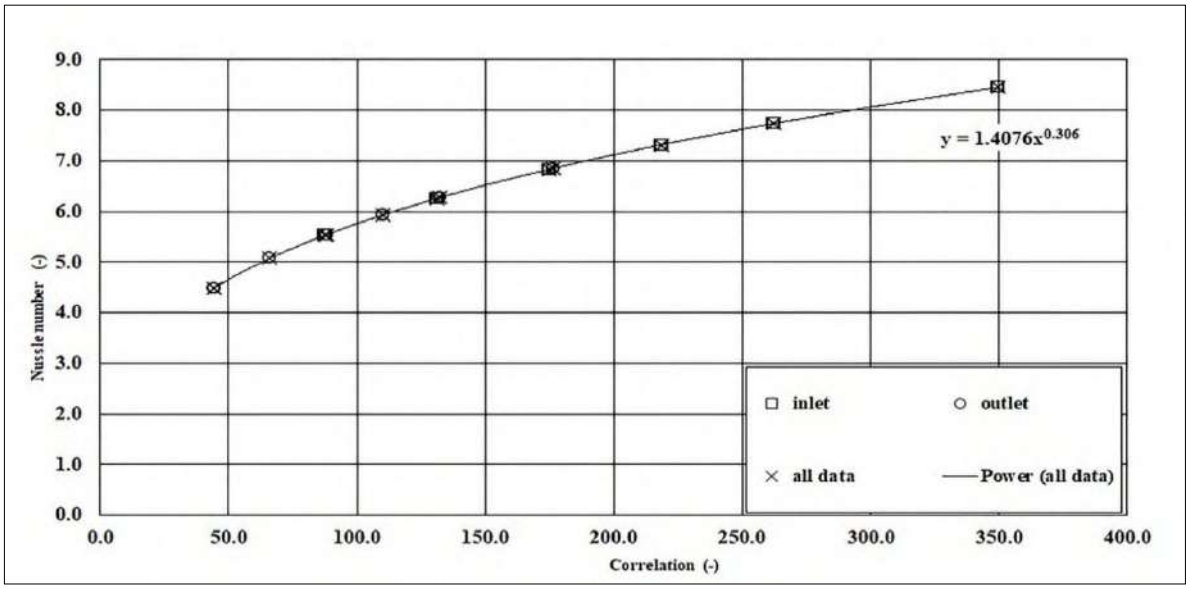

Figure 8. Nussle number versus correlation

5. Conclusions

This is an important study to get the heat transfer coefficient in single tests, so with the article results from effects, other implications were broadly in the direction. It is inspiring to remember that there are no major variations in each other's consequences. The variations of predicted on the flow single-phase of the dielectric fluid R-113 in a complex geometry was periodically studied. Special conceived correlation planning was developed that supplies R-113 fluid to the flow loop while at the same time, providing control of the mass flow rate and heat applied in the test section. As well, Degassing the R-113 fluid was discovered to have a strong effect on both the heat transfer and the pressure drop measured should be created before any tests. The following conclusions can be taken from this study:

The guess tests have one region laminar developing flows. The R113 liquid properties were gained by guess R113 liquid temperature. The maximum R113 liquid temperature during the test series was (32.80 ºC). In the laminar developing region, the inlet data consequences bigger than outlet data

consequences for test series. Because of aluminum test piece walls are deep insulated. Adiabatic conditions were proposed. High liquid temperature is gained with the low mass flow rate during the test series.

The effect of heat treatment on structure property of (Bentonite - Alumina - Silica) Ceramic

The effect of heat treatment on structure property of (Bentonite - Alumina - Silica) Ceramic

Athraa Najm Abdullah[1], Shatha Hashem Mahdi[1]

[1]Department of Physics, College of Education for Pure Science (Ibn-AL-Haitham), University of Baghdad, Iraq.

E-mail: azraa.najm1104a@ihcoedu.uobaghdad.edu.iq

Abstract. In this work, a ceramic model has obtained from Iraqi bentonite as a base material with limited additions of alumina and silica. The selected material can bear temperatures higher than the bearing temperature of bentonite as it achieved tolerance temperatures (1300 ºC) based on X-ray diffraction patterns. It was found that the addition of alumina and silica led to the occurrence of basic phases such as mullite, quartz, cordierite and feldspar in percentages that depended on the percentage of addition in the mixture and the firing temperature, which was (1000-1300) ºC.

Keywords: Alumina, Silica, Ceramic, Cordierite, heat treatment**.**

1. Introduction

Ceramic material is defined as the material made partially or completely from clays formed and burned to a certain degree in order to reach a solid product. Ceramic materials include all inorganic materials except for alloys and metals. Ceramic materials are generally classified as Traditional Ceramic and Advanced or New ceramic (1). The word clay is used to denote a rock with specific properties. The size meaning of clay is believed by that size consisting of very small grains, despite the different measures that determine the size of the upper limit of the clay particles. (2,3) Bentonite is a clay with a high degree of plasticity and the primary composition of the mineral is Montmorillonite. Bentonite derived from volcanic ash with three-layer mineral clays is (Montmorillonite. $A1_2O_3$.5 SiO_2.7 H_2O) has a fast-drying property that leads to shrinkage of the ceramic body, as well as due to the presence of a high percentage of alkaline content in the bentonite clay, which leads to its melting at a degree less than (1300ºC) and therefore it is not used in thermal conditions at this temperature [4, 5]. The aim of the research is to treat bentonite clays with thermal ceramic materials in a specific ratio at different temperatures. In addition to study the phase transitions of bentonite clays.

2. Method and Materials

Use bentonite clay (the yellowish zone), the chemical analysis of this raw material is shown in the table below. Chemical analysis of the raw material tests according to the Geological Survey Company.

Analysis of bentonite clay (yellowness zone).	
SiO_2%	50.8
Fe_2O_3%	5.62
Al_2O_3%	15.93
TiO_2%	5.69
CaO%	3.06
MgO%	4.5
L.O.I%	10. 72

The alumina and silica prepared by the Swiss company Fluka were used with purity (99.99%) and granular size (10 m). The samples were prepared by sifting the bentonite using a Sieve Mesh No: 500 sieves to obtain a granular size less than (30 µm). After that, the weight ratios that form the mixture of the ceramic material were calculated. After setting the weight ratios of the raw materials, the materials were mixed, where the pH value of the distilled water was set using litmus paper, where pH = (6), and the binder (PVA) was placed in a weight ratio of 1% per 100ml of distilled water and using magnetic stirrer to be left for half an hour at a temperature of (80 ºC), then we obtain a colloidal solution free of any sediment. After obtaining a colloidal solution free of any sediment, concentrated HCl acid was added by one drop to the mixture to obtain a solution of (pH = 3), after which the alumina was added in proportion 25% and silica by 10% and leave it to mix for an hour, after which bentonite was added by 65% and the mixing process was continued from (6h) to obtain the best possible homogeneity of the mixtures after obtaining a thick mixture. Dry the dense mixture in a laboratory dryer (Oven) at a temperature (100ºC) to get rid of the aqueous solution, then the crumbling process was carried out using a hand mortar (Mortar and Basel) to obtain the required base mixture The samples were formed by semi-dry pressing method, where they were pressed with a hydraulic press using a mold of stainless steel with a diameter (2.5cm) Compression of (5ton / cm2), compression time (60sec), and (5) mix samples were formed. Then the heat treatment of samples was carried out using a Carbolite type electric furnace at the required temperature degrees (1000, 1100, 1200, 1250, 1300) ºC at a time of rising temperature of (5ºC / min) for two hours. The mineral composition was measured using the X-ray diffraction technique and using SIEMENS X-RAY DIFFRACTION UNIT MODEL.

3. Results and Discussion

A set of mineral changes took place on the raw materials used in the preparation of ceramics as a result of demolition reactions, structural reactions, and reconfiguring new phases. The first stage included the occurrence of some demolition reactions that lead to the evaporation of porous and surface water and the loss of crystalline water that causes the collapse of the crystalline structure of clay minerals and the decomposition of limestone At a temperature of (700) ºC and after that the structural reactions take place, when the raw materials interact with each other at temperatures [(700-1000), (700-1100), (700-1200), (700-1250) and ((700-1300)] ºC form some new metallic phases. And the mineral analysis of the components of bentonite clay was treated with a temperature of (1000.1100.1200) ºC. Mineral analysis was also performed for ceramic objects produced from bentonite clays at temperatures of (1250-1300) ºC, noting that bentonite is not used as a base material in the production of ceramic bodies, especially at sintering temperature (> 1200) ºC due to its containment of molten oxides. After analyzing the X-ray diffraction patterns shown in Figures (1) to (5) and weighing them with the values of (2Ɵ) for each of the resulting phases with those studies referred to by the ASTM files and calculating the concentrations of those phases [6].

Where these diagrams indicate that the ceramic samples prepared from bentonite clay as a base material, alumina (25% - Al2O3) and silica 10%-SiO2) have undergone some mineral changes, the most important of which is the disappearance of clay minerals because they do not tolerate high temperatures and water loss.Crystallization, which led to the collapse of its crystal structure.In addition, the calcareous materials are completely decomposed after their consumption to form new mineral phases, the most important of which are mullite with its symbol M, feldspar its symbol F, Cordierite (C) and a small percentage of quartz (Q).

The resulting phases of the bentonite clay model with a temperature of (1000) ºC are mullite (53.44484) %, feldspar (43.60812)%, and quartz (2.947033)%. As for the same model treated with a temperature of (1100) ºC, the resulting phases were mullite (48.66131)%, feldspar (41.49933)%, Cordierite (7.362784)%, and quartz (2.476573)%, and when treated with 3a temperature of (1200) ºC, the phase of Cordierite (7.612457%) and mullite 56.12457)%, feldspar (33.91003)% and quartz (2.352941)%, and the bentonite slurry was permanently converted into mullite (56.0794)%, feldspar (32.63027)%, as well as Cordierite (9.119107)% and quartz (2.171216)%, when treated at a temperature of 1250 ºC . As for the modulated model within the thermal range (1300) ºC, the resulting phases were mullites (49.77893)%, feldspar (41.06632)%, Cordierite (7.594278)%, and quartz (1.560468)%, by observing the X-ray diffraction patterns of the treated models within the temperature range (1000-1300) ºC where new phases appeared (Cordierite) in addition to mullite, feldspar and quartz, as these resulting phases have good insulating properties.

4. Conclusions

In this paper, a ceramic model was obtained from Iraqi bentonite with limited additions of alumina and silica that bear a temperature higher than the bearing temperature of Iraqi bentonite, as it achieved a severe temperature of 1300 ºC. The addition of alumina and silica led to the occurrence of basic phases, which are mullite, feldspar and quartz, in addition to Cordierite. Adoption of these thermally treated ceramics at (1000, 1100, 1200, 1250, 1300) ºC and a maturation time of (2hr), thus this mixture is considered successful.

Abstract. In the current study, an implicit algorithm has been applied to solve the nonlinear equation of a single diode solar cell using several iterations with an initial value of $x_0 = 1$. The proposed algorithm is achieved with the different values of load resistance. The equation based on equivalent circuit of a solar cell and all the determinations are implemented at ambient temperature using MATLAB program. The obtained results of this new method are given, and the absolute errors are investigated.

Keywords: Implicit method; single diode model; parameters; iterations; load resistance.

1. Introduction

Numerical analysis is a science of approximation where numerical methods are used to solve complex and unsolvable problems by analytical methods. In numerical analysis, all aspects of the existing problem are studied numerically, using theoretical development, understanding of numerical methods, and attempting to implement them in the form of computer programs. These programs are characterized by a high level of confidence and effectiveness. Common interests and perspectives among them, which include mathematical methods of numerical analysis is based on the principle of creating, analyzing, and implementing a number of algorithms to arrive at digital solutions to mathematical problems that are built on a range of constant variations and fluctuations, such as quantitative analysis, or numerical methods [1-8]. Photovoltaic have been used in space for a long time in 1958, when Van Gard was launched, with 6 photovoltaic cells on its surface. While other batteries stopped working shortly after the ship was launched, since then, solar photovoltaic cells have been widely used in space and their use has helped to increase the length of spaceflight. For spaceships and high reliability relatively high yield. The main idea is to reproduction electrical energy by means of photovoltaic cells, which form solar cells. Several kinds of solar cells are synthesized based on the material used and fabrication technique such as silicon, organic and inorganic solar cells [9-55]. This study proposes a method for estimating parameters in single diode model of a solar cell equation based on implicit algorithm (IM) and explains the performance of this estimation method. It is organized as follows: Section two characterizing the analytical model of a single-diode design of the solar cell; Section three establishing the root finding Implicit algorithm (IM); Section four results and discussion; Section five conclusions of the acquired results.

2. Characteristics of Single-Diode Solar Cells Equation

A photo voltaic cell (equivalent circuit) is shown in Figure 1.

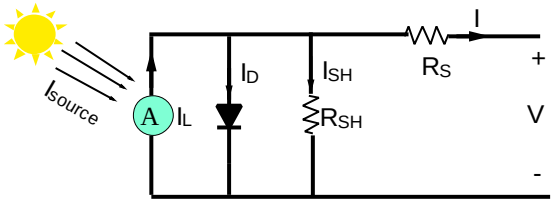

Figure 1. Single-diode electrical equivalent circuit model of a solar cell.

By applying Kiechoff's current law for the circuit, the equation of this equivalent circuit is given by

$$I = I_{ph} - I_D \tag{1}$$

$$I_D = I_0\left(e^{\frac{-V_{pv}}{nV_T}} - 1\right) \tag{2}$$

$$I = I_{ph} - I_0\left(e^{\frac{-V_{pv}}{mV_T}} - 1\right) \tag{3}$$

where:
I_{ph} is the photocurrent (A); I_0 is reverse saturation current of the diode (A); I and V_{pv} are the delivered current and voltage, respectively (V); $V_T = \frac{kT}{q} = 0.0259\,V$ is thermic voltage $= 27.5 \cong 26\,mV$ at ($T =$ 25 °C Air-Mass = 1.5); m is the recombination factor closeness to an ideal diode $(1 < m < 2)$, k is Boltzmann constant$= 1.38 \times 10^{-23} J/K$; T is $p-n$ junction temperature (K); q is the electron charge$= 1.6 \times 10^{-19}\,C$.

$$I_{ph} = I_{source} \tag{4}$$

$$I_D = I_s * \left(e^{\frac{V_D}{nV_T}} - 1\right) \tag{5}$$

Merge Eq. 4 in Eq. 5 we get

$$(I_{source}) - 10^{-12}\left(e^{\frac{-V}{1.2*0.026}} - 1\right) = \frac{V}{R} \tag{6}$$

where: I_s reverse saturation current$= 10^{-12}A$. In parallel, $V_D = V_{pv} = V$
According to Eq. 6 one can calculate V of the cell numerically based on the first derivative of this equation.

3. Implicit Method (IM)

The following algorithm suggestion for solving Eq. 5 by using NRM
Initial approximate solution $x_0 = 1$, tolerance ε,
$\acute{f}(x_{n+1}) = x_n - \frac{f(x_n)}{\acute{f}(x_n)}$ for $n = 0, 1, 2, \ldots$.

$$x_{n+1} = x_n - \frac{2 \times f(x_n)}{\acute{f}(x_{n+1}) + \acute{f}(x_n)}$$

In the implicit formula, the indefinite integral involved in the following equation

$$f(x) = f(x_n) + \int_{x_n}^{x} \acute{f}(\lambda)\, d\lambda \tag{7}$$

Is approximated by the trapezoidal rule to obtain

$$\int_{x_n}^{x} \acute{f}(\lambda)\, d\lambda = \frac{x-x_n}{2}\left[\acute{f}(x_n) + \acute{f}(x)\right] \quad (8)$$

Put Eq. 8 into Eq. 7 yields

$$f(x) = f(x_n) + \frac{x-x_n}{2}\left[\acute{f}(x_n) + \acute{f}(x)\right] \quad (9)$$

Since $f(x) = 0$, therefore Eq. 9 can be written as

$$x = x_n - \frac{2\times f(x_n)}{[\acute{f}(x_n)+\acute{f}(x)]} \quad (10)$$

Take the next iterative point, that is put $x = x_{n+1}$ to obtain
$f(x_{n+1}) = f(x_n) + \frac{1}{2}(x_{n+1} - x_n)(\acute{f}(x_n) + \acute{f}(x_{n+1})$ or

$$x_{n+1} = x_n - \frac{2\times f(x_n)}{\acute{f}(x_{n+1})+\acute{f}(x_n)} \quad (11)$$

Eq. 11 is an implicit formula, which requires having the derivative of the function at the $(n+1)^{th}$ iterative step to calculate the $(n+1)^{th}$ iterative itself.
Thus, the resulting formula is

$$x_{n+1} = x_n - \frac{2\times f(x_n)}{\acute{f}(x^*_{n+1})+\acute{f}(x_n)}$$

where: $\acute{f}(x^*_{n+1}) = x_n - \frac{f(x_n)}{\acute{f}(x_n)},\ n = 0, 1, 2, \ldots.$ (12)

and x_0 is the starting value

4. Results and Discussion

Consider Eq. 6 is modelled in the form single-diode solar cell has obtained the following approximate solutions and the IM are applied with the first initial value x_0. In Table 1, the IM of the solution results (voltage V_{pv}; current I_{pv} and power P_{pv} of the solar cell) are presented and listed in this table when the load resistance $R = 1$.
Table 1 and Figure 3 Illustrate the obtained approximate results when $R = 1$

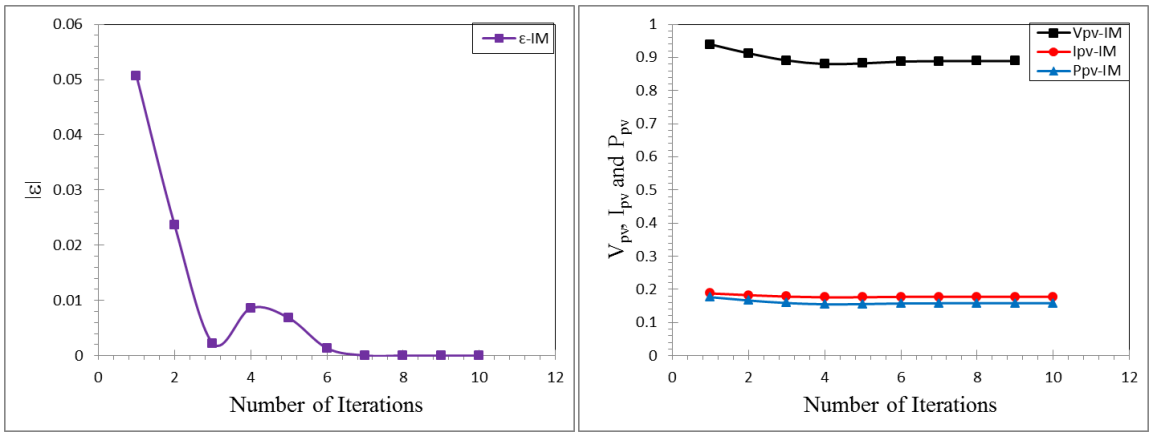

Figure 6. Voltage, current and power of solar cell with the absolute error values.

The obtained solution plot in the (no. of iterations)-ε-plane and the initial-output values prove that the proposed method IM have nine iterations indicated a fast behaviour. Parallel to this feature, it is noticed that the proposed method IM has a behaviour of the solution in the initial value x_0 with small error tolerance. Results from Tables 1-5 are showing that the suggested method IM exhibits low absolute errors after computed iterations which in turn demonstrating its efficiency.

5. Conclusions

This paper presents a new method to calculate the electrical parameter of the solar cell using implicit method. Values acquired from the proposed method IM were found to be sufficient and values for single diode solar cell were determined with fast convergence, more capable to determine these parameters towards establishing the final values.

Abstract. AlSb thin film was prepared on a glass substrate with a thickness of (200 nm) at room temperature using the thermal evaporation technique under high vacuum conditions (10^{-6} mbar**).** The effect of Cu doping at ratios (1%, 3% and 5%) on the structural and optical properties were investigated. The structural properties of the films were evaluated by X-Ray Diffraction technique (XRD) and atomic force microscopy (AFM). The optical properties of the films were measured using the (UV-Vis) spectra in the ranges from 400 to 1000 nm. XRD results showed that all the samples have a polycrystalline cubic structure, and the average grain size of AlSb increases with increasing the Cu ratios. According to the AFM analysis, it is noticed that the average surface roughness (RMS) of AlSb nanocubic thin film decreases with increasing Cu doped concentration. From UV–Vis absorption spectra, it is noticed that all the samples have high absorption in the visible region, and the direct energy gap values for the samples were 1.83 eV, 1.81 eV, 1.80 eV, and 1.78 eV for pure, 1% Cu, 3% Cu and 5% Cu respectively.

Keywords: High vacuum , Cu doped , micro strain , roughness , energy gap .

1. Introduction

The III-V semiconductors are stoichiometric compounds obtained by combining group III elements (essentially Al, Ga, In) with group V elements (essentially N, P, As, Sb) (1, 2). This gives us 12 possible combinations and important properties of the surface crystal planes (3). One of these compounds is AlSb. AlSb has a high energy gap, high electronic mobility, long wavelength, and conversion efficiency of more than 27% (4). Therefore, it is used in a wide range of applications such as solar cells, thermoelectric and opto-electronic devices. In addition, Al and Sb are relatively abundant, non-toxic and low-cost making AlSb compound an attractive material for device applications (5,6). AlSb also has potential applications as a detector of the radiation and as a material in high mobility hetero structures. Several methods have been used for the development of the thin films of AlSb like pulse laser deposition (7), co-evaporation (8), liquid phase epitaxy (9), hot wall epitax(10) co-sputtering (11) and doped AlSb thin films. Thermal evaporation technique is the most cost effective method among all other used techniques. In this work, AlSb thin film was successfully deposited onto glass substrates and doped with

copper at (1%, 3%, and 5%). The structural properties are evaluated by XRD and AFM techniques, and UV-vis was used to investigate the absorption spectra and calculate the energy gap.

2. Experimental

AlSb alloys have been prepared by mixing the a purity aluminum powder (99.99%) and antimony powder (99.99%) made by the Riedel-de Haen Chemicals Ltd., and putting in a quartz tube under ($1x10^{-2}$ torr), then the tube placed inside an oven at 1100 °C for 5 hours. The sample was cooled down using a slow cooling method. Thermal evaporation method was used to deposite AlSb thin films onto pre-cleaned amorphous glass substrate under high vacuum about (5×10^{-6} torr). The glass substrate was placed on the substrate holder above a molybdenum boats that carrying the materials, and the process was performed at a deposition rate of (0.5 ± 0.05 nm sec^{-1}). The films had been doped with Cu at ratios (1, 3 and 5) % .

The XRD machine (6000 SHIMADZU-Japan) was used to study the structural properties. The morphology of the samples (average diameter, roughness, and root mean square) were studied using the atomic force microscopy (AFM). The optical absorption was measured at a range of (400-1000) nm using (UV-VISIBLE 1800 spectra-photometer)

3. Results and Discussion

Figure (1) shows the XRD pattern of AlSb alloy. The peaks observed at 25.1943, 29.1411, 41.6611, 49.2683 and 66.4085 exhibit the formation of a polycrystalline cubic phase of AlSb which correspond to the (111), (200), (220), (311), and (331) reflection planes of. This result matches with the ASTM card number (00-006-0233). Table (1) shows a matching between the experimentally measured alloy and ASTM card (19) .

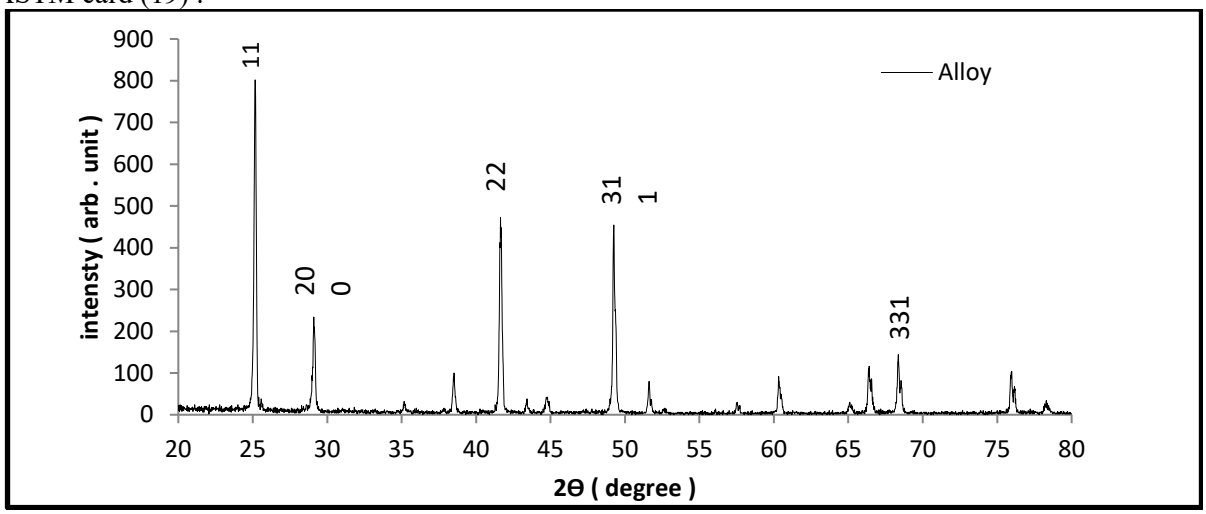

Figure 1. X-ray diffraction pattern of AlSb alloy.

Table 1. : A comparison between the experimentally measured alloy and ASTM card.

Standard				observed			
2Θ	intensity	d	hkl	2Θ	intensity	d	hkl
25.1354	100	3.54	111	25.1943	100	3.53195	111
29.0913	35	3.067	200	29.1411	27	3.06195	200
41.6030	75	2.169	220	41.6611	66	2.16617	220

49.2109	30	1.85	311	49.2683	68	1.84803	311
66.3862	16	1.407	331	66.4085	17	1.40662	331

the average crystallite size (D) can be estimated from the peak width with Scherrer's formula (12) :

$$D = \frac{K\lambda}{\beta_{FWHM}\cos\theta} \quad \ldots\ldots\ldots\ldots\ldots(1)$$

where D is the average crystal size, K is the Scherrer coefficient (0. 94), λ is the x-ray wavelength= 1.5406 A^{o} , θ is Bragg's angle and β the full width at half-maximum (FWHM) in radians.

The lattice parameter a of a cubic system is calculated according to the following equation (13):

$$a = \frac{d_{hkl}}{(h^2 + k^2 + l^2)^{\frac{1}{2}}} \quad \ldots\ldots\ldots(2)$$

where d_{hkl} is the inter-planar distance of each plane and (hkl) are Miller indices.

The dislocation density (δ), definide as the length of displacement lines per unit size of the quartz is expected from the formula (14):

$$\delta = \frac{1}{D^2} \quad \ldots\ldots\ldots\ldots(3)$$

The strain that made peak lengthening resulting from lattice deformation (microstrain) can be stated by Wilsok plan (15) :

$$\mu\epsilon = \frac{\beta_{FWHM}\cos\theta}{4} \quad \ldots\ldots\ldots(4)$$

The crystal layers number ($N_{\circ}$) calculated by using the following relation (16).

$$N_{\circ} = \frac{t}{D^3} \quad \ldots\ldots\ldots(5)$$

where t is the thickness of the samples

Figure (2) (a, b, c and d) shows the XRD patterns for pure and doped AlSb thin films at different Cu ratios (1%, 3% and 5%). From this figures, it is noticed that all samples have polycrystalline cubic structure with preferred orientation along (111) plane, and Cu addition causes slight offset shifting in the diffraction angle with a little decreasing in peak intensity and increasing the grain size for the film doped with 1% Cu. This film also appears less micro strain and dislocation density which attributed to the atomic radius of copper being less than the atomic radius of AlSb (r_{Cu} = 128pm, r_{Al} =143pm, r_{Sb} = 140 pm) (20). In addition, Cu may fill the interstitial spaces and reducing the crystal defects and hence reduce the roughness and the average diameter that seen clearly from the AFM images in figure (3) (a, b, c and d).

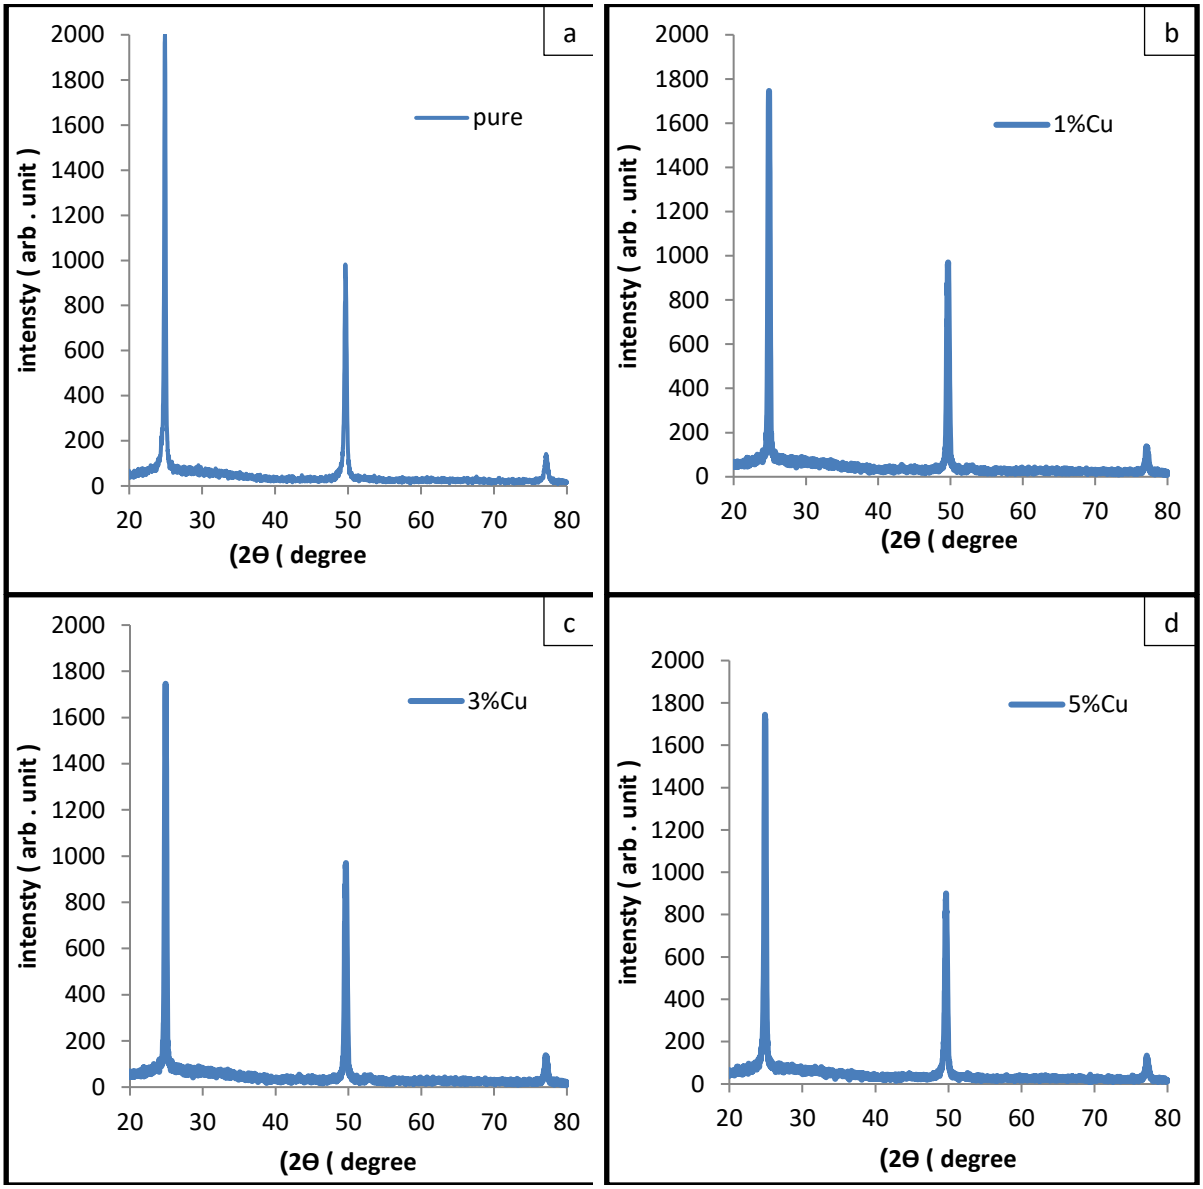

Figure 2. X-ray diffraction patterns of AlSb thin films for pure and doped samples.

Table 2. The grain size Micro strain , Dislocation density and Number Layers crystal for pure thin films and at different ratios of Cu (1% , 3% , 5%) .

sample	G.S	Micro strain)x10^{-4}(	Dislocation density×10^14	N10^{15}) x(Number Layers Crystal
Alloy	55.3907	6.603	3.25	1.176
Pure thin film	33.5776	10.923	8.87	5.283
Cu 1%	35.7995	10.153	7.802	4.359

Cu 3%	35.462	10.226	7.95	4.484
Cu 5%	34.8683	10.417	8.22	4.717

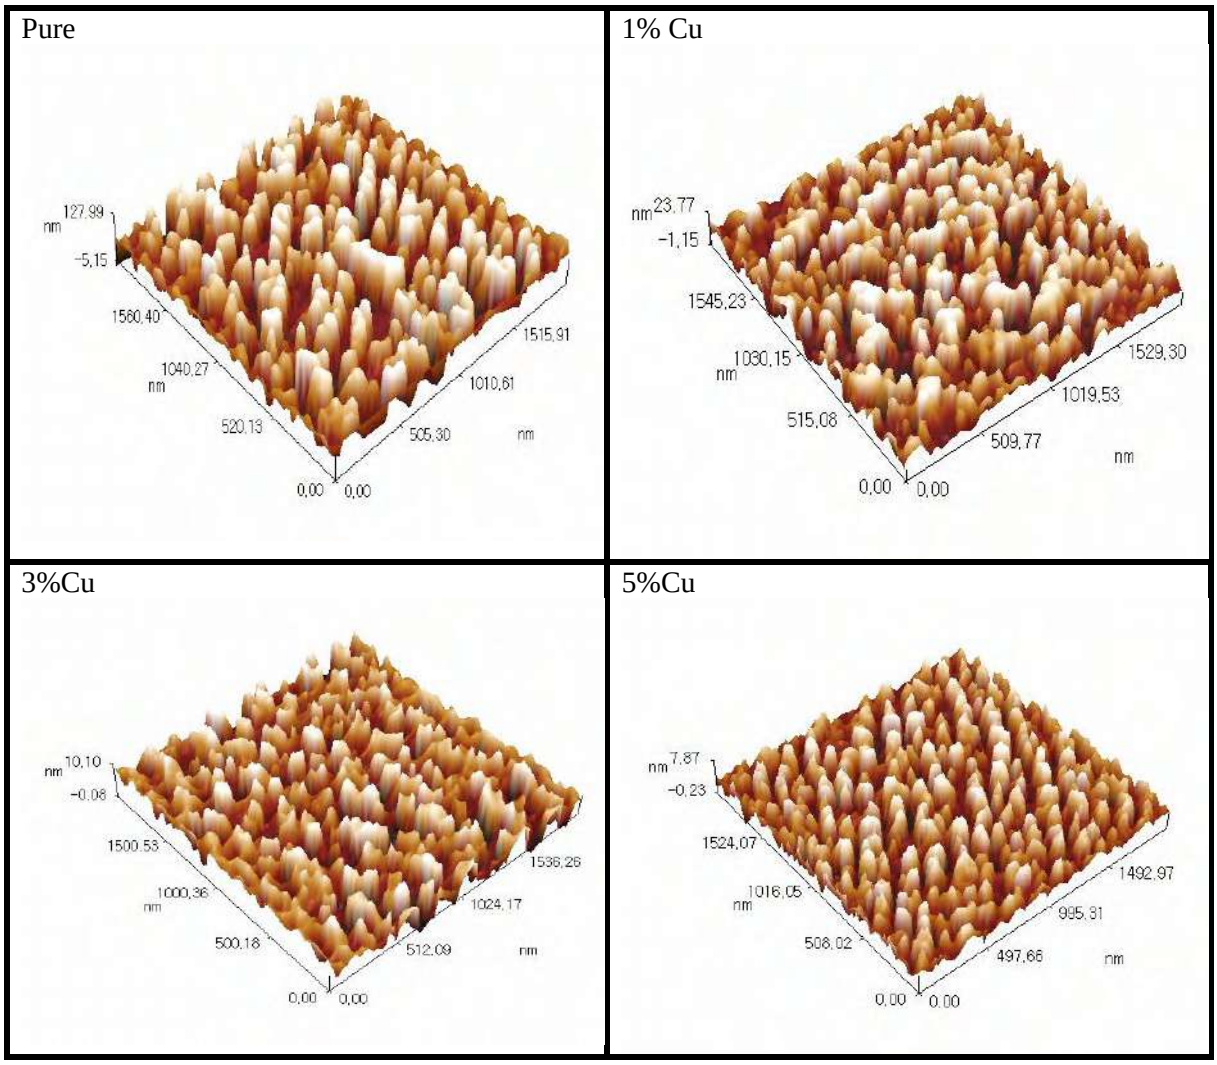

Figure 3. 3D AFM images AlSb / glass thin films pure and different Cu ratios

Table 3. Average Diameter, Roughness and root mean square for AlSb / glass thin films pure and different Cu ratios

Samples	Avg.Diameter (nm)	Roughness(nm)	r.m.s (nm)
pure	74.65	33.3	38.4
1% Cu	62.64	6.23	7.19
3% Cu	66.85	2.32	2.7
5% Cu	58.87	1.79	2.11

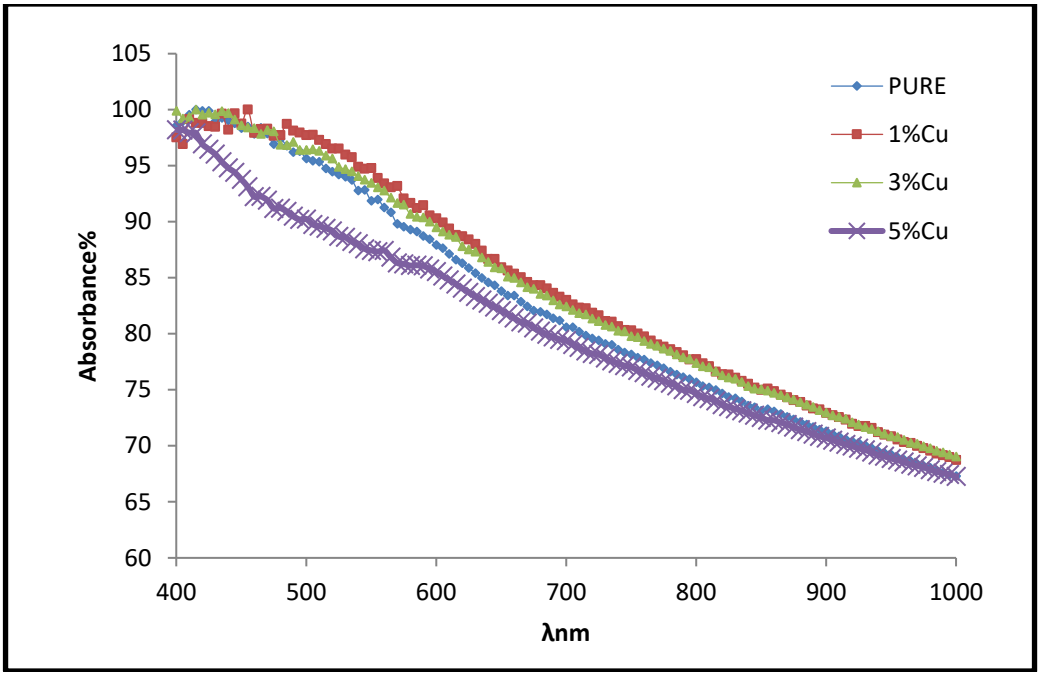

Figure 4. Absorption spectra of the AlSb thin films pure and different Cu ratios

Figure (4) shows the absorption spectra of the samples. We can see that all samples have a high absorption in the visible region, and the absorption coefficient (α) is given by the following equation (17).

$$\boldsymbol{\alpha} = 2.303 * (\frac{A}{t}) \text{.....(6)}$$

where A is the absorbance of the sample

To calculate the energy gap for the direct allowed transitions using Tauc equation

$$\alpha h\upsilon = B_o(h\upsilon - E_g^{opt.})^r \text{ .....(7) (18)}$$

where r = 1/2 for allowed transitions and r = 3/2 for forbidden transitions; E_g is the direct energy gap and B is a parameter that depends on the transition probability. The energy gap of all samples was calculated from figure (5) by plotting $(\alpha h\nu)^2$ versus photon energy for pur and doped AlSb thin films. The energy gap for direct allowed transitions decreases with increasing the Cu addition assigned to be 1.83 eV, 1.81 eV, 1.80 eV, and 1.78 eV for pure, 1% Cu, 3% Cu and 5% Cu respectively. These results can be attributed to the uniformity of the surface when adding copper. In addition, the copper added additional localized levels of electrons, hence reducing the energy gap.

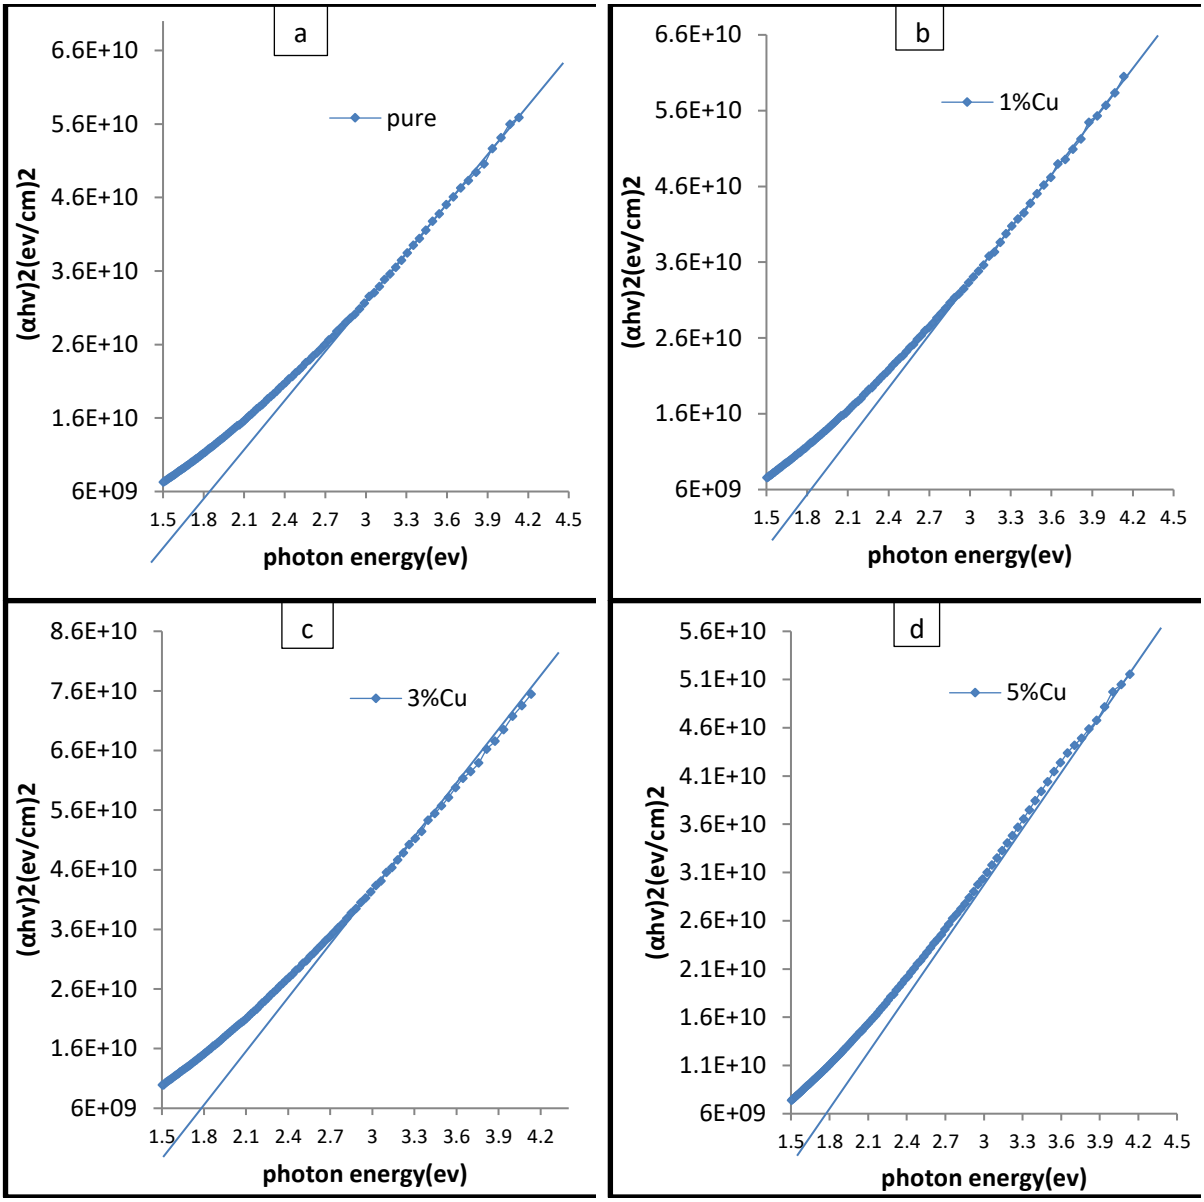

Figure 5. $(\alpha hv)^2$ verse photon energy for AlSb thin films pure and different Cu ratios

4. Conclusions

AlSb thin films were successfully deposited on glass substrates by thermal evaporation method. All the samples have a polycrystalline cubic structure, and adding Cu enhances the uniformity of the samples by decreasing the strain and increasing the grain size. The best structure property is found the film doped with 1% Cu, and the energy gap also decreases with increasing the Cu content.

Abstract. Powder metallurgy is one of the simple ways employed to produce alloys that are used in many technological applications. In the recent work, different contents (0, 5, 10, 15 and 20%) of silicon carbide ($\geq 63\mu m$) were used as a reinforcement material on matrix ((90, 85, 80, 75 and 70) % Cu-10% Nano-Al_2O_3). The mixture was milled by a locally made mill for three consecutive times (2, 4 and 6) hours. After that, a compressor with the highest compaction capacity (20 tons) was used to compact the mixture. The mixture was compacted in a steel die through applying pressure of 5 tons for one minute. After sintering samples at 900°C for two hours, mechanical tests including Vickers hardness, diametric compressive strength and wear were applied as a function of the grinding time. The results showed that the best hardness of (119.4 Hv) is reached for the grinding time of six hours and the reinforcement of (20% SiC), while the highest compressive strength was obtained for same time of grinding with a reinforcement of (53.3 Mpa). Concerning the rate of wear, its value decreased to the lowest value at the same conditions above (1.10368*10-7 g/cm). Accordingly, the best characteristic parameters of the results appeared at 900°C, the grinding time of six hours, and reinforcement content of 20%.

1. Introduction

Powder metallurgy is the process of producing metal materials whereby parts are produced in different forms of metal powders. Powders are compacted to obtain the required shapes, and then these resulting parts are heated with a process called sintering in order to create the interconnection between particles to obtain a rigid mass. The process of compaction is performed at certain compaction levels using a compressor with tools designed and manufactured for this purpose, which are die and compressor. The subsequent sintering process is performed at a temperature below the melting point of the matrix. This method is used either because of the difficulty of producing these alloys by casting process because their components are not mixed in the liquid state or because it is difficult to melt them [1]. The composite is a mixture of two or more materials that are strongly correlated with each other based on which the material acts as a single mass, so that it possesses intermediate properties of the component. This means that the composite material consists of two phases: matrix and reinforcement. The phases used are metal, ceramic or polymeric materials and the reinforcement phase is particles, fibers, whisker or sheets [2-4]. Copper-based composites produced with powder metallurgy technology are ranked third after iron, steel and aluminum-based products. The use of copper in powder metallurgy dates back to the 1920s [5]. Due to the high electrical and thermal connectivity, copper and its alloys have been widely used in thermal

and electronic applications such as the packaging of electronics, contactors and resistance welding poles. However, the relatively low mechanical properties in both high temperature and room temperature have limited or reduced the wide applications of pure copper. The mechanical properties can be improved by adding reinforcement materials for copper and its alloys. In other words, the copper-based and particle-reinforced composites may have many distinct benefits such as high mechanical, conductive properties and wear resistance [6]. The current study aims to improve the behavior of wear and reduce rubbing as well as mechanical properties by preparing a metal-based composite, which is copper, and reinforcing it by silicon carbide with different volumetric sizes using powder metallurgy. Thus, it can be used in many applications such as electric brushes, sliding mechanical bearings and other applications that require excellent thermal and electrical conductivity with low wear behavior.

Experimental Part

Raw Materials

The matrix used is copper manufactured by the Indian company (CDH) with grain size (44μm) and purity 99.5%. The first reinforcement material is Alumina α-Al_2O_3, manufactured by Changsha Santech Co., of Chinese origin with grain size (30±5) nm and a purity of ≥99.99%. The second reinforcement material is silicon carbide (SiC) manufactured by Merck the German company with grain size (53μm) and a purity of 99.90%.

2. Sample Preparation Method For Measurement

Powders were dried at a temperature of (200°C) for 2 hours to get rid of wetness and other volatile materials. The weights of each component mix were then created by following the weight ratios so that the alumina ratio was constant by (10%) for all mixtures. Silicon oxide percentages were (0, 5, 10, 15 and 20) % and copper was the matrix (90, 85, 80, 75 and 70)%. The weight was done using a Japanese-origin Sartorius electric balance with accuracy of (0.0001 g). After completing the grinding and stirring processes and obtaining a homogenous powder for three different grinding times, the samples were formed using uniaxial compaction in a steel die with a hardness of (60HRC). The stirred mixture was carefully placed inside the compaction die to avoid any movement of its parts. A pressure of (5 ton) was then applied for one minute to avoid the possibility of elasticity [7]. For this purpose, a Turkish-origin computerized hydraulic compaction of (HALIM USTA) type with a capacity of 20 ton was used to obtain cylindrical samples of (10) mm in diameter and 6 mm height. After compaction, the samples were not ready to perform tests and had weak resistance, which is green resistance. This requires care when transporting and handling until performing the sintering process. The sintering process was performed using a German-origin CARBOLITE oven at 900 °C for two hours. After that, the samples were removed from the oven for the examination process after the preparation of the sample surfaces.

3. Examinations and Measurements

3.1. Vickers Hardness (Hv)

Hardness is an important mechanical feature. It is known to be resistant to surface indentation [8]. It was examined using Vickers method by inserting the tool (a square-based diamond pyramid) by forcing a load of 500 g for (10 Sec). By calculating the diameters of the resulting indentation, Vickers hardness could be defined for the compacted sample by applying equation (1) [9]:

$$\mathrm{Hv} = 1.8544\ \mathrm{P}/\mathrm{D}_{\mathrm{v}}^{2}\ \mathrm{g}/\mathrm{mm}^{2} \quad \ldots\ldots (1)$$

where P is the force applied (g) and Dv is the average diameter of the pyramidal indent resulting from forcing a load on the surface.

3.2. Diametric Compressive Strength

Compressive strength was tested using Universal Testing Machine of (HOYTOM) type of Chinese origin. The sample was placed on the test platform. After that, a load was then applied to the diameter

of the sample until the failure occurred. The maximum load was recorded from the digital screen of the machine, knowing that the machine has the possibility to store the maximum value of the load before failure. Compressive strength was calculated using Eq. 2 [10]:

$$\sigma_D = \frac{2F}{\pi dh} \dots\dots\dots\dots\dots (2)$$

where σ_D is the compressive strength of crushing (MPa), F is the applied load (N), d is the sample diameter (mm), h is the sample thickness (mm).

3.3. Wear Rate Test

Wear is an important characteristic of the material surface, which is defined as the loss of material from the metal surface due to the friction of moving parts. From the initial trials, the amount of applied load was determined by (10N), using a fixed sliding speed (480 r.p.m). The period of applied load per test was 10 min. Wear test was carried out using a Pin-on-Disc device of Chinese origin found in the laboratories of the Department of Mechanical Engineering at Tikrit University. Table (1) shows the conditions of wear. A vertical load was applied by a (Pin) through a holder. The compacted sample was placed on a rotary disk. The reading was taken by a top sensor tied vertically on the arm holding the compacted sample. The reading was then moved to a digital scale fixed at the front of the device. The required loads were fixed at the top of the device as required. Wear rate was calculated using the weight method, which included calculating the amount of weight loss for each sample through weighing the sample before connecting it to the device and after the completion of the device operation using a digital balance by applying the following relation [11,12,13,14] :

$$W = \frac{\Delta W}{SD} \text{ (gm/cm) --- (3)}$$

where W is wear rate (g/cm), ΔW is the lost weight (g) which represents the difference in weight for the sample before and after operation, SD is the sliding distance (cm) which equals:

$$SD = \pi D n t \text{ --- (4)}$$

where D is the disc diameter (cm), n is the rotational velocity of the disk (rpm), t is the test time (min).

Table 1. Conditions of wear rate test

The rotational velocity of the disc	480 r.p.m
Test time	10 min
Vertical load applied	(10) N
The diameter of the test disc	60 mm
Disc hardness	62 HRC

Step of the Test Method

The compacted samples of diameter (10) mm and height (5) mm were prepared.
The samples were ground using sandpaper (400, 600, 800, 1200).
The sample was weighed before the test using a sensitive digital balance.
The rotational disc of the device was cleaned before starting the test.
The sample was fixed in its position using a holder designed according to the heights and diameter of the compacted sample. More than one sample was manufactured in the mechanical workshops in the General Company for the manufacture of medicines and medical supplies in Samarra.
Loads were fixed and a load of (15, 20, 25) Newton was applied vertically each time to the samples at a rotational velocity of the disk of (480 r.p.m).
The device was switched on after adjusting and resetting the test time.
The device was switched off after (20) minutes from the start of operation.
The sample was removed and weighed using the balance after the test.
The amount of weight loss was defined.
The relationship (3) was applied to extract wear rate for each sample.
The above-mentioned processes were reapplied to all samples. Wear rate was calculated for each sample by calculating the average wear rate for the upper and lower surface of each sample.

4. Results and Discussion

4.1.The Effect of the Added Content and Grinding Time on Vickers Hardness

Figure (1) shows the relationship between the change in the size ratios of silicon carbide particles and the grinding time on Vickers hardness after sintering at 900°C for two hours. It is observed that the hardness increases with increasing the content of silicon carbide and grinding time. Hardness increased after sintering from (38.1-84.2) at the grinding time of two hours. Then, it increased from (54.4-102.8) at a grinding time of four hours. After that, it increased from (74.6-119.4) at the grinding time of six hours for all cases at silicon carbide content (0-20%).

The increase in hardness as a result of adding silicon carbide particles and grinding is due to the high hardness of silicon carbide particles located within the range of (2500-3300) kgf/mm^2. In addition to the large number of interfaces formed as a result of adding reinforcement particles (SiC); as well as increased resistance to plastic deformation and increased residual internal stress due to the difference in coefficient of thermal expansion between matrix and reinforcement particles that produce a lot of dislocations. This leads to increase the hardness of the composites because silicon carbide particles of high hardness act as barriers to the deformation of the matrix and thus hinder the movement of dislocations. This makes stress greater in order for the dislocation to pass through the particles and thus requires an increase in the applied load. This in itself means an increase in the hardness values, and that the homogeneous distribution between matrix and reinforcement particles also has a major role in increasing the hardness. This is consistent with the results published in [15,16].

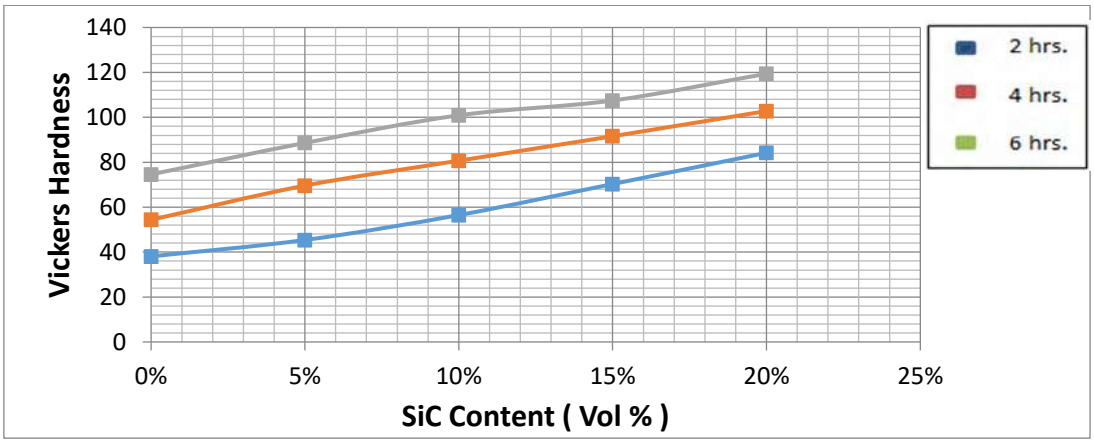

Figure 1. The relationship between the change in the size ratios of silicon carbide particles and grinding time with hardness after the sintering process.

4.2.The Effect of the Added Content and Grinding Time on Diametric Compressive Strength

Figure (2) shows the relationship between the content of silicon carbide and grinding time on the compressive strength of the composites with different silicon carbide ratios. Increased content and grinding time result in increasing the compression strength of the composite regardless the ratio of silicon carbide particles. The compressive strength increased from (10.6-28.8 MPa) for a grinding time of two hours, then it increased from (15.2-40.5 MPa) for a grinding time of four hours. After that, it increased from (22.4-53.3 MPa) for a grinding time of six hours for all cases at a silicon carbide content of (0-20%).

This is due to the high resistance of the reinforcement particles, which increased the composite hardness by increasing the content of silicon carbide. In addition, it is also related to the resistance of on-site deformations with high efficiency and then the formation of coherent samples with high compression strength. The high sintering temperature for two hours plays an important role in increasing the strength of the correlation between component particles of composites through good propagation and distribution, as well as increasing density and decreasing the ratios of porosity after sintering, which

leads to support and reinforce the composite mass. This is consistent with the results of the study in ref. [15].

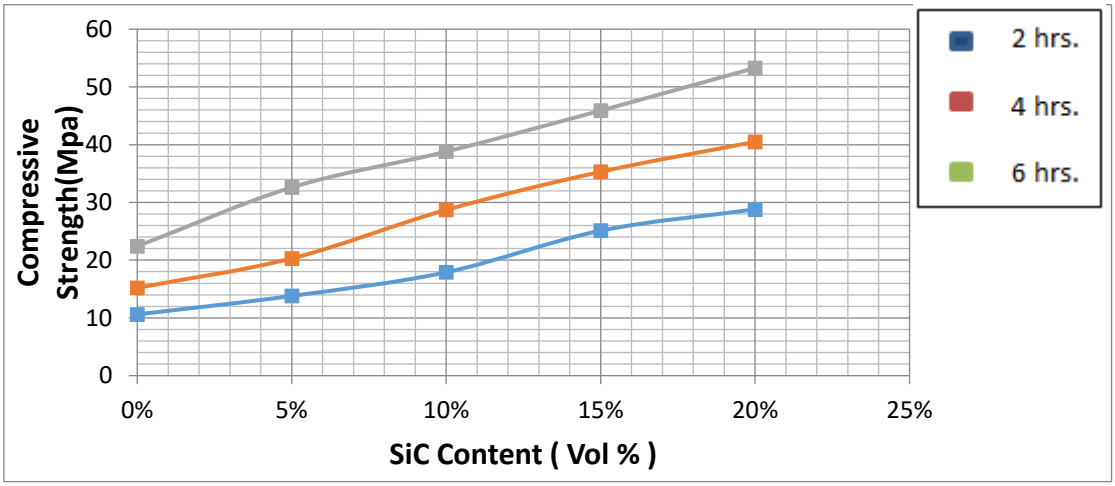

Figure 2. The relationship between the change in the size ratios of silicon carbide particles and grinding time with diametric compressive strength after the sintering process

4.3. The Effect of the Added Content and Grinding Time on Wear Rate

Figure (3) shows the relationship between the change in the size ratios of silicon carbide particles and grinding time with wear rate after sintering at 900°C for two hours. It is observed that increasing the size ratios added to silicon carbide and grinding time has reduced wear rate from ($3.53036*10^{-7}$-$1.81377*10^{-7}$) g/cm at a grinding time of two hours. Then, it decreased from ($2.42915*10^{-7}$-$1.54899*10^{-7}$) g/cm at a four-hour grinding time. After that, it decreased from ($1.94332*10^{-7}$-$1.10368*10^{-7}$) g/cm at grinding time of six hours for all cases at silicon carbide content (0-20%).

The low wear rate when increasing the content of reinforcement particles and grinding is attributed to the high hardness of composites when adding silicon carbide particles. Hence, the weight loss is low as a result of reinforcement of surface or ground with ceramic particles that hinder the progress of the dislocations. Therefore, stresses that are resisted by hard particles (SiC) would be generated and thus generating a dislocation density. The difference in the coefficient of thermal expansion has a significant role in this process that results in increasing the hardness by increasing the content of reinforcement particles. Moreover, wear rate decreases when adding SiC particles that cause increased hardness [17]. Wear rate is inversely proportional to the hardness according to the following relationship[18]:

$$V = K * \frac{Wx}{H} - - -(5)$$

where V is wear size, K is the coefficient of wear, W is the vertical load, X is the sliding distance, H is the material hardness.

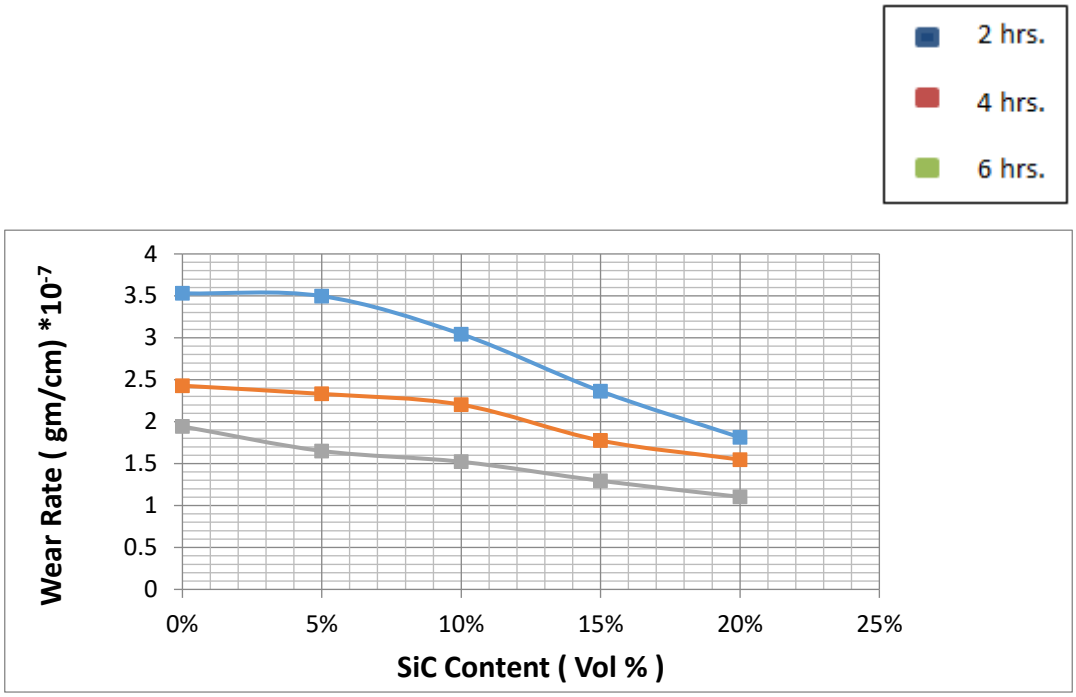

Figure 3. The relationship between the change in the size ratios of silicon carbide particles and grinding time with wear rate after the sintering process.

5. Conclusions

The important conclusion of the current research is the possibility of manufacturing models of copper-based composites reinforced by two materials of Nano-alumina by 10% and micro silicon carbide in different contents. After sintering at 900°C for two hours, mechanical tests were conducted. The obtained results showed that the best hardness was (119.4 Hv) at a grinding time of six hours and reinforcement (20%SiC). While the highest compression strength obtained at the same grinding time and reinforcement rate was (53.3 Mpa). As for wear rate, its value decreased as it was lower in the same conditions mentioned above ($1.10368*10^{-7}$ g/cm).

Abstract. In this paper, a lab-scale direct current (DC) glow discharges plasma system was used to adjust the surfaces of polymeric films. Characteristics of the plasma system have displayed under the discharge of three gasses (O_2, N_2 and Ar). DC-Plasma system has been used for the adjustment of polymethyl methacrylate surface as a function of treatment time and the types of gases. The modified surface was characterized in terms of crystal structure and surface morphology by the analysis of X-ray diffraction, scanning electron microscopy (SEM) and atomic force microscopy (AFM). A comparison between treated and untreated films was also made. The roughness and the root mean square (RMS) for pure PMMA films were continuously increased with increasing the exposure time for different gasses. SEM images observed degradation of the surface with granular spots due to the chain missioning and cross-linking effects. An efficient method of treatment for enhancing the surface roughness of pure-PMMA polymer is the using of argon plasma compared to O_2, N_2 plasma

Keywords: Polymers, PMMA, Plasma Treatment, Discharge Plasma.

1. Introduction

Polymers have been widely used in several scientific, industrial and biological fields like biomaterials, thin-film technology, adhesion, wear composites and friction, protective coatings, and microelectronic devices. In common, they were from successful applications that are widely requested because of private surface characteristics with respect to roughness, chemical composition, hydrophilicity, crystallinity, and cross-linking density [1,2]. Polymers are commonly used for a given purpose in many medical fields because of their bio inert characteristics and their ease of customizing their chemical and physical properties. Poly-methyl-methacrylate (PMMA) is a polymer with several attractive properties. It has environmental stability, low cost, and good optical properties [3]. In addition to its superior physical and chemical properties, PMMA is also being extensively used in numerous fields of life in recent years [4,5]. It is superior light transmittance, mechanical properties (impact strength, durability) and low density that superior to glass [6]. Simple manufacturing and low cost of production also lead to its widespread use. Its biocompatibility makes Poly-methyl methacrylate particularly desirable in medicine as a drug delivery agent, eye and contact lenses, orthopedic surgery, or dentistry [7,8]. A hydrophilic surface was observed to be formed by surface alteration and the creation of new functional groups on the surface by (DC) direct current plasma treatment [9,10]. It is significant that the surface modification of PMMA improves its biocompatibility and reduces implantation complications while maintaining its

excellent bulk properties [11]. In this paper, plasma processing has become one of the most promising strategies due to the combination of its advantages, including quick, environmentally friendly, solvent-free processing, low operational and maintenance costs [12].

2. Experimental Part

2.1. Substrate Preparation

By means of the spray pyrolysis method, Pure PMMA thin films were prepared. The glass sheets were sequentially washed in an ultrasonic bath with ethanol and acetone. Lastly, they were eventually rinsed with purified water and dried up. The deposition method involves decomposition (PMMA) spraying the solution onto substrates placed at a distance of 25 cm from the spray nozzle at 30-40 C° depositing temperature. Then, the process of spraying the liquid inside the spray device is controlled in terms of the spray time to 2 min, the number of sprinkles is five times, as well as the time period between one spraying and another was also 2 min.

2.2. Plasma treatment process and conditions

Surface modification of the PMMA films is achieved by treating incandescent Direct Current glow discharge plasma for different gases such as (O_2, N_2, Ar). The samples were cut into little slides with dimensions of (2x1) cm before the treatment of plasma. The samples were placed inside a vacuum chamber under a pressure of 10^{-2} mbar. The samples were backed on a glass rode and put in sit on spacing of 2.5cm from cathode. The time of treatment by plasma was changed from (5 - 30) min. The working parameters are listed in Table1.

Table 1: Working parameters for plasma treatment

Parameters	Values applied
Working Pressure	6.5 x 10^{-1} mbar
Electrode separation	5.5 cm
Power Supply	690 Volt
Flow rate of gas	750 cm^3/min
Exposure time	5 -30 min
Working gas	O_2 , N_2 , Ar

2.3. Characterization instruments:

X-ray diffraction (XRD) a non-devastating method for substances is commonly used to identify structural characteristics. The qualitative analysis may be conducted on the premise of peak height or peak zone. The peak angles may be utilized to decide particle diameters and the degree of crystallization. The X-ray spectra were gotten through utilizing copper filtered Cukα radiation λ=1.54060 (A) worked at 40 (kV) and 20 (mA) kind (SHIMADZU-6000) made in Japan. Field emission scanning electron microscope (FESEM), Hitachi (S-4160) with a continuous magnification capacity from 6x to 100,000x and Energy Dispersive X-Ray Analysis (EDX), referred to as EDS or EDAX, an x-ray technique used to identify the elementary structure of materials. Atomic Force Microscopy (AFM) is the device used for type inspection (AA3000 Scanning Probe Microscope SPM, NSC35/AIBS tip) that used to analyse the morphology and the roughness of the surfaces.

3. Results and Discussion.

3.1. Analyzing X-ray Diffraction

The x-ray diffraction spectra were used to analyse the crystalline structure of pure-PMMA films. It is clear that pure-PMMA film possesses no crystalline structure therefore, the XRD pattern reveals amorphous scattering around 2θ =12.50 and 25° from ratio of diffraction peak areas for crystal structure analysis before and after oxygen plasma treatment where the peak is even more intense for the treated film due to increased crystallinity. After oxygen plasma treatment and for different exposure times (5-30min), there were variations in the form or location of diffraction peaks in Figure (1). The XRD patterns

for pure- PMMA films before and after plasma-treatments for various gases (O2, N2, Ar) as indicated in figure (2). It is noticed an increase in the density disparity to regions for the pure-PMMA films treated by (O2, N2, Ar) plasmas over the same exposure period for untreated samples [13]. All these peaks' intensities also increased and contributed to the dominant disordering and thus affected the crystalline structure. In addition, due to the formation of the disordered structure in the plasma-treated PMMA polymer, the full width at half maximum (FWHM) of the peaks are broadened.

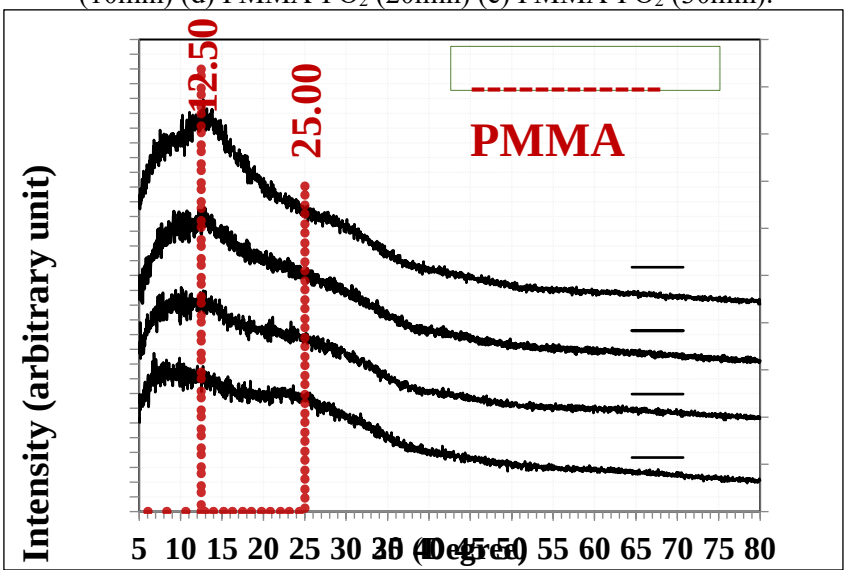

Figure 2. X-ray diffraction patterns of (a) PMMA-Pure (d) PMMA PO_2(20min) (f)PMMA-PAr(20min) (h) PMMA-PN_2 (20min)

3.2. Surface morphology analysis.

The AFM images for untreated and treated pure-PMMA films were shown in figure (3). Figure 3 (a) shows that the surface of untreated pure-PMMA film is smooth with the presence of conical protuberances and slight roughness. With increasing the exposure times of O_2 plasma treatment, the

surface roughness and the scale of the conical protuberances increased as seen in figure 3 (b - e). The roughness and the root mean square of untreated and treated pure-PMMA films are listed in Table 1. It is seen that the values of the RMS gradually increased with increasing the exposure time. The surface roughness is increased due to the removal of few top monolayers of the polymer films caused by the impact of plasma species on the surface [14]. The surface roughness increases the wettability and the bonding strength. The surface roughness Ra (evaluated from the AFM images) was 0.904 nm for untreated pure-PMMA, and it increased to be (3.98, 4.67, 5.33, and 4.16) nm after the treatment of 5, 10, 20, and 30 min respectively. As shows in table 2, it is noted that after the treatment with O_2 plasma, the roughness of the PMMA surface significantly increased during the treatment time, ranging from 5–30 min. The small decrease in Ra at a high treatment time value is possibly due to the cross-linking of newly formed surface radicals that may partially change its orientation and fill up the surrounding valleys, thus decreasing the roughness of the surface. This behavior agrees with references [15,16].

The influence of the cross-linking is observed by noticing the dependence of PMMA surface roughness on the ion energy. The surface roughness of PMMA films shows an opposite dependence on the ion energy following Ar, N_2, O_2 plasma exposure. The improvement by increasing the ion energy results in observing the variations in the surface roughness dependency on the ion-bombing energy. The results also showed that after long treatment with Ar and N_2 plasmas, the surface roughness of the pure PMMA films is much larger dispersed than plasma O2, since the processes of plasma etching can be lower in inert Ar and N_2 gases than from reactive gases. This result confirms that there was a greater etching process in plasma generated in reactive (or electronegative) gases than from inert gas as shown in fig4. This behavior agrees with references [17,18]

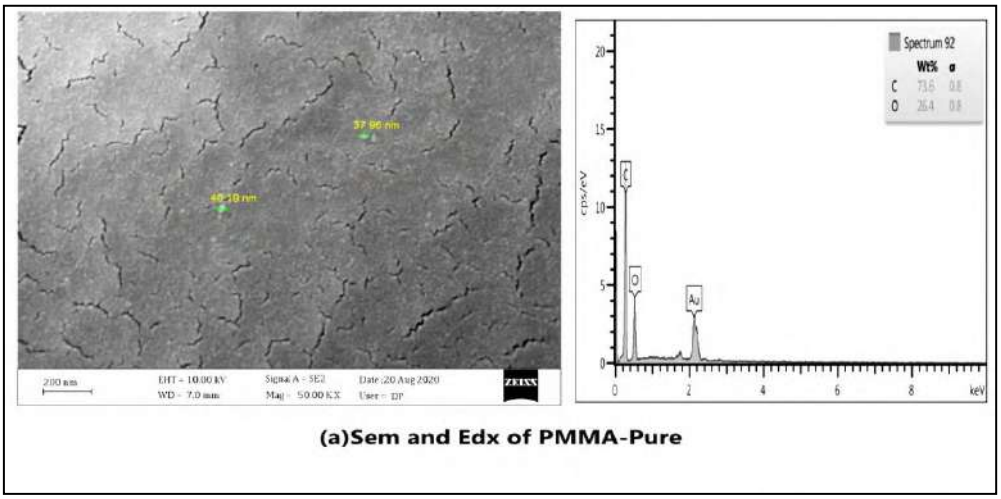
3.3. (FESEM) Field Emission Scanning Electron Microscopy.

SEM is ued for analysing the changes in the surface morphology of pure-PMMA films before and after plasma treatment. Figure 5(a) shows that the surface morphologies of untreated pure-PMMA films have relatively smooth surface. On the other hand, Fig. 5(f, g, h, and v) shows the surface morphology of treated pure-PMMA films under the best conditions for the surface adjustment. It can be noticed that there are clusters of particles connected to the surface. Oxygen plasma was used to modulate the surfaces of pure PMMA film. The plasma has changed the surface from the chemical composition and

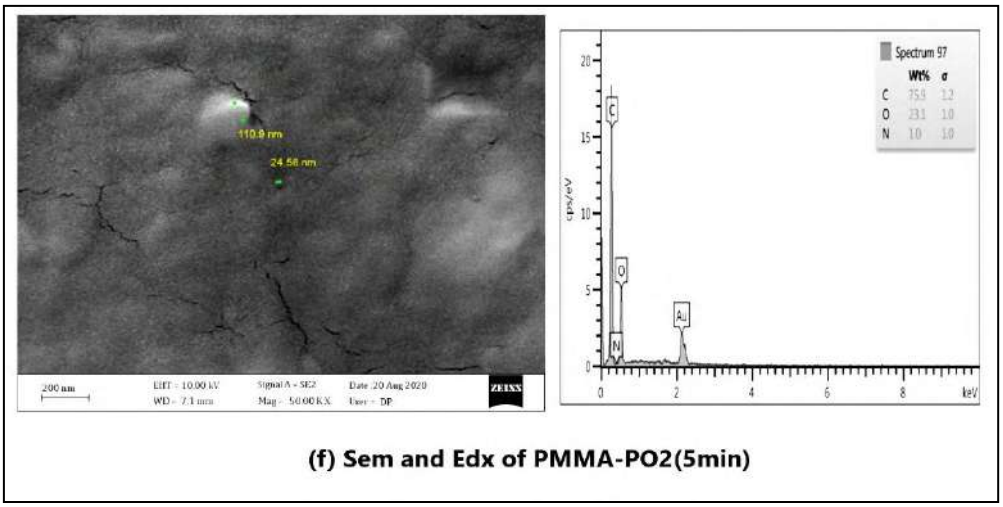
the morphology. It notes that increasing the plasma treatment time for pure PMMA films from (5-30) min causes a damage in the polymer chains, and the polymer becomes loosely packed, which in turn raises the etch-rate. Alteration of the etch-rate is high at the beginning and decreases at a higher period of treatment [19].

Table 4: Alteration of the etch-rate is high at the beginning and decreases at a higher period of treatment

Samples	Maximum Grain size(nm)	Mean Grain size(nm)
PMMA-Pure	40.19 nm	58,06 nm
PMMA-PO2(5min)	110.9 nm	123.18 nm
PMMA-PO2(10min)	98.58 nm	69.07 nm
PMMA-PO2(20min)	58.06 nm	44.66 nm
PMMA-PO2(30min)	35.73 nm	29.03 nm



(a)Sem and Edx of PMMA-Pure



(f) Sem and Edx of PMMA-PO2(5min)

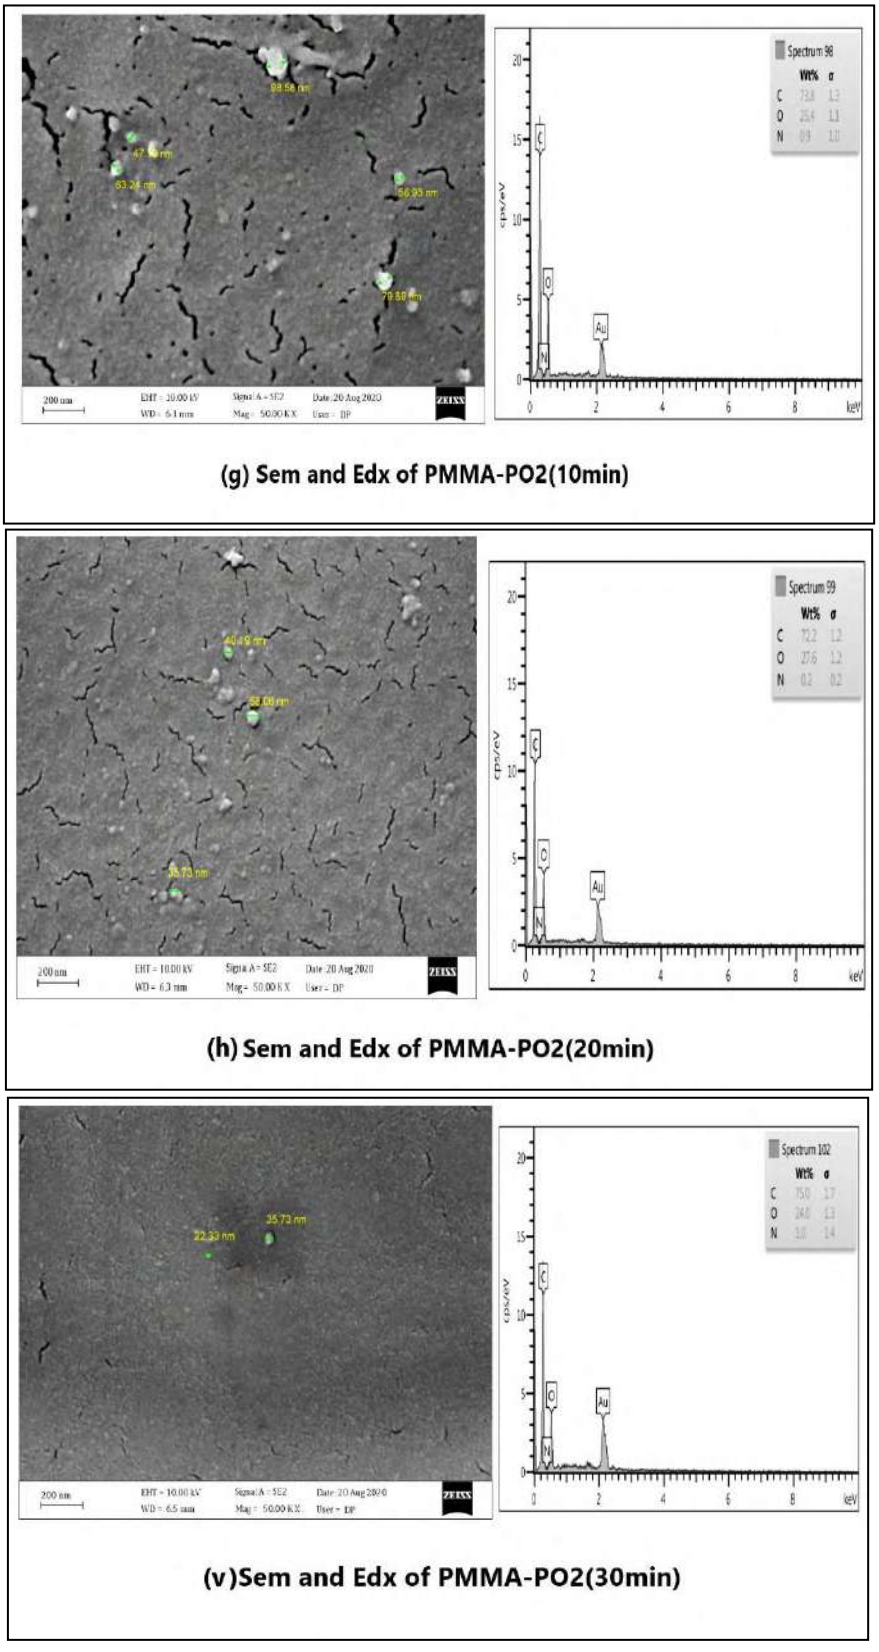


Figure 5. SEM and Edx measurements of (a) PMMA-Pure (f) PMMA-PO_2(5min)

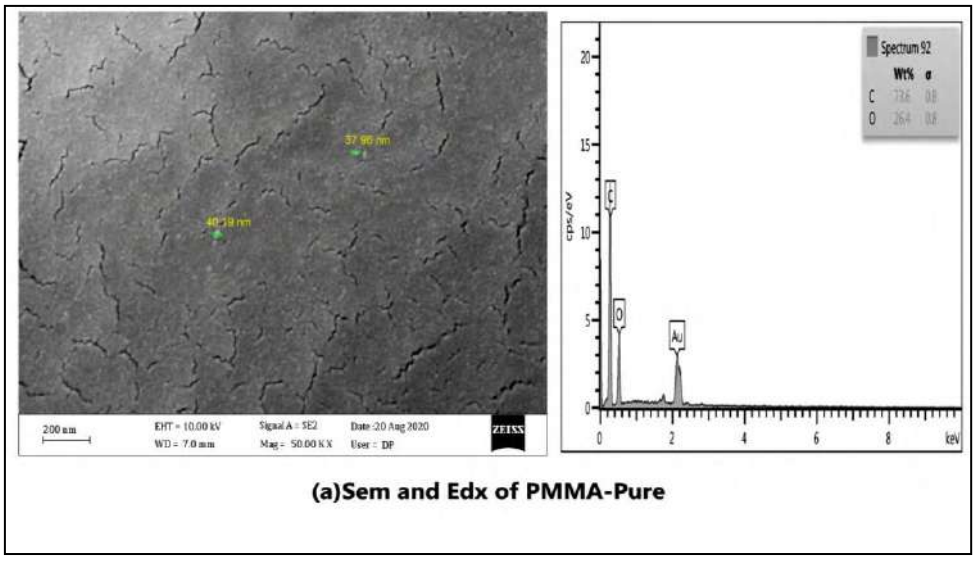
(g)PMMA-PO_2(10min) (h) PMMA-PO_2 (20min) (v) PMMA-PO_2(30min).

Samples are analyzed by SEM microscopy of the pure-PMMA films treated by plasma for different gases (O_2, N_2, Ar) at the same time of exposure. It is noticed changes in the etch-rate of pure PMMA samples after exposure to the plasma as shown in figure 6 (a, h, k, m). Untreated pure-PMMA sample has a uniform texture which undergoes major changes when exposed to plasma. While, treated pure-PMMA samples describe rougher morphologies with etching appearances and irregular-shaped textures. The surface texture produced is related to the differences in the etch-rate of amorphous regions coexisting in PMMA. Continuous bombing of reactive plasma species contributes to alterations the surface morphology. It is also known that the morphology for pure PMMA films dramatically altered during O_2 plasma treatment compared to the N_2 and Ar plasma etching. This behavior is correlated with a higher etch-rate of O_2 plasma in as seen figure 6h. It is noticed that the plasma of O_2 causes a major deterioration of the surface of the sample as a result of plasma etching mechanisms. Thus, N_2 plasma can be considered as an ideal alternative to boost surface properties with very low levels of degradation. This result is consistent with [20,21].

As a consequence of plasma processing, in addition to the oxidation effect of oxygen plasma, effective radicals (long-lived or met stable) present on the surface contribute to the restructuring of the surface. As described above, plasma etching, degradation and cross-linking are happen concurrently on the surface of the polymer. Cross-linking and degradation will control the polymer etching and thus the surface topography.

Table 5: Cross-linking and degradation will control the polymer etching and thus the surface topography.

Samples	Minimum Grain size(nm)	Mean Grain size(nm)
PMMA-Pure	40.19 nm	58.06 nm
PMMA-PO2(20min)	98.58 nm	69.07 nm
PMMA-PAr(20min)	523.3 nm	471.35 nm
PMMA-PN2(20min)	35.73 nm	35.73 nm



(a)Sem and Edx of PMMA-Pure

(f)PMMA-PAr(20min) (h) PMMA-PN_2 (20min)

4. Conclusion.

In summary, DC glow discharge plasma was used at various exposure times from (5-30min) for the modification of the pure-PMMA film surfaces by oxygen plasma where the results indicate increased surface roughness and increased crystallinity with increasing the exposure times. However, with the treatment for a long time, the value of the surface roughness significantly declined. While, the plasma treatment with various gases (O_2, N_2, Ar) for 20min at the same exposure time alters the surfaces in both of the chemical composition and the morphology. AFM and XRD studies showed an improvement in the surface roughness and increased the crystallinity. SEM images observed a degradation of the surface with granular spots due to chain missioning and cross-linking effects. An efficient method of treatment for enhancing surface roughness of pure-PMMA polymer is the using of argon plasma compared to O_2 and N_2 plasma.

1. Abstract:

This paper presents a cryogenic analysis of Junction less Under lapped Nanowire MOSFETs in lower technology nodes. The temperature dependent analysis is carried out to extract the DC figure of merits (FOMs) of the proposed nanowire MOSFET. The analysis is carried out to investigate the drain current associated with the device at different temperature. Further the analysis is extended with underlap length variation from source, drain and both sides. As the trans conductance plays a vital role in device performance estimation, so the analysis is further extended to calculate the transconductance for all the temperature variation and underlap length variation. With the introduction of gate metal under lapping, the sub-threshold behaviour of the proposed structure under different temperature is carried out extensively.

Keywords: Nano, MOSFET, Cryogenic, Underlap, Sub-threshold

2. Introduction

With an increase in the demand for portable electronic gadgets, semiconductor industry is thinking about more than Moore. Device miniaturization is no more an effective solution to bring the device into next lower technology nodes. As a result of which, different engineering techniques have introduced to bring down the scaling of the device into different level. As the device size is shrinking down to sub nanometre

regime, few unavoidable effects are affecting the device performances badly [1-4]. Although the device dimension is scaled down using some gate engineering or channel engineering techniques, but the effect of temperature on device performance is also an important topic of discussion. In spite of efficient characteristics in room temperature, the semiconductor devices need a thorough analysis in higher and lower temperature condition. Cryogenic analysis is the process of analyzing the behavior of a particular device at very low temperature [5-8]. Ultra low temperature changes the properties of material that instead changes the device also, which provides an interesting area for the researchers to do research. Multi-gate devices are considered as one of the best immune to reduce short channel effects [9]. Improved electrostatic controllability with multiple gates surrounding in different axis makes the device state of the art in semiconductor industry. Among different multi-gate devices, GAA MOSFET is considered as the leader in multi-gate MOSFET family in lower technology nodes [10-13]. The GAA MOSFET may be a rectangular type or cylindrical type (Nanowire), but the channel should be controlled by the gate from all the direction. GAA MOSFET with rectangular gate or channel is less efficient than cylindrical because of corner effect that reduces the mobility of the electron. At the same time, the potential developed on the device is a surface phenomenon and the electric field at the centre is zero, so the geometrical shape of the channel also affects the device performances significantly [14-16]. In case of conventional MOSFET, the source, drain and channel are having different doping concentration [17]. As a result of which, concentration barriers will be formed and junction will be created. Fabricating semiconductor devices with junction reduces the electron mobility and dissipates more heat as electron or hole has to overcome the doping concentration difference barrier. Apart from this miniaturization in MOSFET with junction takes more time and it's more expensive as the process involves scale down of each and every component. However in case of junctionless devices, scaling down of device in to different technology node is easy and cost effective compared to their counter parts [18,19].

3. Device Design and Simulation*:*

The simulation is carried out using Sentaurus TCAD (Synopsys) [20, 21]. The simulator includes various physics based transport model for semiconductor devices in different technology nodes. Along with drift diffusion model, quantum potential based models are also there to investigate the device performance in quantum level also. In order to investigate the temperature analysis for the device in higher as well as lower temperature, thermodynamic models are also there. Apart from these, this simulator also allows some gate engineering and channel engineering techniques to study the insights of various effects associated with semiconductor devices. In this work a junctionless Nanowire MOSFET is introduced in order to analyze the effect of the temperature in various FOMs of the device if some gate engineering technique is performed. The gate metal is under lapped from source side, drain side and both side to study the device behavior. The doping concentration of the junctionless device s kept as 1e18 with a metal work function of 4.3 eV. Apart from that the dioxide used is having a thickness of 2nm which is SiO_2. The underlap length variation is denoted as L_u and symbolized as $L_{u(S)}$ and $L_{u(D)}$ for source and drain respectively. The device dimensions of the proposed structure are given in table 1. The variation in underlap length and temperature is used to calculate the drain current at different conditions as shown in figure. Apart from this, the cryogenic analysis is carried out for a low temperature around 80K in order to have a clear insight into device performance at cryogenic.

Table 1. Device dimensions of the proposed structures

Device Dimensions	**Nano Wire MOSFET (Junction less)**
Channel Length (L_g)(10-60)nm	
Doping Concentration (N_S/N_D)Phosphorus(1e+18)	
Doping Concentration (N_a/N_d)Boron(1e+18)	
Oxide Thickness (t_{ox})(2nm SiO_2)	
Channel Thickness (t_{si})10 nm	
Source/Drain Extensions (L_s/L_d)	20 nm
Source/Drain Underlap ($L_{u(S)}$, $L_{u(D)}$)	(2,5,7) nm

4. Results and Discussion:

The analysis of the proposed device in terms of electrostatic potential and electric field distribution at a low gate bias of 0.2 V is illustrated in figure 2.

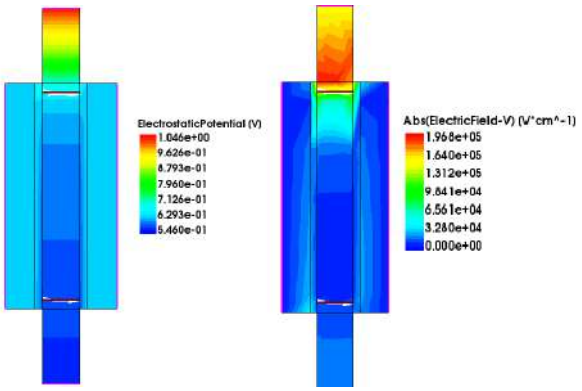

Figure 2. Cut section of the proposed structure in no underlap condition for (a) Electrostatic potential distribution (b) Electric field distribution at a low bias of 0.2V

The electro static potential and electric field are surface phenomenon. This can be observed from the cut section of the device shown in figure 2. From the figure, the distribution from source to drain and from outer metal gate to inner channel can be easily identified. The potential is developed at the interface of the channel and dielectric; whereas the electric field at the centre is assumed to be zero. However, the effect of drain bias can be seen near the drain side as the gate bias is very low. Figure 3(a) shows the transfer characteristics of the proposed model with source side underlap with various underlap length. With increase in underlap length, the transfer characteristic is bending down and moving away from

saturation as a very low temperature around 100K is applied to the system. The device transfer characteristics with temperature variation are illustrated in figure 3(b). From the figure it can be observed the shape change in transfer characteristic curve at different temperature can be observed. With the increase in temperature 8oK to 200K, the bending of the curve it getting more straighter and moving towards saturation.

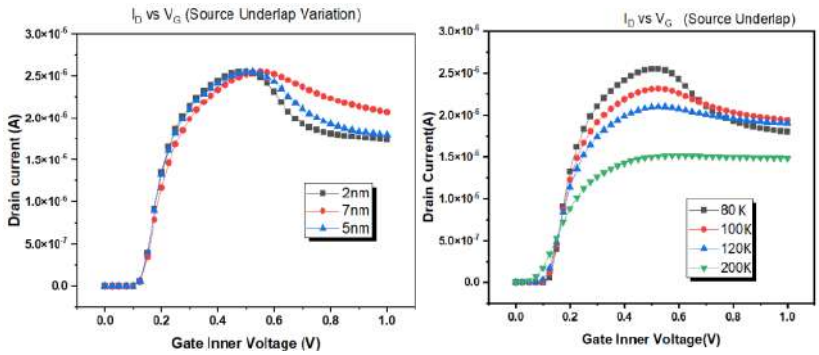

Figure 3. Transfer characteristics of the proposed structure (a) with source underlap (2nm, 5nm, 7nm) at a temperature of 100K (b) with different temperature (cryogenic temperature)

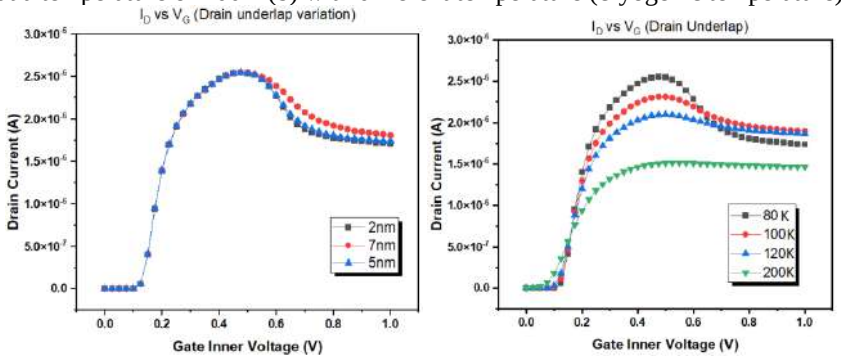

Figure 4. Transfer characteristics of the proposed structure (a) with drain underlap at a temperature of 100K (b) with different temperature (cryogenic temperature)

The transfer characteristics for drain side underlap with different underlap length and temperature is illustrated in figure 4(a) and (b) respectively. It is observed that in case of drain side underlap the characteristics are almost same for low under lap length up to 5nm. Once the underlap length is increasing, the change in the shape of the graph is well observed as shown in figure 4(a). Similarly, the transfer characteristics with the variation of temperature from 80K to 200K are shown in figure 4(b)

which looks similar to the source side underlap. As cryogenic analysis is the temperature analysis below 135K, so the device characteristics below this temperature is having different shape as shown in figure. The analysis is further extended to both side underlap. The characteristic curve thus obtained is similar to source and drain side underlap but it is more prominent while increasing the underlap length from 2nm to 7nm as shown in figure 5(a). Similarly the transfer characteristics at different temperature for both side underlaps are illustrated in figure 5(b). From the figure, the temperature dependency of the proposed structure can be easily identified from the figure. The temperature dependent mobility of the electron defines the characteristics shape when a gate bias is applied and with low temperature, its mobility will also get affected.

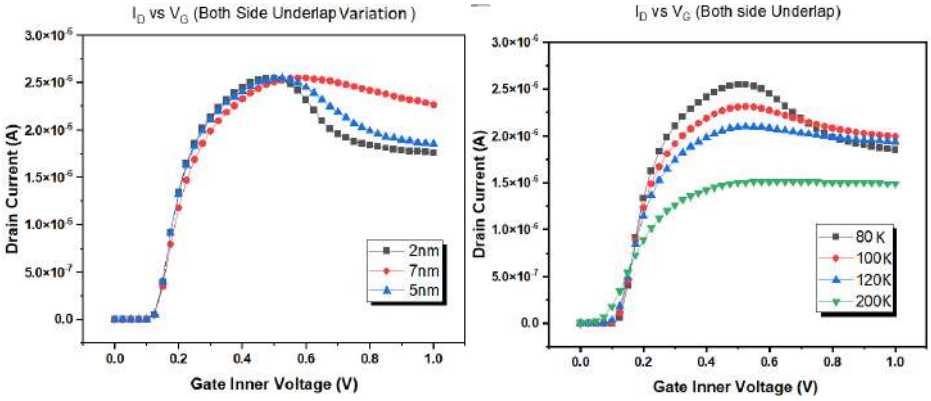

Figure 5. Transfer characteristics of the proposed structure (a) with both side underlaps at a temperature of 100K (b) with different temperature (cryogenic temperature)

The work is further extended to the transconductance extraction of the proposed model with source, drain and both side underlap. The trans conductance extraction for all the three cases are illustrated in figure 6,7,8 respectively. The maximum trans conductance for all the above three cases are higher in no underlap condition while reduces gradually with underlap.

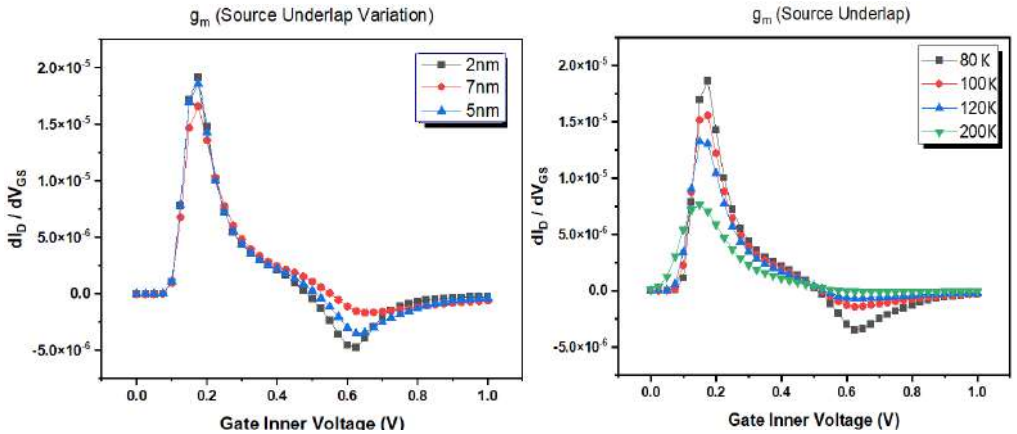

Figure 6. Transconductance of the proposed structure (a) with source underlap at a temperature of 100K (b) with different temperature (cryogenic temperature)

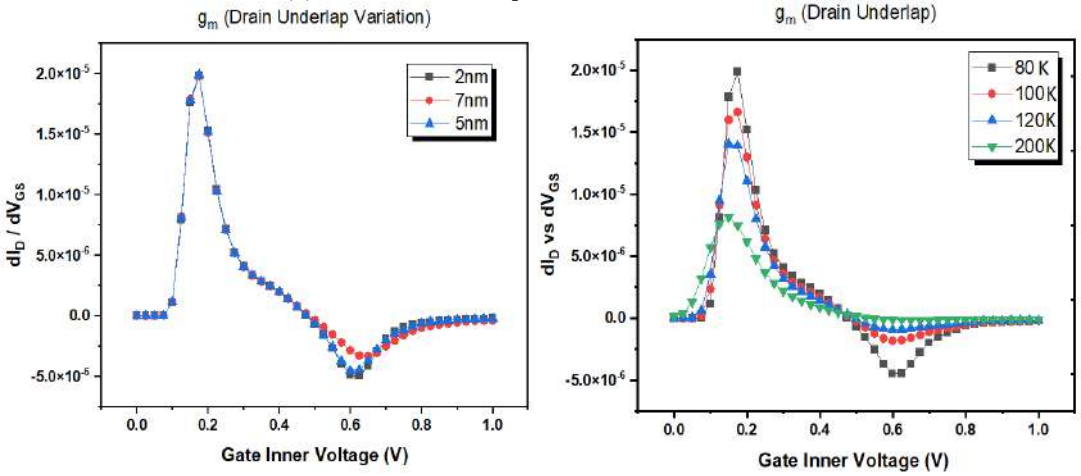

Figure 7. Transconductance of the proposed structure (a) with drain underlap at a temperature of 100K (b) with different temperature (cryogenic temperature)

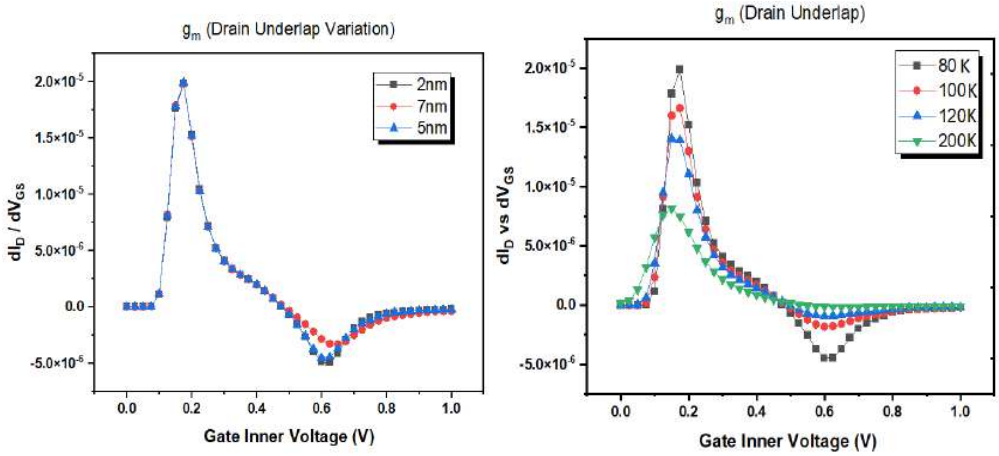

Figure 8. Transconductance of the proposed structure (a) with both side underlaps at a temperature of 100K (b) with different temperature (cryogenic temperature)

5. Conclusion:

The cryogenic analysis was carried out for the proposed junctionless nanowire MOSFET and the temperature dependency characteristics in terms of drain current and transconductance were investigated extensively. The analysis is carried out for a temperature of 80K to 200K with the underlap length variation of 2nm,5nm and 7nm. The gate metal is under lapped for these underlap lengths and the corresponding FOMs with underlap also investigated for clear cryogenic analysis.

Abstract : Web mining is the process of discovering important information and patterns in a weblog file. And contains loads of information. It consists of pages of various formats (HTML documents, images, etc.). And the data for this record is still increasing at a very high rate. So the process of retrieving information from it is a very difficult task. In order to obtain the required information from the network. This requires mining the weblog file. In this paper, the researcher conducted a review of previous studies and what researchers have dealt with in web prospecting. Explain web mining concepts. And how to obtain information and the visitors' patterns through the techniques and algorithms used in Web usage mining.

Keywords: Web Usage Mining, website, Web mining.

1.Introduction

The data On the Internet is enormous and is growing every day. The website is a cluster of web pages. Text, images, and videos may be included on web pages. And its they are connected through hyperlinks through which navigation takes place. Log files are created whenever users visit any website. The log file documents the full information about each user's access to the website. The size of log files is growing day by day because of the increased use of web pages[1]. The method for finding confidential information from a weblog file is named Web Mining. It is a branch of data mining. The purpose of it is to obtain information about the navigational activity and recall useful information from very enormous raw data, which can be expressed by several millions of event records in a log file. Weblog data includes various kinds of information so including weblog, web layout, and user profiles.[2] Web mining has been classified into three large topics of focus depend on which part with Web to be exploited which include: Web content mining, Web structure mining, and Web usage mining. The Previous three mining jobs can be used separately or can be combined with other jobs as they may contain web document links. Web mining is classified under data mining technology and its main purpose is to retrieve and extract knowledge from many documents and web services mechanically. As well to extract the required and exciting patterns from a series of huge data sets in the latest trend as well as used for traditional data mining. [3]
Web content mining its mining of this type is a very important area in analyzing users and the behavior of their web file content. Web content may contain very large amounts of multimedia data (images, video, animation, text, and document data in different styles such as pdf, etc., hypertext).

WCM is also used with a focus on visitor opinion extraction and sentiment analysis. Through which it is possible to locate comments in social media, blogs, and web forums. This type of mining is also used in education by extracting valuable information. Such as identifying consumer needs and etc. WCM is text mining and user opinion. It is one of the techniques that can be used to find important information from textual data. [4] . Web structure mining this type of web server mining uses a web file connection structure diagram and analysis of nodes in that file. The primary goal of mining the web structure is to extract the previously lost relationship between the web file pages. It is also used to generate a structural summary of the website and any page of the internet. It is also a mining method that will categorize web pages and show relationships between other websites. This technique is implemented either on a single page or on multiple pages (hyperlink). This technique produces structural information from a web server file consisting of a web graph with pages as nodes and hyperlink as edges [5].Web Usage Mining this type of mining focuses on customer knowledge and their collaboration with websites. This type is very important in extracting important information that explains the visitor's use of web pages [6]. That is, it is the process of discovering very important patterns of web usage data. Such as visitor access patterns and various other requests made by one or more users. The main objective of WUM is to understand navigation and browse through web pages. This is very important in enhancing the quality of services provided by websites. Business services, in the field of information and network security, fraud detection. And improve the structure and performance of web pages and servers [2] .

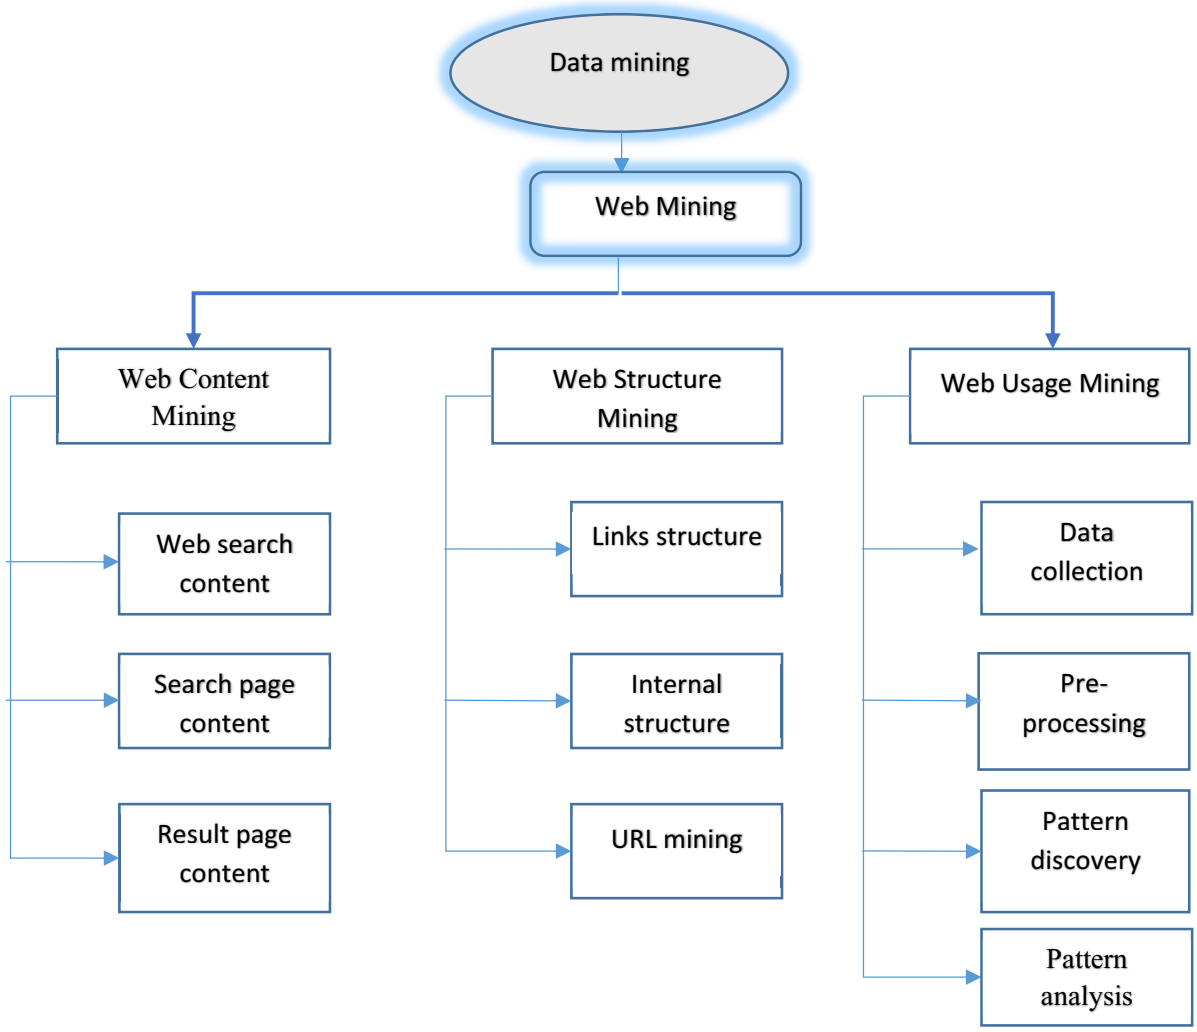

Fig (1) Web Mining Techniques [2].

2. Related Work

In this section, we uncover relevant work related to daily web use for big data results from web usage exploration. Which is a popular research area in prospecting for web usage, data analysis is essential to track user behavior in order to effectively serve users. Either in terms of security or website development and others.

According to. [1] The authors described mining on the web as the application of several techniques to extract data from web records. This log contains large amounts of data, so reprocessing is required to remove useless data. Two stages of pre-processing were proposed to clean up the data and identify the user using the proposed algorithms. A test was performed on a log file consisting of 500 records, after data cleaning it found 441record. Note the difference is not a little because it URLs used are Few compared to the size of big the weblog file. And this is the record used doesn't contain much needless content like jpeg, video, etc. After the user identification stage, it found 52 unique visitors out of 441 URL user records.

G. Shiva Prasad et al. [7] suggested that the neuro fuzzy typical Collecting bines the neural network and the customary (fuzzy notion). Where they used neuro based hybrid typical is effected to determine concealed patterns in the Web Log server special of (polytechnic web site). Web Log Pre-processing methods based on dimensionality reduction methods and collective methodologies were employed. The preprocessing phase eliminates all irrelevant, and blaring data, with a resultant Web Log size of 20% of the original log size. The (neuro fuzzy) grouped the users taking the same browsing patterns into set clusters. And the knowledge that has been collected after the analysis will can after that used from before the website for effective management and Personalize their website. This model was used to discover deviations in user behavior in many applications that require high security and high data privacy.

According to. [8] the authors described the web mining process in three imperative types (web content mining, website architecture mining, and web usage mining) that assist users to find valuable data. Each category has different algorithms and techniques needed to retrieve the information used in some applications such as fraud detection etc. Web content mining is helpful in terms of discovering the data from the (images, table, text, etc.). Web structure mining categorizes dealings between related Internet pages. Web usage mining is a too imperative kind which stores the user entree data and acquires info about a candid user of records. everybody methods may have some benefits and drawbacks. But they can be drawbacks better by additional studies.

R. Roy et al. [9]they conducted a comprehensive survey of mining methods on the web log document initial with weblog data sources which contain of only a text file. The information stored in the web log consists of a huge amount of useless data and noise, so this huge amount of data requires a pre-processing process for this record in a distinctive way to identify the problems in the web log document and also clarified the process of identifying the customer through (Client Identification IP address, by cookies, user data, site topology, and by authentication information).

According to. [10] the authors presented the technique of Web Usage Mining containing phases: Data Collection, Pre-processing, Pattern Discovery, and Pattern Analysis. They suggested a web history pre-processing algorithm where each page was assigned a specific token. According to this symbol and frequency, a technique can be applied to extract data (Classification, Association Rules, and Clustering) and reach that the highest and lowest value can be detected according to the frequency of accessing the page. Can simply learn the highest and lowest value.

Several researchers are shown in.[11] They used a method to improve the prediction of the next webpage Based on visited web pages by assigning top web browsing profiles for interested visitors. And it is recommended for current users interested in similar sites visited. They used a window sliding method with size N over the navigation session. Using the CTI dataset, The experimental results show a higher prediction accuracy for the pages of the next visit.

C. E. Dinuca et al. [12] Had explained that the session has a very important role in the reprocessing process. Also, most session delimitation algorithms use constant values to define the end of the session. He mentioned why using constant values causes errors in defining sessions. They propose a new method for identifying sessions based on average visit time for web pages that they implemented in Java programming language using NetBeans, IDE, which are two algorithms for identifying sessions. The former uses a constant value of 30 minutes to indicate the end of the session and the second using the

average time spent by users on their website pages. Was chosen the NASA log file available online to apply the suggestion.

Smriti Pandya et al. [13]They proposed a system interested in investigating serial mining techniques for access patterns with high efficiency and effectivity for web usage data and then using the pattern mined to match and create web links across the Internet. This usage data affords the trails leading to edited Web Pages Where this system has been taken advantage of in predicting the needs of the user and thus the use has been improved through the appropriate guidance of the web visitor to the important pages that are similar to the sites he is trying to reach.

Mr. Jitendra and et al. [14]presented a study showing reviews of different data to several researcher's processing methods. Such as the compilation and cleaning of data, Identification of users., route completion, and session determination. In addition to the advantages and disadvantages of these methods, which will be beneficial to society. To choose one or more of the available techniques for an effective pre-treatment. For more specific and consistent outcomes. As well proposed a complete preprocessing method that will enable analysts to convert any web server record set into an organization file (table, text) in the database. After comparing them with the preprocessing techniques used by other researchers, it showed more accurate results and Minimum preprocessing log file size.

Sucheta V. Kolekar et al. [15] they Submitted a proposal for the user's learning styles, by describing the learning behavior in the e-learning portal via Web Log Mining. The learning styles are then assigned to FSLSM classes. Provided that Each class is provided a learner with the appropriate contents and interface for the group He used the algorithm Fuzzy C Means (FCM) is used for collect educational, behavioral data captured from FSLSM classes. This method processes previous web data and converts it into (FCM) format, then defines unique sequences for each learner according to their sessions. Where it divides the sequences into eight categories based on the learning objects of the class, the work describes a methodology to automatically detect and identify the learning styles of learners using the Web Log Analysis approach where the validity of the algorithm was verified and compared with other, and the result was shown that it performs better in providing the contents and the adaptive interface for a new learner.

K.SELLAMY et al. [16] they provided a preliminary study of web mining, from several aspects (tools, techniques, applications). They proposed an approach to analyze and compare the skills taught in university or other studies, and the skills required at work. The aim of the study is to apply the latest methods of web data mining in the field of education and work.

The authors in the paper. [17] presented they a two algorithm that analyzes visitor behavior, And preprocessing the website visitors, Where Used the (HDD and CFPMA)algorithms, the first is used to filter and organize the appropriate information. And the second to mining the repeating pattern(CFPMA) to obtain recurring patterns from weblog data. In the present algorithms, repeated patterns mining is performed depending on the support threshold limit so that the accuracy is low, and the implementation period is high. But with this method. Based on the conviction threshold value, the session, and clustering in the weblog file. Focused the job on the weblog file format, pre-processing, and assembly, and pattern creation techniques.

The authors in the paper .[18] Presented a new approach to web usage mining using (Case Based Reasoning). by used clustering algorithms for titular web data. And it is founded on the reprocessing of previous labor Experiments. Thus, the previous experience could be an effective guide for Solve new problems. Web customization Which has the ability to adapt the next set of pages visited with individual users according to their interests and navigational behaviors has been proposed. A number of components of the proposed architecture are, Basic log preprocessing, methods of pattern discovery (By Reasoning Based on Case and similarity from peer to peer, Clustering, Association Rules Methods for Mining), In this study, a new predictive approach was introduced using CBR Method and mining of web use, which gives the user a choice to navigate to the next page. This technique gave high results compared with previous methods.

The authors in the paper [19]. Very big information the internet and tremendous resources. It has become imperative to determine the behaviors of website visitors through web history mining. To improve website performance and predict which page the user is likely to visit. And by searching, first in the similar cluster, then in similar sessions in the same cluster. This, in turn, causes an increase in the time of comparison with previous sessions when the data block is very large. In the study, they proposed three strategies (Least Frequent Ones Leave, First come First Leave, Timeframe Leave) for disposing of old sessions in order to replace them with new sessions (candidate sessions for prediction). When implementing the proposed methodology, the result was lower at the time of comparison and higher prediction accuracy.

Table 1. Brief description of data and web mining for previous studies

No.	Year	Authors	Technologies used	Focused on	Remarks
1	2014	P. Verma and et al. [1]	Two stages of preprocessing were proposed to clean up the data and identify the user using the proposed algorithms.	Data cleaning User identification	After completing the pre-processing stages, patterns will be detected that help in inferring user access patterns.
2	2015	G. Shiva Prasad et al. [5]	A hybrid model by on neural noise is used to discover knowledge in weblogs.	neuro-fuzzy model to discover hidden patterns in the weblog.	This model was used to discover deviations in user behavior in many applications that require high security and high data privacy.
3	2018	Hamid et al. [6]	The three types of web mining (Structure, Content, Usage).	Web usage mining(tools, techniques).	Web exploration is very useful (explore data, find out about visitor patterns ...)
4	2019	. Roy et al. [7]	Use detailed preprocessing to improve the quality and effectiveness of weblog data.	Transaction Identification.	Pre-processing of the log document is important to improve the productivity and ability to retrieve the log document information.

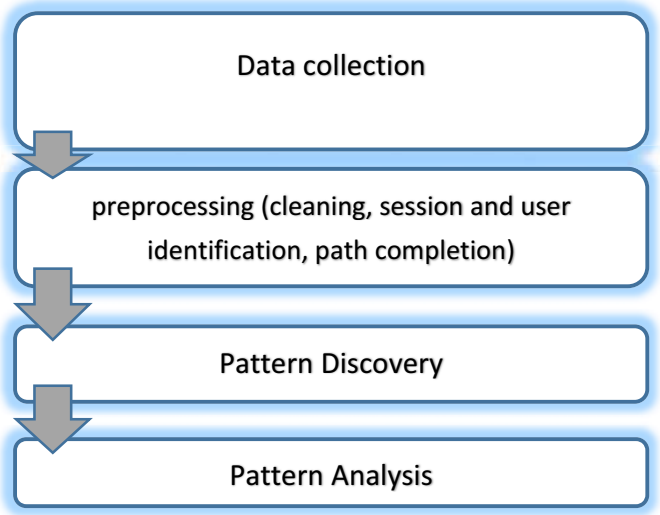
5	2018	Mehra and et al. [8]	Use web usage mining technology with web history pre-processing algorithm.	Implemented the algorithm in java programming language.	Be funded that most popular page and least popular page.
6	2011	Y. Almurtadha et al. [9]	They used the N-size window sliding method on the mobility session using a CTI dataset.	Improved prediction for the next visited web Pages is recommended for the current anonymous user.	A system with higher predictive accuracy was found on the following pages compared to previous systems.
7	2012	Dinuca et al. [10]	Using (NetBeans, IDE) which are two algorithms for identifying sessions.	It proposed a new method for identifying sessions based on average visit time for web pages that they implemented in the Java programming language.	In the first algorithm, they used 30 minutes for the session. In the second algorithm, the time depends on the page because it used the average visit.
8	2015	Pandya et al. [11]	They proposed a system interested in investigating serial mining techniques for efficient and effective access patterns.	Mainly focused on investigating the accuracy and effectiveness of mining technology for web usage data.	The resulting patterns are used to match web links to create links to recommendations.
9	2015	Jitendra et al. [12]	Use preprocessing technology that enables users to convert a web server into a database in the form of an organized table or text.	Pre-processing methods consisting of data collection, cleaning, visitor identification, session, path, etc.	The web server contains irrelevant data, which is important to preprocess.
10	2017	Kolekar et al. [13]	They used the (FCM) algorithm to collect the educational behavior data and the (GSBPNN) algorithm to predict the learning patterns of the visitor.	This method focused on processing previous web data and converting it into a format (FCM), then defining the sessions for each learner based on their sessions.	Description of a methodology for automatic detection and identification of learning patterns through web history analysis.
11	2018	Sellamy et al. [14]	Use web server data mining algorithms and techniques.	The study focused on extracting web data from several aspects (techniques, tools, applications).	The main goal of the study is to understand and apply web prospecting and prospecting for education and employment information.
		El-Aziz et al. [15]	Presented they a two algorithm that analyzes visitor behavior, And	Focused the job on the weblog file format, pre-processing, and assembly, and pattern	The algorithm (HDD) is shown to filter and organize the appropriate information, either

12	2020		preprocessing the visitors.	creation techniques.	(CFPMA) is used to obtain repeated data patterns.
13	2020	Asadianfam et al. [16]	Introduce a new predictive method, using (CBR) to explore web usage mining.	The study focused on designing and implementing a method that could provide visitor recommendations for navigation pages.	The results indicate that 70% of the recommendations were accurate and helpful.
14	2019	P. M. Bharti et al.[19]	-Least Frequent Ones out -First Come First out, -Timeframe Leave.	The study focused on getting rid of previous sessions.	Accuracy and prediction time are close in the suggested and best first strategies.

3- WEB USAGE MINING

As the number of internet users increased, the use of websites increased to get the required information. This, in turn, led to more data usage of these sites. This data is stored in various formats in the weblog file in an unordered format. And to understand the contents and user patterns of these records. The web history is mined. One of the necessary mining methods is web usage mining. This method consists of serial stages [20].

Fig (2) Stages of WUM:[6]



1) Data Collection:

The web history data is in the form of a document file. The information is stored in various types of documents. It is available in the following:[6]

A- Web server log file: These logs contain server-side data. This data consists of the IP address, URL, byte count, etc. In most cases, this data is displayed in a standard configuration. The most prominent of them is the Common Log Format CLF : [6]

B- Web Proxy Server Log file:

It is an average web server that is between the client and web server. When the webserver receives the visitor request through the proxy server. The log file entries will be the proxy server information and not the original client information. Proxy servers keep a separate record for all information user [20].

C- User Browser Log file:

Browser logs are collected from the devices of visitors who access the websites. This user data is found by proxies that are imposed by some applications such as (JavaScript programs). Attached to a web page is used to take information from the visitor as a record of their navigation. This data requires the cooperation of the customer, who most often restricts the operation of (JavaScript programs) for security reasons of the user [6] .

2) Data Pre-Processing:

It is a very important step in web usage mining. After gathering huge amounts of weblog data from various sources it appears to contain a lot of outliers that must be removed. To obtain consistent and integrated data for use in later stages (pattern discovering, pattern analysis). stages on preprocessing the as follows: [6]

- Data Cleaning

The log file contains a lot of non-essential records that are not related to our work. Like server error messages. Specified by the status code that the server sends when the visitor requests certain content, a field is recorded for each state of the record on the web. Also, the entries that contain graphics files, images, and others of the extension (jpeg, jpg, gif) are deleted. All codes greater than 299 and less than 200 are removed. Because it is considered invalid and is removed from the log file as in fig (3). Also, deleted records that were previously browsed are removed. Browsing records for the main pages are also deleted. This is because their links are found in most web server logs [2].

SUCCESS	200 series
REDIRECT	300 series
FAILURE	400series
SERVER	500series

Fig (3) Classes of status code.

- User and Session Identification:

It is not important to know the identity of the visitor. But there is a need to uncover and characterize visitor behavior. The server records multiple client sessions. And as a visitor can visit certain sites frequently. This is done without any authentication mechanisms. In many web servers. Because some

users disable the cookies feature. View its privacy content. This results in the IP address alone is insufficient to identify the unique visitor. Therefore, other criteria are used with the IP address such as user agent and referrer [2] . As for defining the user's session, define it. A group of pages visited by the same visitor in a certain period of time. On some web servers the session time is limited to 30 minutes. After this period, the second session begins. It is possible for a single visitor to have one or more individual sessions on the same page [21] . Visitor activities are numerous and controlling them is important in facing many issues, such as detecting visitor behavior and others. Among the most important of these activities are the following [22].

Table (2) Visitor activities

NO.	Activity	Clarify the activity	Example
1	The most active visitors identified	The visitors with the highest activity are limited by IP address, number of visits, and country.	192.168.0.110 IRAQ NO. V 13
2	Time to spend a visitor	It represents the time that the visitor spent at a particular site and can be represented by a diagram.	3	Daily visitor activity	It shows the differences in visitor traffic on the site during a specified period. It is measured in bytes transferred to each user	Sunday 15 Hits 200 KB
4	Hourly transfer rate	It shows the amount of data transferred in units of time	Hours of day Hit D. T 15 35 244 KB
5	Number of visits per visitor	It shows the number of visits of each visitor and deduces from it what the visitor's interests are in certain sites without others.	NO. of visitors' Visits NO. visitors 3 45
6	Countries with the most visits	Most countries ranked according to the number of unique visitors.	Country Unique V United stated 23
7	Browsers	It ranks your visitors according to the number of hits per browser. It also shows the byte size transferred from each browser.	Firefox No. Hits D. T 78 200KB
8	Operating system	A visitor's entries is determined by the number of arrival the O.S is installed on the visitor's	Windows 10 , No. Hits D. T 66 205KB

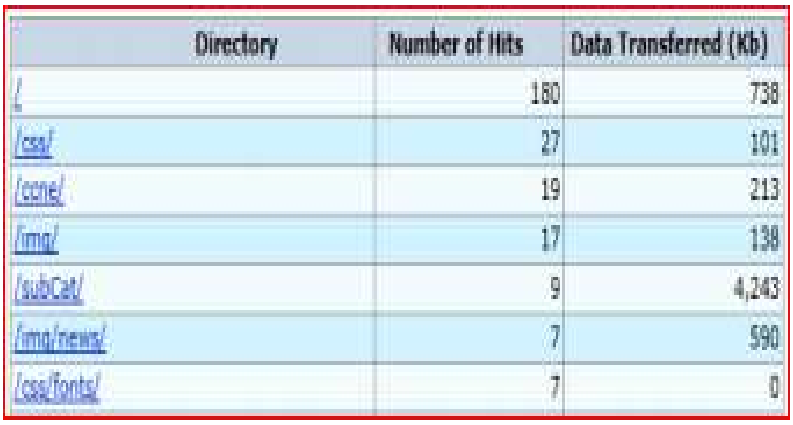
		computer. And the byte moved in the session.	

Table (3) User identification methodologies:

methodologies	Description of the methodology	Privacy risks	Advantages	Disadvantages
IP address & Agent	Assume when IP add & agent is unique this signifies that the user is unique	LOW	Available without technology	There is no guarantee that this user is unique
Embedded session ID	The dynamically created pages are used to link identifiers in the hyperlink	Low to medium	Since it is independent of IP address this makes it always available	Difficulty detecting duplicate users
Registration	The user enters the site directly	Medium	It can track the visitor and the browser	Visitors cannot register if it is not available
Cookies	By saving the identifier on the visitor's machine	Medium to high	Ease of tracking serial visits if it is for the same browser	It may be turned off by the user
Software agent	By downloading the program to the browser then it sends the used data	High	The data is accurate as it is for a specific location	It may not be accepted by the visitor

The process of controlling access resources and website security. Figure (4) shows the highly accessed or downloaded files arranged from highest to lowest. This is done by specifying the following [22].

- Define files with higher access
- The facts that have been reached
- Search engines
- Referring websites
- Security alert



Directory	Number of Hits	Data Transferred (Kb)
/	180	738
/css/	27	101
/core/	19	213
/img/	17	138
/subCat/	9	4,243
/img/news/	7	590
/css/fonts/	7	0

Fig (4) The most important directories reached.

- Path Completion

It is an important step in pre-treatment. Mostly it takes place after completing the session. The agent or client is mostly due to temporary caching due to the loss of access references for some pages [23]. Also when the real URLs are more than recorded in the server log. This indicates a loss of access to references to these pages. It is possible to reveal this when a visitor requests a specific page that is not related to the previous page (the previous request) for the same visitor. The referrer can refer to the register to find out which page the above application contains. If the missing page is in the visitor's last click log. It is a page not registered in the registry. This state indicates that the visitor browsed again using the (Back) button [20] .

3) Pattern Discovery

It is one of the most important parts of Web Usage Mining extracting data from the web history. After performing the data cleaning process, selecting the user and the session. The main goal of this part is to discover interesting patterns [8].

A – Statistics:

It is an important technique for finding useful information for any web history. And to know the content of the web history and the number of visits to clients in that record. The number of visits is calculated on the basis of each valid entry in the weblog. These restrictions may be posting, browsing, downloading. Because it helps improve system performance. Such as monitoring visitor activities, monitoring and checking pages and sites, and aggregating visitors based on their behavior [24].

B - Association rule:

This technique is used to find recurring rules and patterns in the data generated from the preprocessing stage of the weblog data. Such as the number of users' frequent visits to certain pages. The task of this technology is to understand the visitor’s requirements. This is done by discovering the relationships between the pages visited by a particular visitor to a specific website. Several algorithms are used as Apriori algorithm, To find recurring association rules [6].

C -Clustering:

Clustering is a method used to group certain elements (pages, users, etc.). Based on similar characteristics. Such as a grouping of webpages with similar content. Or Clustering a group of visitors with similar browsing behavior. Or collecting many users who visit similar sites and others. It is also possible to use the normalization process with Clustering. This will give better combination results. Because there are different ranges in the data point for each area. Clustering technology helps in deducing customer stats in e-commerce market operations. And provide customized web content based on individual visitors. Also, Clustering is useful in making indexes of websites on the Internet [6].

D - Classification:

This technique categorizes data elements into distinct, predefined categories. Related to a specific category. This technology requires extracting and selecting the distinct classes on which the classification is made first. Then, the classification process is performed.[6] The main goal of categorizing weblog data is to develop the log for visitors belonging to a specific category as opposed to aggregation. Because classification is a directed learning method (supervised learning). Of the algorithms used by this technique naïve Bayesian classifiers, decision tree algorithm [20].

E - Sequential pattern:

It is the conduct of analysis to find patterns in sequence through serial sessions. And by applying several algorithms such as SPADE, Apriori, etc. For example, a specific visitor. visited link A and then link B one by one at the same time. Using analysis for such a pattern, we can predict the suspected visitor. When visited in a pattern similar to the previous one .Through psychology used to uncover crime, predict shopping, advertisements, etc. [6].

4) Pattern Analysis:

It is the last stage of web usage mining. In it, knowledge is found in the detected patterns. Interesting patterns. And that by getting rid of inappropriate patterns. This can be done by applying a validation rule. To get rid of inappropriate patterns and uncover appropriate patterns [20].

A commonly used technique in pattern analysis is the OLAP (Online Analytical Processing Technique).Visualization methods, administrative advertising deals, It uses graphic patterns to interpret the file results in an easier way. As well as (the mechanism of using the knowledge query SQL). Which is used to analyze several reasons for the abnormal patterns of your visitors[6].

4- Web Usage Mining Advantages and Disadvantages:

A) Advantages:

WUM It has many important advantages that make it more attractive to many, including governments, organizations, and companies. This technology appeared in electronic commerce to develop private shopping, the results of which showed large volumes in trade and profits. In the field of security, government agencies and others use this technology to classify and combat terrorist threats. Through the ability to predict Internet fraud detection and sort and identify people and pages with a high-security risk. Helps companies find the best relationship with the customer by identifying exactly what they need. Through WUM companies can understand well the requirements of their visitors. And provide a faster response to the requests of the visitors. It is also very beneficial for companies in attracting and retaining useful customers for the company who can save the best production costs [20].

B) Disadvantages:

When using WUM on personal information shows some concerns and negative consequences including. Violating the privacy of the user's information if it is obtained or published, especially when the user is not aware of it. It is the main concern for some users when some companies collect data from people for a specific purpose, such as a job or work, and others. These entities may use the data for other purposes such as fraud through e-mail or other personal information. Some techniques may be used to classify individuals based on controversial characteristics such as race, sexual orientation, religion, or gender. These practices can be in opposition to the Anti-Discrimination Act. Some companies also sell personal data obtained from people's websites in various ways. [20].

5- CONCLUSION

Data mining is the process of discovering needed information. Web mining is a branch of data mining which is the discovery of the knowledge and patterns required of the sheer volume of web data. This enormous amount of data is reflected negatively in the web mining process. Because it contains a Data outlier. Therefore, a pre-processing and cleaning stage must be carried out before mining. The web mining process Classify into three main types (Web Structure Mining, Web Content Mining, Web Usage mining). Each type is used according to the user's desire and what is part to be mined. This paper focused on conducting a survey of previous studies in web mining and types. And explained web usage mining and algorithms and techniques used in this genre. Starting with data collection, preprocessing, Discovery, and Analysis of Patterns. And what are the Advantages and Disadvantages of Web Usage mining.

Fingerprint Image Identification Algorithm Based on Angle Direction of Objects

Fingerprint Image Identification Algorithm Based on Angle Direction of Objects

Diyar M. Witefee and Tawfiq A. Al-Asadi

Information Technology College, University of Babylon

E. mail: Dyarz2017@gmail.com

Abstract :Fingerprint identification is one of the most important biometric techniques utilized for determining the similarity between the matching images. This paper will be presenting a new identification technique depending on the angle direction of the objects contained in images. The performance of identification techniques relies on the quality of the image. The quality of fingerprint image may not always be well due to many reasons such as contain noise which hinders the clarity of image structures.

Keywords: Image of Fingerprint, Thinning, Minutiae based matching, Feature Extraction.

1. Introduction

Biometrics science is the analyzing of physical and/or behavioral characteristics that specific to each individual for identification the identity in a reliable and fast way by using of unique biological characteristics**.** It addresses a longstanding concern to prove individual's identity and individual's verification, by making use of what makes once different. Historically, applications that using biometrics are military access control, criminal or civil identification and technical framework. Today is including banking, retail, and mobile commerce.

Fingerprint is one of the most widely used biometric. It can be defined as the graphical flows of ridges in human fingers which are formed during infancy. According to researches, not even two people have the same fingerprints. Even the ten fingers of the same person differ with respect to their corresponding fingerprints. Fingerprint image can be used for many purpose such identification and verification.

In this study, the pre-processing is applied to enhance, morphology and thinning the fingerprint image then the local features (Minutiae) extracted; finally the fingerprint images are matching based on the angle direction of the minutiae points. Based on a specific threshold of the correct number of matching score the identification of the fingerprint image is determined.

2. Related work

Over the years, research on image identification has offered a lot of matching methods. Typical examples include the local and global methods like Minutia matching; correlation depended on matching, neural network-based matching and pattern matching.

- Manickam, A., Devarasan, E., Manogaran, G. (2019) [6] introduces a model to perform matching for latent fingerprints using Scale Invariant Feature Transformation (SIFT). Their model consist of two phases (i) contrast enhancement using a fuzzy set (ii) extraction of SIFT feature points

from fingerprints. Then matching algorithm is performed with *n*- number of images and scores are calculated by Euclidean distance.

- Alejandro Valdés Camejo and Javier Lamar León [7] used the application of the algebraic topology to present an algorithm for fingerprints verification. They defined local structures based on neighboring minutiae. The extraction of features is based on the homology variation of neighboring minutiae. In addition, a matching method is presented based on the topological information.
- Kimfung Liu and Wenzhong Shi [8] proposed a new developed computational fuzzy topology to define the topological relations among spatial objects. They used the value of a level cutting which represent the intersection between both boundaries with interior and the exterior. They submitted an approximation of these overlapping areas.

3. Research Methodology

Before performing the image matching, a pre-processing step is performing to increase the image quality (corrective measures). Many reasons caused low quality in the fingerprint images such as partial images, the problem of the sensors and the skin problems. Pre-processing step include the enhancement of the image, morphology and thinning process Then the step of feature extraction is performing which involve extraction the local features (Minutiae) and global features (core and delta). Often the images are different in rotation angle and scale space, and then the next step is the alignment step for the images to be matched. After the alignment step, the images will be in the same rotation angle and similar scale space. The final stage is the matching step, which is performing between the input image and images store in the dataset and then determines the similarity among them.

The proposed system, which is used for fingerprint images identification, illustrate in figure-1 consist of three steps:

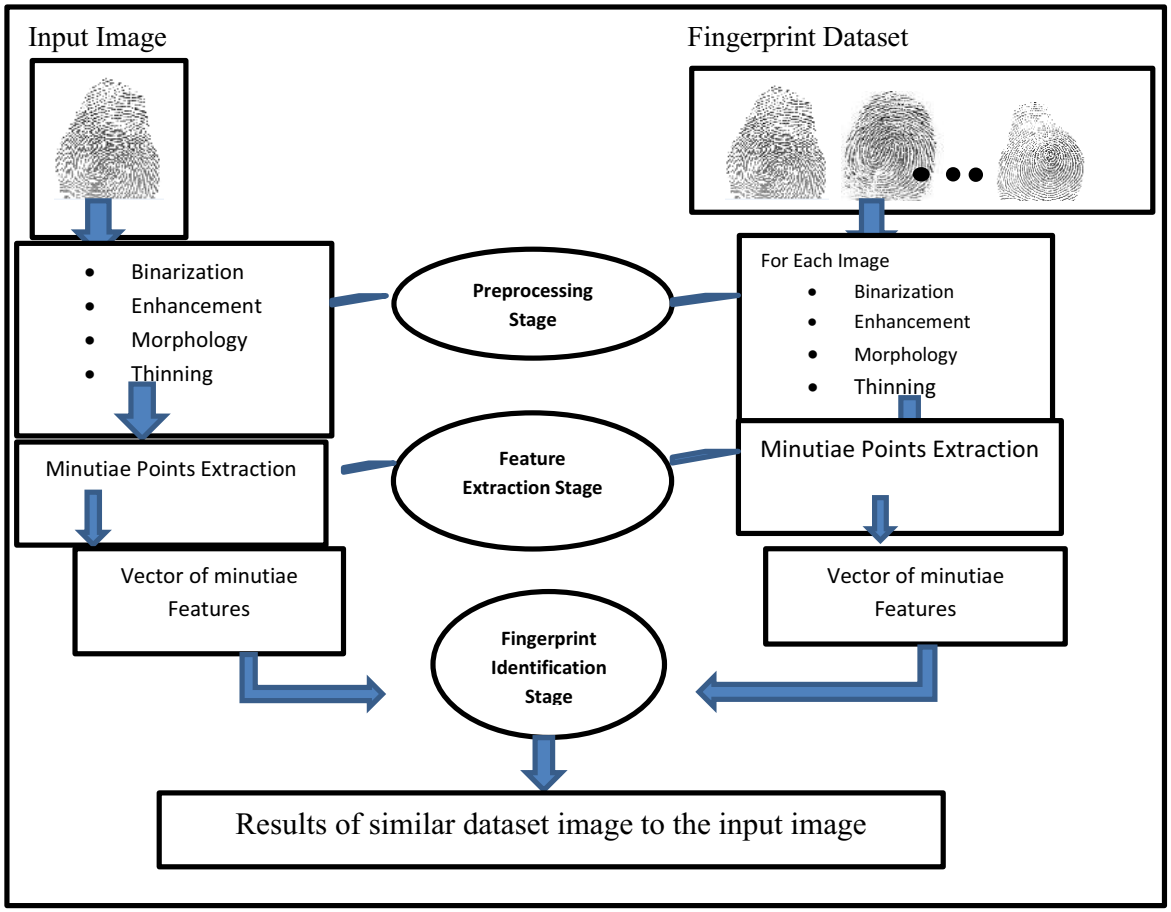

Figure -1 Block diagram of the proposed system

-The initial stage is the *pre-processing* stage of the proposed system, are clarified the following points:-
1-The input and reference fingerprint images are converted to a binary image: each pixel value in the binary image can be one of two values, either 0 or 255 value.
2-The binary images are enhanced by applying Gabor filters on it: Gabor filters are classified as filters that are sensitive to frequency and orientation, utilized for the analysis of texture and edge. The filter could be modulated by a Gaussian envelope and found the same frequency and direction as a sinusoidal plane.
3- Apply the morphology operations on the input and reference images to improve the enhanced images by focusing on the important objects
4-Perform Thinning operation on the fingerprint images, It is a morphological process that is adapted to erase the foreground pixels from the binary pictures.
-The second step is *Features extraction* step of the system which is a minutia extraction is performed by using the eight-neighbor technique. This technique is better than the other methods because of the efficiency of its computation and its simplicity. This method involves thinning image utilizing where the ridge flow has connected at eight points. The minutiae pixels are extracted by using a 3X3 window by scanning the local region of every Pixel in the image.
-The third step is *Fingerprint Identification* , which clarifies in the following steps:

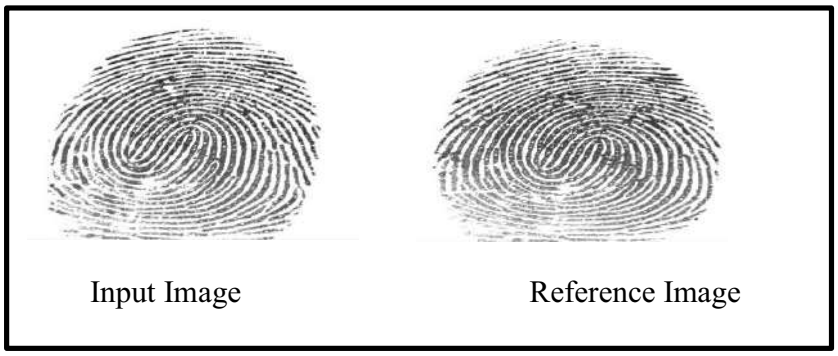
- The matching images are blocked into 8-blocks.
- Each minutiae in the input image are matched with all the minutiae that lying in the same block of the image of the reference image.
- To determine the similarity between minutiae , the matching step is performed by using the direction of line between the minutiae pixel and its neighbor pixel by using the equation (1).The direction should be equal in the matched minutiae object.

$$\Phi = \tan^{-1}\left(\frac{ym-y}{xm-x}\right) \quad \ldots (1)$$

Where,
(xm, ym) the coordinate of minutiae pixel
(x,y) the coordinate of its neighbor.

4. The Outcomes with the Discussion

The proposed system applied on a fingerprint dataset that download from ***Neurotechnology*** company website. It was founded in Vilnius, Lithuania in 1990 with the key idea of using neural networks for applications such as biometric person identification, computer vision, robotics and artificial intelligence.
The following results is for input and reference images which are illustrated in figure-2.
The results of the first step of the proposed system can be showing in the figure-3.



Figur-2 Input and Reference Images

Figure-3 Preprocessing Stage Results

The results of second stage for input image and the reference image are illustrated in table-1.

Tabel-1 Minutiae Feature vectors

Reference image	Input Image
(193,385)	(46,259)
(226,353)	(101,299)
(237,154)	(200,106)
(252,282)	(215,383)
(267,377)	(226,318)
(269,258)	(238,338)
(302,373)	(272,272)
(331,413)	(272,299)
(339,376)	(282,305)
(368,388)	(64,313)
(93,308)	(71,164)
(122,428)	(80,177)
(148,344)	(91,272)
(175,355)	(138,58)
(211,263)	(167,372)
(252,266)	(235,58))
(291,115)	(251,191)
(342,241)	(255,295)
(365,352)	

The results of final stage of the system are calculate the direction of angles for the minutiae points of the input and reference images according equation-1 and return the identification if performed between the two images.

5. Conclusion

After applying the proposed system, we got the result that either the two images belong to the same person or not. The system gave a higher rate of matching when the two images belong to the same person. It also gives a lower rate when the two images belong to different persons.

Anatomical and chemical study on the growing Eriobotrya japonica in Anbar Governorate

Anatomical and chemical study on the growing Eriobotrya japonica in Anbar Governorate

Lubab Mohamed Awad [1] and Ashwaq Talib Hameed [2]

[1,2] Biology Department, College of Education for Women, University Of Anbar, Iraq.

lubab.awad@uoanbar.edu.iq Ashwaq.Talib@uoanbar.edu.iq

Abstract. current research consists of an anatomical find out about of the Eriobotrya japonica from the Rosaceae in Anbar Governorate, which is in the structure of planted trees. The anatomical features of the s, leaf blade and market have been studied and its traits and floor have taxonomic significance in keeping apart and diagnosing this type. Appearance qualities can be linked with anatomical qualities to achieve an built-in classification. The quantity of layers and thickness of every organ, vascular bundles characteristics, wide variety of vessels, the traits of epidermal cells and cross-section structure are all studied contributing to taxonomic significance . The current study also dealt with the phenotypic characteristics of the stem, leaf and stalk, and it became clear through this study that the stems of the type Eriobotrya japonica were cylindrical and hard with many branches and were distinguished by a greenish-brown color. It is not a fixed characteristic of the single type in addition to the shape of the leaf, which is one of the important features in the classification. The stalk is characterized by being short and covered with hairy and green or yellowish green color, and these characteristics are important in the classification of this type. The fatty acids were detected in the hexane extract of Eriobotrya japonica in the gas chromatography device - GC, and the results indicated that this type contains fatty acids, the highest percentage of linoleic acid was 60% and the lowest Linolenic acid by 0.17%.

1. Introduction

The Rosacea household is one of the good sized botanical households with about 3000 species and one hundred genera [1]. It is one of the households noted in the Iraqi Flora of Iraq and it consists of one hundred forty genus and this household is unfold in the areas of the world and has been assigned a classification key in Iraq incorporates eleven . species and is in the structure of trees, shrubs, and herbs. [2 , 3] cited that there are 19 species and forty three species that are both wild or cultivated. [4] it carries one hundred fifteen species and 3200 species unfold in North America, East Asia, and Europe and there are 19 species and 50 species in Iraq. Eriobotrya japonica, an evergreen tree

belonging to the Maloideae of Rosaceae that consists of about 940 species .[5] Its size is 10m and perhaps the smallest in size between (3- 4) m.[6] This plant has medicinal and dietary significance as used in the remedy of many et al illnesses. [7] And It is a supply of dietary phenols. [8] It is additionally an decorative tree and an essential supply of nectar for beekeeping .[9] It has been cultivated for extra than 2000 years and is now cultivated commercially in 30 nations [10] The leaf

frequently reaches 30 cm in width and 9 cm in width in which the top floor is smooth and the decrease one consists of fluff [11] The anatomical find out about is vital in the classification of species, ranks, and households .[12] and additionally has extra interest in figuring out the genetic

2. Materials & Methods

2.1. Collection of samples:

This find out about relied on the smooth samples of the plant Eriobotrya japonica, which had been gathered from the Heet areas of Anbar Governorate in the duration from June 2019 to March 2020. The components that are wholesome have been.

relationships between species and taxonomic degrees .[13] The anatomical learn about helped in resolving matters The troubles encountered by way of the researcher or classifier in the match of overlap or similarity in phenotypic traits .[14] The purpose of this find out about was once to provide an anatomical photograph to some vegetative components such as the leaf, stem, and the market for the plant Eriobotrya japonica, which are nearly non-study in Iraq, as properly as the lack of lookup and sources That research the anatomical aspect in Iraq and the world.

besides ailments and rupture. A pattern of the plant was once taken and was once recognized the usage of the supervisor and relied on the classification keys referred to in the Iraqi flora [14] .

2.2. Anatomical study:

Prepare permanent vertical sections of the organs slides of the stem , leaf and petiole, The wax method mentioned was used [8].

3. Results and discussion

3.1. The section of leaf lamina

The modern-day find out about of the kind Eriobotrya japonica proven in Table No. 1 and determine 1 confirmed that it consists of easy dermis consisting of Uniseriate rectangular cells in which the higher epidermal cells regarded large than the decrease dermis and the common epidermal thickness was once 15 Mm, whilst the common thickness of the decrease dermis reached 19 Mm, it grew to be clear that the Mesophyll tissue in this kind was once Unifacial, which means that the palisade layer is positioned simply beneath the higher pores and skin and is aligned to one floor and then the spongy layer [12] mesophyll consists two layers layer of palisade is the type that follows the top pores and skin and the quantity of ranks (4- 2) and are cells compact and common thickness reached 92 The 2d layer is spongy layer used to be had 5-4 ranks, which reached a thickness charge 100 Mm which is characterised through free and disjoined cells and there are between interfaces distances cells and types are irregular and both the center vicinity of race grew to become out to be made up of parenchyma tissue that characterised their cells as are the dimension of there is a area between them and incorporates prolonged and giant vascular bundles.

Each bundle consists of xylem and Phloem wood. The common thickness of the wooden is sixty four and the thickness of the bark 33. The quantity of rows of vascular devices in the center vein 35-22 and the diameter of the vascular bundles 401Mm, this learn about coincided with . [14] the anatomical learn about gave many vital elements that helped aid the phenotypic traits used in classification and additionally this find out about helped to isolate this kind by way of identifying the traits of the Mesophyll tissue of the leaf and additionally by means of the quantity of layers of the tissue and additionally this kind can be remoted thru The variety of vascular devices in the vascular bundle of the leaf

3.2. Surface coating Idumentum

The results of the Eriobotrya japonica shown in fig. (4) it contains trichomes that differed in their dimensions and distribution according to the different plant members, which are of the Eglandular and unicellular trichomes with a cylindrical shape and end as pointed or rounded and found on leaves and stem And the petioles these results were in agreement with [9].

3.3. The section of Stem

The modern-day learn about of the stem of the kind Eriobotrya japonica, proven in Table (2) fig. (2). the stem in this kind used to be circular, Solid and Pith occupies the center, the area used to be displaying the center of the stem, in general, incorporates an exterior layer known as Cuticle surrounding In the pores and skin from the outside, its cells are uneven with an common thickness of 6 Mm, and then the dermis layer comes in. The cells are nearly rectangular, fairly small, and consist of one layer, and they are continuous. After the dermis layer comes to the cortex, which consists of multilayers in which the cells are various and the common thickness is 517. The first layer in the Eriobotrya japonica consists of the Collenchyma tissue, and this is observed via the Parenchyma tissue. The thickness of the Collenchyma tissue 105. Its thickness (178). As for the vascular cylinder, it grew to become clear that it is a non-stop annular cylinder round the circumference of the stem that is parallel to the Cortex. The vascular cylinder consists of xylem wood (sixty eight) Mm and the Phloem bark, 17 Micrometers. The pith is placed in the core of the stem, and it consists of large-sized, large-scale parenchyma cells[12]. The partitions are thin, stored, and formed in a round polygon. The thickness of the pulp in this kind reached 494 Mm. Through the anatomical facets of the vascular cylinder the place they have been of the non-stop kind and information of the houses of the vascular bundles and the thickness of every layer in the stem have a classification fee in setting apart and diagnosing the type.

3.4. Leaf petiole Section

The cutting-edge learn about of the Eriobotrya japonica petiole market confirmed its facts in Table three and fig. (3), the cross-section from the center of the organ is a part from the backside a little sharp and from the pinnacle convex there is a cuticle from the backyard and has a thickness of 3 Mm and surrounds the pores and skin consisting of one row of The cells are nearly cubic in form and include the bases of hairs and their thickness is 15 (after the epidermis). The layer of the cortex is made up of two sorts of tissues. The first layer consists of non-stop Columbia tissue with an common thickness of 158Mm and the tissue that comes after it is the Parenchyma tissue whose thickness used to be 226Mm. As for the vascular bundles in this type, they are open and the wide variety of bundles in them is 3 mid-site bundles and two lateral bundles. The wide variety of rows of vascular gadgets (6-8) and the variety of vascular gadgets per row (5-2). The cross-section of the Eriobotrya japonica market had an necessary classification value, as nicely as the structure of the vascular bundle that was once open and the separated bundles and their number, are three bundles one of them is the web page intermediate and two facet bundles and the size of the bundle are

remoted and additionally the collenchyma tissue of the cortex in this kind used to be of the angular collenchyma kind and the thickness of these layers [13]. All qualities have a taxonomic fee in isolation and prognosis of the species. Through this find out about and know-how of the anatomical traits, these features that have been recognized in this learn about can be localized in isolation of the kind and additionally can hyperlink between the anatomical and phenotypic features the place between the researcher [14] for the duration of his announcing it is feasible to acquire an built-in herbal and best classification solely when linking the anatomical data with Observations stemming from phenotypic studies, and this is what used to be emphasised in this learn about and the opportunity of making anatomical records got to serve the plant classification[15].

Table 1. shows the dimensions of the leaf blade of *Eriobotrya japonica* measured

Cuticle thickness	Epidermis thickness		Mesophyll			Vein

3.5. Morphological study

Stems & Twig legs and branches

The current study revealed that the stems of the type Eriobotrya japonica are cylindrical in shape, solid, and have many erect branches. The quality of the leg is shown in Table (4).

Table 4. Shows the quantitative and qualitative characteristics of the stem for the species *Eriobotrya japonica*

Plant height	Nature of plant	Nature of stem	Branches	Branching type	Branching color
(2-8)m	Trees	Erect	Many	Upper	Green brown

3.6. *Leaves*.

The leaves are one of the basic physiological axes of the plant as it performs important processes such as photosynthesis and transpiration as it works alongside other plant devices such as wood and bark and contributes to the absorption of nutrients and water from the soil through the roots and allows the transfer of metabolic products from them to the rest of the plant body. Eriobotrya japonica leaves are distinguished. It is simple, petiolate, and alternate, and it should be noted that the leaves from the vegetative parts that are more susceptible to environmental conditions and the characteristics that are most exposed to variations are the dimensions of the leaf, then followed by the shape of the blade, its base, its edge and finally the color of the leaf. In this study the shape of the blade was fixed and the table (5) It shows the quantitative characteristics of the leaves of the type[16]. The dimensions of the paper were different in terms of length and width, where the average length of the blade was (260) mm and the average width was (90) mm. The upper, open color in the lower surface, and the shapes and structure of the blades have basic features and have an important role in classification. Acute is sharp, while the edge of the leaf in Eriobotrya japonica is serrated, and the edge of the blade is one of the most important characteristics that distinguish the leaves, in addition to its shape. The edge of the blade gave a taxonomic weight no matter what it is not a fixed characteristic for individuals of the same species. As for the leaf base, it was rounded. It was identical to the plant wealth in Iraq [17]. As for the surface covering of the leaves, it was almost smooth on the upper surface and had dense fluffy filaments on the lower surface.

Table 5. Shows the dimensions of the leaf blade for the *type Eriobotrya japonica* measured in MM.

Blade length	Blade width	Average blade length\ Average blade width

(130-390)260	(50-130)90	2.9

3.7. Petiole

The study of the type Eriobotrya japonica showed that the stem is circular in the cross section, but it showed variations in its dimensions, as the stems of this type were short and covered with a capillary covering and the color of the stalk is green or yellowish green. The width of the stem is (5) mm, and the average length of the stalk to the average of the stem width is (2.6) mm

Table 6. Shows the dimensions of the petiole for the type Eriobotrya japonica measured in MM.

Petiole length	Petiole width	Average petiole length\Average petiole width
(7-19)13	(3-6)5	2.6

Table 7. The fatty acid present in Eriobotrya japonica extract By GC

Fatty acid	Concentration %
Palmitic acid	5.10
Palmitoleic acid	1.74
stearic	3.18
Oleic acid	4.45
Linoleic acid	60.0
Linolenic acid	0.17

The results of the extract of Eriobotrya japonica in the gas chromatography device - GC showed that the plant contains several types of fatty acids, where the highest percentage of linoleic acid was 60%. Table (4) Unsaturated fatty acids are important compounds for metabolic processes inside the body of the organism, as Linoleic acid helped expand the respiratory tracts and build red blood cells, and its deficiency leads to high cholesterol in the blood and liver and leads to stunted growth in children [11] Also, fatty acids are anti-inflammatory and prevent type 2 diabetes and prevent high blood pressure [12].

Abstract : Let R be a commutative ring with an identity , and G be a unitary left R-module . A proper submodule H of an R- module G is called semiprime if whenever $a \in R, y \in G, n \in Z^+$ and $a^n y \in H$, then $ay \in H$. We say that a proper submodule H of an R- module G is a weakly small semiprime, if whenever $a \in R, y \in G, n \in Z^+$, (y) is small in G and $0 \neq a^n y \in H$, implies $ay \in H$. Many basic properties and characterizations of this type of submodule are given.

Keywords : semiprime submodules , semiprime modules , small semiprime submodule , small semiprime modules .

1.Introduction

In this research we introduce the concept of weakly small semiprime submodule as a generalization of small semiprime submodule and established some of its basic properties , examples and characterizations. A proper submodule H of an R - module G is called a small semiprime submodule if $for\ each\ r \in R$, $x \in G$, $n \in Z^+$ and $x \in G$ such that $r^n x \in H$ implies $rx \in H$, [6] . A proper submodule H of an R - module G is called a small semiprime submodule if $for\ each\ r \in R$, $x \in G$, $n \in Z^+ with\ (x) \ll G\ such\ that\ r^n x \in H\ implies\ rx \in H$. A proper ideal I of a ring R is called small semiprime ideal if whenever $0 \neq a^k b \in I$ for $a , b \in R$, $k \in Z^+$ and $(b) \ll R$ implies $ab \in I$, [5] . Where "a submodule P of G is called small (notationally , $P \ll G$) if $P + W = G$ for all submodules W of G implies $W = G$", [3]. Let G be an R- module a proper submodule H of G is called weakly small semiprime , if whenever $0 \neq r^k x \in H$ for some $r \in R$ and $(x) \ll G, k \in Z^+$ implies $rx \in H$.

In section 1 we study some basic properties for the concept of a weakly small semiprime submodule. In section 2 we give properties of weakly small semiprime submodule in class of multiplication and hollow R- modules.

2.Weakly Small Semiprime Submodules

In this section we introduce the concept of weakly small semiprime submodule as a generalization of small semiprime submodule and established some of its basic properties, examples and characterizations.

Recall that a proper submodule H of an R - module G is called a weakly semiprime submodule if $for\ each\ r \in R$, $x \in G$ and $n \in Z^+$ such that $0 \neq r^n x \in H\ implies\ rx \in H$, [2].

Definition (2.1)

Let G be an R- module a proper submodule H of G is called weakly small semiprime If whenever $0 \neq r^k x \in H$ for some $r \in R$ and $(x) \ll G, k \in Z^+$ implies $rx \in H$.

A proper ideal I of a ring R is called weakly small semiprime ideal if whenever $0 \neq a^k b \in I$ for $a, b \in R$ and $k \in Z^+$ and $(b) \ll R$ implies $ab \in I$.

Remark (2. 2)

It is clear that every small semiprime submodule is weakly small semiprimei submodule. But the converse is not true in general, as the following example show:

Example (2. 3)

Let $G = Z_{24}$ as a Z- module , $H = (\bar{8}) = \{\bar{0}, \bar{8}, \overline{16}\}$, H is a proper submodule of Z_{24} .Then $\forall r \in Z, x \in G$, k $\in Z^+$ *and* $(x) \ll G$ such that $0 \neq r^k x \in B$ implies $rm \in H$, so H is weakly small semiprime submodule . But H is not small semiprime submodule since $\bar{0} = 4.\bar{6} = 2^2.\bar{6} \in H$ and $(\bar{6}) \ll Z_{24}$ But $\overline{12} = 2.\bar{6} \notin H$.

Recal lthat if R is an integral domain and G is an R – module ,Then $T(G) = \{x \in G : rx = 0 \ for\ some \ \ 0 \neq r \in R\}$ is a submodule of G . If $(G) = 0$, Then we say that G is torsion – free R- module .

Now we can say , If R is an integral domain and G is an R – module ,Then $Ts(G) = \{x \in G : rx = 0 \ and \ (x) \ll G \ \ for\ some \ \ 0 \neq r \in R\}$ is a submodule of G . If $s(G) = 0$, Then we say that G is small torsion – free R- module .

proposition (2. 4)

Let R be on integral domain and let G be a small torsion free R – module . Then every weakly small semiprime submodule of G is a small semiprime submodule of .

Proof :

Let H be a weakly small semiprime submodule of . Let $r \in R, x \in G$ and $(x) \ll G, k \in Z^+$ such thet $r^k x \in H$ to show that $x \in H$. If $0 \neq r^k m$, then $rx \in H$. Suppose that $r^k x = 0$, since R integral domain implies

If $r^k \neq 0$, then $x \in Ts(G) = 0$ hence $rx \in H$.

If $r^k = 0$, then $r = 0$ hence $rm \in H$. Therefore H is small semiprime submodule of M.

Recall that a proper submodule H of an R - module G is called a small prime submodule if and only if whenever $r \in R \ and \ x \in G$ with $(x) \ll G$ and $rx \in H$ implies either $r \in H \ or \ r \in [H : G]$ and an R – module G is called a small prime iff (0) is a small semiprime submodule of M , [6] .

proposition (2. 5)

Let G be a small prime R - module . Then every weakly small semiprime submodule of G is small semiprime submodule of .

Proof :

Let H be a weakly small semiprime submodule of . Let $r \in R, x \in G$ and $(x) \ll G, k \in Z^+$ such that $r^k x \in H$. If $0 \neq r^k x$, since H is weakly small semiprim submodule of G , then $rx \in H$.

Suppose $r^k x = 0$, then $rx = 0$ *or* $r^{k-1} = 0$ since (0) is small prime submodule of G (G is a small prime R – module) , so $rx = 0 \in H$, hence H is small semiprime submodule of G .

Theorem (2. 6)

Let G be an R- module and let H be a proper submodule of G . Then the following statements are equivalent :

1. H is weakly small semiprime submodule of G .

2. For each $r \in R$, $x \in G$ and $(x) \ll G$, $k \in Z^+$, $\left[H :_G (r^k)\right] = \left[0 :_G (r^k)\right] \cup [H :_G (r)]$.

3. For each $r \in R$, $x \in G$ and $(x) \ll G$, $k \in Z^+$, $\left[H :_G (r^k)\right] = \left[0 :_G (r^k)\right]$ or $\left[H :_G (r^k)\right] = [H :_G (r)]$.

Proof:

(1) $\Longrightarrow$(2) Let $x \in \left[H :_G (r^k)\right]$, $(x) \ll G$, then $r^k x \in H$.

If $r^k x \neq 0$, since H is weakly small semiprime submodule of G . $rx \in B$. so $\in [H :_G (r)]$. Let $r^k x = 0$, $(x) \ll G$ then $x \in \left[0 :_G (r^k)\right]$ and hence

$\left[H :_G (r^k)\right] \subseteq [H :_G (r)] \cup \left[0 :_G (r^k)\right]$ clearly $[H :_G (r)] \cup \left[0 :_G (r^k)\right] \subseteq$

$\left[H :_G (r^k)\right]$ ther efore $\left[H :_G (r^k)\right] = [H :_G (r)] \cup \left[0 :_G (r^k)\right]$.

(2) $\Longrightarrow$ (3) It is clear .

(3) $\Longrightarrow$(1) Let $0 \neq r^k x \in H$ for some $r \in R$, $x \in G$ and $(x) \ll G$, $k \in Z^+$. Hence $x \in \left[H :_G (r^k)\right]$ and $x \notin \left[0 :_G (r^k)\right]$ so by assumption $x \in \left[H :_G (r)\right]$ i.e $rx \in H$. Therefore H is weakly small semiprime submodule of .

Theorem (2. 7)

Let G be an R- module and let A be a proper submodule of G . Then A is a weakly small semiprime submodule of G if and only if for any small submodule H of , $r \in R$, and $k \in Z^+$ with $0 \neq (r)^k H \subseteq A$ *implies* $(r)H \subseteq$ A .

Proof:

($\Longrightarrow$) Suppose that $0 \neq (r)^k H \subseteq$ A for $r \in R$ and H is a small Submodule of G and $k \in Z^+$, so $0 \neq (r^k)H \subseteq A$ *implies* that $H \subseteq [A :_G (r^n)]$ with $H \nsubseteq [(0) :_G (r^n)]$ Theorem (2.6) implies $H \subseteq [A :_M (r)]$ heace $(r)H \subseteq$ A .

($\Longleftarrow$) Let $0 \neq r^n x \in A$ for $r \in R$, $(x) \in G$ and $n \in Z^+$ implies that $0 \neq (r^n)(x) \subseteq$ A So by hypothesis $(r)(x) \subseteq A$ implies that $rx \in A$. Then A is a weekly small semiprime submodule of .

Corollary (2. 8)

Let G be a R- module and A be a proper submodule of G . Then A a weakly small semiprime submodule of G if and only if $0 \neq (r)^k G \subseteq A$ for $r \in R$, H is small submodule of G and $n \in Z^+$ implies that $(r)G \subseteq A$.

Corollary (2. 9)

Let A be a proper submodule of an R- module G. Then A is a weakly small semiprime submodule of G if and only if $0 \neq r^k H \subseteq A$ for $r \in R$, H is small submodule of G and $k \in Z^+$ implies that $rH \in A$.

Recall that if H is a semiprime submodule of an R- module G, then $[H : G]$ is a semiprime ideal of R. For weakly small semiprime we have:

Remark (2. 10)

If H is a weakly small semiprime submodule of an R – module G, then $[H : G]$ need not be weakly small semiprime in general .

For example : Let $G = Z_8$ as a Z – module . Take$H = \{\bar{0}\}$ clearly H is a weakly small semiprime submodule of G, but $[H : G] = 8Z$ is not weakly small semiprime ideal of Z .

Theorem (2.11)

Let H be a submodule of an R – module G with $T_S(G) = 0$. H is a weakly small semiprime submodule of G if and only if for non-zero ideal I of , $\left[H \vdots_G I\right]$ is a weakly small semiprime submodule of G .

Proof:

($\Longrightarrow$) Let $r \in R$, $x \in G$ and $(x) \ll G$, $k \in Z^+$ such thet $0 \neq r^k x \in \left[H \vdots_G I\right]$ hence $(r)^k(xI) \subseteq H$. If $0 \neq (r)^k(xI) \subseteq H$, $(xI) \ll G$, [1] . H is a weakly small semiprime submodule of G , implies that $(r)\,(xI) \in N$ by Theorem (2.6) so $r \in \left[H \vdots_G I\right]$ as needed suppose that $(r)^k(xI) = 0$ so $r^k xa = 0$ for some non-zero $a \in I$. Hence $r^k x \in T_S(G) = 0$ which is a controdition . Therefore $\left[H \vdots_G I\right]$ is a weakly small semiprime submodule of G

($\Longleftarrow$) Suppose that $[H \vdots_G I]$ is a weakly small semiprime submodule of G. For any non-zero ideal I of , put $I = R$ we get $[H \vdots_G I] = A$ which is weakly small semiprim submodule of *M*

Remark (2.12)

In the Theorem (2.11). The assumption $T_S(G) = 0$ is necessary .

To show that , let $G = Z_{16}$ as a Z - module , $H = \{\bar{0}\}$ and $I = 2Z$. Clearly H is a small semiprime submodule of G, hence H is a weakly small semiprime submodule of G by Remark (2.2) , but $[H \vdots_G I] = \{\bar{0}, \bar{8}\}$ is not weakly small semiprime submodule of G , since $(\bar{2}) \ll Z_{16}$ and $4 . \bar{2} \in \{\bar{0}, \bar{8}\}$ but $2 . \bar{2} \notin \{\bar{0}, \bar{8}\}$.

proposition (2.13)

Let G be a R- module and H, C be submodule of G with $C \nsubseteq H$ **.** If B is a weakly small semiprime submodule of G . Then $H \cap C$ is a weakly small semiprime submodule of .

Proof:

It is clear that $H \cap C$ is a proper submodule of . Let $0 \neq r^n x \in H \cap C$ for $r \in R$, $x \in C$ and $(x) \ll C$, $n \in Z^+$ it follows that $0 \neq r^n x \in H$. $(x) \ll G$ implies $(x) \subseteq Rad\,(C) \subseteq Rad\,(G)$, $then$ $(x) \subseteq Rad\,(C)$, since H is weakly small semiprime submodule of G , then $rx \in H$ and $x \in C$, $rx \in C$, hence $rx \in H \cap C$ and $H \cap C$ is a weakly small semiprime submodule of C .

proposition (2.14)

Let $G = G_1 \oplus G_2$ be an R- module where G_1, G_2 are R- modules such that $annG_1 + ann\,G_2 = R$. If A_1 is a weakly small semiprime submodule of G_1 , then $A_1 \oplus G_2$ is a weakly small semiprime submodule of G .

Proof:

Let $0 \neq H \ll G_1 \oplus G_2$, $r \in R$ and $n \in Z^+$ such thet $(r)^n H \subseteq A_1 \oplus G_2$. To show that $(r)H \subseteq A_1$ since $annG_1 + ann\, G_2 = R$, then $H = H_1 \oplus H_2$ where $H_1 \subseteq G_1$ and $H_2 \subseteq G_2$, $H \ll G$ implies $H_1 \ll G_1$ and $H_2 \ll G_2$ [1] .

$0 \neq (r)^n (H_1 \oplus H_2) \subseteq A_1 \oplus G_2$ $r^n H_1 \oplus H_2 \subseteq A_1 \oplus G_2$, so $(r)^n H_1 \subseteq A_1$ since A_1 is a weakly small semiprime submodule of G_1 and $H_1 \ll G_1$, then $(r)H_1 \subseteq A_1$ by Theorem (2.7) . Hence $(r)H \subseteq A_1 \oplus G_2$, which implies that $A_1 \oplus G_2$ is a weakly small semiprime submodule of .

proposition (2.15)

Let $G = G_1 \oplus G_2$ be an R- module where G_1, G_2 are R- modules and $A = A_1 \oplus A_2$ be a submodule of G . If A is a weakly small semiprime submodule of G .Then A_1, A_2 are weakly small semiprime submodules of G_1, G_2 respectively .

Proof :

Let $0 \neq H_1 \ll H_1 \oplus G_1$, $r \in R$ and $n \in Z^+$ such that $0 \neq (r)^n H_1 \subseteq A_1$. To show that $(r)H_1 \subseteq A_1$. $(r)^n H_1 \oplus 0 \subseteq A_1 \oplus A_2 = A$, then $(r)^n (H_1 \oplus 0) \subseteq A$. But $H_1 \ll G_1$, so $(H_1 \oplus 0) \ll G_1 \oplus G_2 = G$, [1] . Since $A = A_1 \oplus A_2$ is a weakly small semiprime submodule of G and $(H_1 \oplus 0) \ll G = G_1 \oplus G_2$ implies $(r)\ (H_1 \oplus 0) \subseteq A = A_1 \oplus A_2$, hence $(r)\ H_1 \oplus 0 \subseteq A_1 \oplus A_2$. It follows that $(r)H_1 \subseteq A_1$. Hence A_1 is a weakly small semiprime submodule of G_1 . Similary we can prove that is a weakly small semiprime submodule of G_2 .

3.Weakly Small Semiprimei Modules and Special Kind of Modules.

This section is to give properties of weakly small semiprime submodules in class of multiplication R-module, faithful R-module and hollow R-modules.

proposition (3.1)

Let G be a faithful **f . g**. multiplication R- module and let H be a weakly small semiprime submodule of G . Then $[H : G]$ is a weakly small semiprime ideal of .

Proof:

Let H be a weakly small semiprim submodule of G , $a, b \in R$, $(b) \ll R$, and $k \in Z^+$ such that $0 \neq a^k b \in [H : G]$,then $0 \neq (a)^k (bG) \subseteq H$. $(b) \ll R$ implies $(b\, G) \ll G$ [1] , if $(a)^k (bG) = 0$. Then $a^k b \in [0 : G] = 0$ contradiction . Now Theorem (2.7) implies that $(a)(bG) \subseteq H$ so $ab \in [H : G]$ and $[H : G]$ is a weakly small semiprime ideal of .

Theorem (3.2)

Let G be a f . g. faithful multiplication R- module and let H be a proper submodule of M .Then the following are equivalent .

1. H is a weakly small semiprime submodule in$G$.
2. $[H :_R G]$ is a weakly small semiprime submodule in R
3. $H = JG$ for some weakly small semiprime ideal J of .

Proof:

$1 \Longrightarrow 2$ Let $0 \neq r^k s \in [H :_R G]$ for $r \in R$, and $k \in Z^+$, s is a non -zero element of R and $(s) \ll R$. It follows that $0 \neq r^k s \subseteq H$, $(s) \ll R$, M is f.g multiplication implies $(sG) \ll G$, since B a weakly small

semiprime submodule in G , then $rsG \subseteq H$, hence $rs \in [H :_R G]$ that is $[H :_R G]$ is weakly small semiprime ideal of R .

$2 \Longrightarrow 3$ We choose $J = [H : G]$.

$3 \Longrightarrow 1$ Since G multiplication module , Let $0 \neq r^k x \in H$ where $r \in R$, $x \in G$ and $(x) \ll G$, $k \in Z^+$ Then $(r)^k [(x) : G] \subseteq [(r^k x) : G] \subseteq [H : G]$. Moreover $(r^k)[(x) : G] \neq 0$ because otherwise .

If $(r)^k [(x) : G] = 0$ Then $(r)^k (x) = (r)^k [(x) : G]G = 0$ as $[H : G]$ is a weakly small semiprime ideal of R contradiction . $(r) [(x): G] \subseteq [H : G]$

therefore $(r)(x) = (r)[(x): G]G \subseteq [(x): G]G = B$ and so $rm \in H$ implies H a weakly small semiprime submodule in G .

Recall that an R- module G is a called hollow module if every proper submodule A of G is small , that is if $G = A + H$ for some submodule H of G implies that $H = G$.

Recall that if G is an R- module , then $Rad(G)$ is the intersection of all maximal submodule of G , $Rad(G)$ is called the Jacobson radical of G , [4] . If A is a submodule of an R- module G with $Rad(\frac{G}{A}) = (0)$, then $Rad(G) \subseteq A$, [3] .

proposition (3.3)

Let G be an R- module with every cyclic submodule is small . If H is weakly small semiprime submodule of , then H is weakly semiprime of G .

Proof:

Let $0 \neq r^k x \in H$ for $r \in R$, $x \in G$ and $n \in Z^+$. Since every cyclic submodule of G is small , then $(x) \ll G$. But H is weakly small semiprime , it follows that $rx \in H$. Hence H is weakly semiprime submodule of .

Corollary (3.4)

If G is a hollow R- module , then every weakly small semiprime submodule of G is weakly semiprime .

proposition (3.5)

Let G be a R- module and H be a submodule of G . If $Rad(G)$ is a weakly small semiprime submodule of G with $Rad\left(\frac{G}{H}\right) = (0)$, Then H is a weakly small semiprime submodule of G .

Proof:

Let $0 \neq r^n x \in H$ for $r \in R$, $x \in G$ with $(x) \ll G$ and $n \in Z^+$. Since $(x) \ll G$, then $x \in Rad(G)$, [3] . Hence $0 \neq r^n x \in Rad(G)$. But $Rad(G)$ is a weakly small semiprim so $rx \in Rad(G)$. By assumption $Rad\left(\frac{G}{H}\right) = (0)$ implies $Rad(G) \subseteq H$, then $rx \in H$. Thus H is a weakly small semiprime submodule of G .

Lemma (3.6) [7]

Let G be a f . g. multiplication R- module and I , J are ideals of a ring R . Then $IG \subseteq JG$ if and only if $I \subseteq J + ann_R(G)$.

proposition (3.7)

Let G be a f . g. multiplication faithful R- module and I be a weakly small semiprime ideal of R with $ann_R(G) \subseteq I$. Then IG is a weakly small semiprime submodule of .

Proof:

Let $0 \neq r^n x \in IG$ for $r \in R, 0 \neq x \in G$ and $(x) \ll G$ and $n \in Z^+$ that $0 \neq r^n x \in IG$, since G multiplication , then $(x) = JG$ for som ideal J of R . That $0 \neq r^n x \in IG$ by lemme (3.6) $0 \neq r^n J \subseteq I + ann_R(G)$, but $ann_R(G) \subseteq I$ implies $ann_R(G) + I = I$ hence $0 \neq r^n J \subseteq I$, since $(x) \ll G, (x) = JG$ implies $(JG) \ll G$ but G is a f . g. multiplication implies $(J) \ll R$, since I is a weakly small semiprime submodule of R . It follows that $rJG \subseteq IG$ so $r(x) \subseteq JG$ implies JG is weakly small semiprime submodule of .

Corollary (3.8)

Let G be a faithful cyclic R- module and I be a weakly small semiprime ideal of R with $ann_R(G) \subseteq I$, then IG is a weakly small semiprime submodule of G .

Abstract. One of the important object detection applications in smart transportation systems is vehicle detection. Working on self-driving car robots has become an important experiment in recent years to take advantage of innovations and ideas in real self-driving cars, and the detection of robots by multiple algorithms is the most important phase in this work. To solve the problems of self-driving car robot detection. Such as not recognizing shape. In this paper, via the Yolov2 algorithm, we trained a new model for robots. It was proven with the comparison experiments that the proposed method is successful for robot detection. In addition, the proposed model demonstrated excellent feature extraction ability with network visualization.

1.Introduction

Computer vision is a tool for making machines "look". This allows computers and other devices to take the place of human eyes to recognize objects within the scene and further the processing of images. The new research trend for using artificial intelligence systems to extract data from images is image processing and computer vision. A significant branch of computer vision is object detection. object detection is Efficient when it is fast and accurate. Good object detection algorithms should be convenient for the lives of individuals. The purpose of this paper is to classify and locate self-driving car robots. It is important in the autonomous driving system to detect self-driving cars and their location. A self-driving car, also known as an autonomous vehicle (AV or auto), driverless car, or robot-car is a vehicle that is capable of sensing its environment and moving safely with little or no human input. Object detection is a very important part of artificial intelligence. Which is a forward-feedback neural network It has a unique superiority in object recognition with its special structure of local weights sharing. The interest in having deeper hidden layers has begun to surpass the performance of classical methods in various fields, particularly in pattern recognition. The Convolutional Neural Network is one of the most popular deep neural networks (CNN). It takes its name from the mathematical linear operation called convolution between matrixes. CNN has several layers [1], including the convolution layer, pooling layer and fully-connected layer. In machine learning issues, CNN has outstanding results. Especially those applications dealing with image data, The traditional detectors [3] first extract suggestions and extract features, then do the classification [2].it is proposed that location and classification in a single CNN be implemented. We want a real-time object detection algorithm in the self-driving system, so we chose you only look once (YOLO) as a guide to constructing a better method where More than twice the average accuracy of other real-time systems is reached by YOLO. To construct our own training set and testing set, we select some samples and label some samples manually. YOLO algorithm is an algorithm based on regression, instead of selecting the interesting part of an Image, it predicts classes and bounding boxes for the whole image in one run of the Algorithm [4]. The work discussed in this paper forms part of an automated monitoring system for vehicles. The main objective is to train a system to classify a new class Which self-driving cars robot define and monitor the behavior of autonomous robots. In this way, it is possible to track important events that took place on the way. The yolo detection system . Figure 1 shows how YOLO is refreshingly basic.

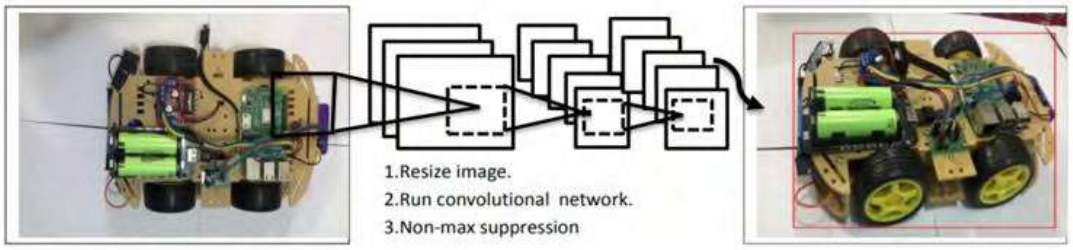

Figure 1. The YOLO Detection System

2. The proposed method

In Figure 2 Block diagram of the proposed system.

2.1. Data collection and prepare data

The images were collected by the iPhone 8 Plus camera, and the total number of images was 1235 the self-driving car robot, and since the system is under supervision depend on human work, Manual labeling for supervised learning, we use LabelImg to label images. LabelImg is available on mac, windows, and UNIX we do the labeling process to determine the Center X, y in the image, width, height and it belongs to any class. Within the process of pre-processing the data, missing labels for some image we removed them.

2.2. Yolo algorithm

YOLO divides the image in to S×S grids and predicts B bounding box and C class probability for each grid cell. Each bounding box consists of five predictions: w, h, x, y, and object confidence. The values of w and h represent the width and height of the box relative to the whole image. The values of (x, y) represent the center coordinates of the box relative to the bounds of the grid cell. The object confidence represents the reliability of existing object in the box to improve the YOLO prediction accuracy, Redmon et al. proposed a new version YOLOv2 in 2017. A new network structure Darknet-19 was designed by removing the full connection layers of the network, and batch normalization was applied to each layer. Referring to the anchor mechanism of Faster R-CNN, k-means clustering was used to obtain the anchor boxes. In addition, the predicted boxes were retrained with direct prediction. Compared with YOLO, YOLOv2 greatly improves the accuracy and speed of object detection. The Self-driving car robots dataset was divided into a training dataset and validation dataset with the ratio of 8:2, where the numbers of images in the training dataset 988 and numbers of images in the testing dataset 247. in this paper we used tensor flow lite keras [5]. TensorFlow [6] Lite is designed to run machine learning models with just a few kilobytes of memory on microcontrollers and other devices. The core runtime is only 16 KB and several basic models can be run. Keras is an API designed not for machines but for human beings. Keras follows good cognitive load reduction practices: it provides consistent and easy APIs, minimizes the number of user actions needed for common use cases, and provides simple and actionable error messages.An algorithm is a type of Supervised machine learning.

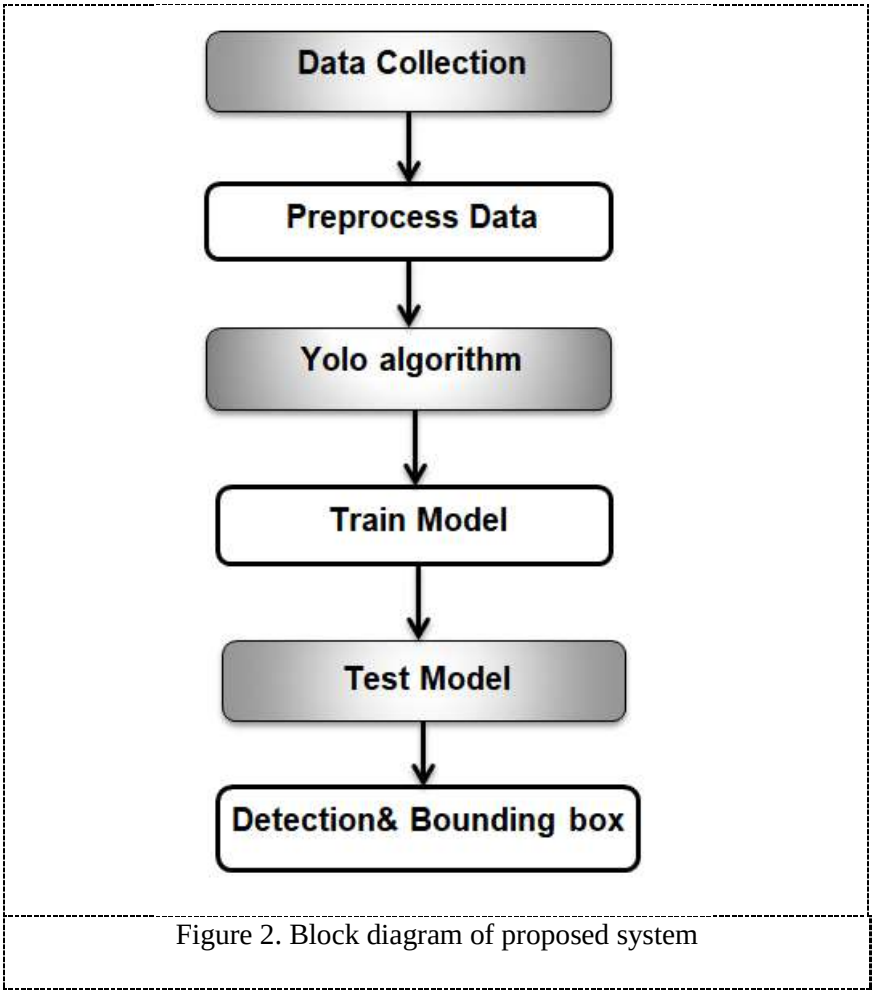

Figure 2. Block diagram of proposed system

2.2.1. Loss function

Different object sizes had different effects on the entire model when training YOLOv2, which resulted in greater errors for larger objects than for smaller objects. The loss estimate for the width and height of the bounding boxes was improved using normalization in order to reduce this effect. The enhanced loss feature is seen in Equation1 [9].

$$\lambda_{coord}\sum_{i=0}^{S^2}\sum_{j=0}^{B} I_{ij}^{obj}\left[(x_i-\hat{x}_i)^2+(y_i-\hat{y}_i)^2\right]$$
$$+\lambda_{coord}\sum_{i=0}^{S^2}\sum_{j=0}^{B} I_{ij}^{obj}\left[\left(\frac{w_i-\hat{w}_i}{w_i}\right)^2+\left(\frac{h_i-\hat{h}_i}{h_i}\right)^2\right]$$
$$+\sum_{i=0}^{S^2}\sum_{j=0}^{B} I_{ij}^{obj}\left(C_i-\hat{C}_i\right)^2$$
$$+\lambda_{noobj}\sum_{i=0}^{S^2}\sum_{j=0}^{B} I_{ij}^{noobj}\left(C_i-\hat{C}_i\right)^2$$
$$+\sum_{i=0}^{S^2} I_i^{obj}\sum_{c\in classes}\left(p_i(c)-\hat{p}_i(c)\right)^2$$

Where x_i and y_i are the center coordinates of the box .$\mathcal{W}_i$ and h_i are the width and height of the box .C_i is the confidence of the box of the i – the grid cell , and p_i (c) is the Class probability of the box of the i – the the grid cell . Furthermore , $\hat{x}_i$, $\hat{y}_i$, $\hat{w}_i$, $\hat{h}_i$, $\hat{c}_i$, and$\hat{p}_i$ (c) are the corresponding predictions of x_i , y_i, w_i , h_i , c_i , andp_i (c); λ_{coord} denotes the Weight of the coordinate loss, and λ_{noobj} denotes the weight of the bounding boxes without Objects loss, finally , s^2 denotes the $s \times s$ grid cells , B denotes the boxes , I_i^{obj} denotes Whether the object is located in cell i or not , and I_{ij}^{obj} denotes that the j – the box predictor in cell i is " responsible" for that prediction .

2.2.2. Model Architecture

The propose system detection network has 23 convolutional layers as shown in 3. The image size is 512 * 512. The images enter these layers and the features are extracted from them through the filters in each layer, where each layer has specific filters to extract the features starting from the lower level, middle level, and higher level. The edge might be detected in the first layers and then the simpler shapes in the second layers, and then the higher-level features such as Self-driving robot. The total of the filters in the first layer is (32) filters with dimensions of (3 * 3) and strides (1x1), and in order to preserve the shape of the image, the process padding is done by adding zeros around the image. After that cancel the bias and adding BatchNormalization to speed up the work. The type of activation function is Relu. Sigmoid and Tanh have been the most common non-linearity for several years. However, for the following reasons, the Rectified Linear Unit (ReLU) [1] has been used more commonly recently

1 - For both function and gradient, ReLU has simpler definition.

2 - The saturated function, like sigmoid and tanh, causes backpropagation problems. The gradient signal starts to disappear, which is called the "vanishing gradient" as the neural network architecture is deeper. This occurs because virtually anywhere but the middle, the gradient of those functions is very close to zero. The ReLU has a constant gradient for the positive input, however. Although the feature is not distinguishable, it can be overlooked in the actual implementation phase..

3 - A sparser representation produces the ReLU. The zero in the gradient leads to a complete zero being obtained. Sigmoid and tanh, however, still have non-zero gradient outcomes, which may not be in favor of training for training.

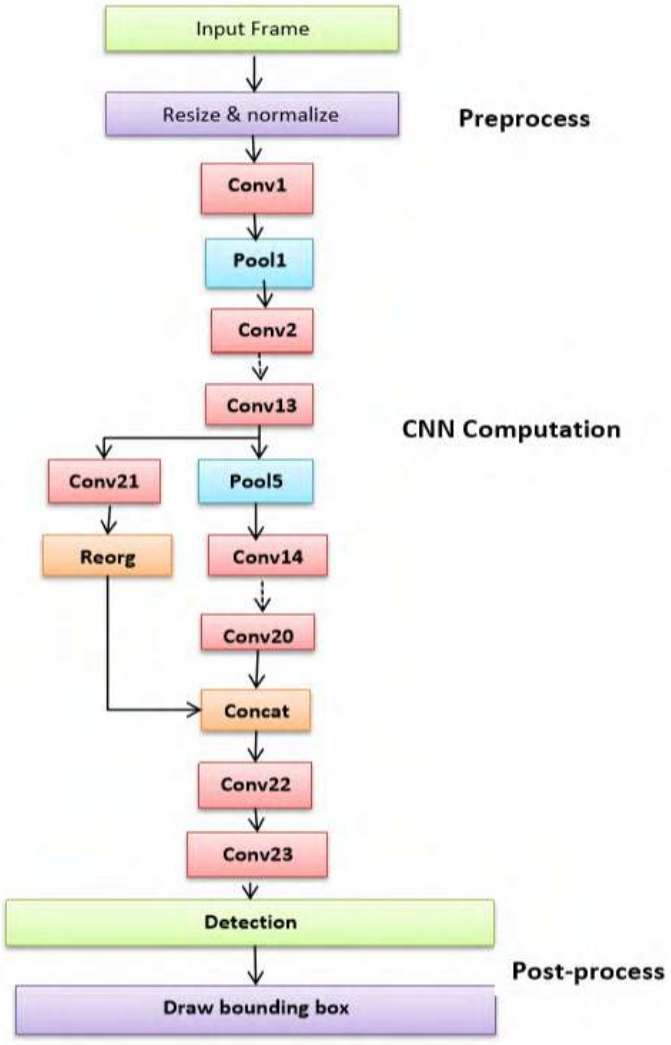

Figure 3. Layers of Yolov2 – self – driving car robot

Pooling : The main idea of pooling is to reduce samples to reduce complexity in layers. One of the most popular types of assembly is max-pooling, where you take an m* m patch and pass a filter over it that takes the largest value between the values. One of the most common sizes used in max-pooling is 2×2 [7-10]. As can see in Fig 4

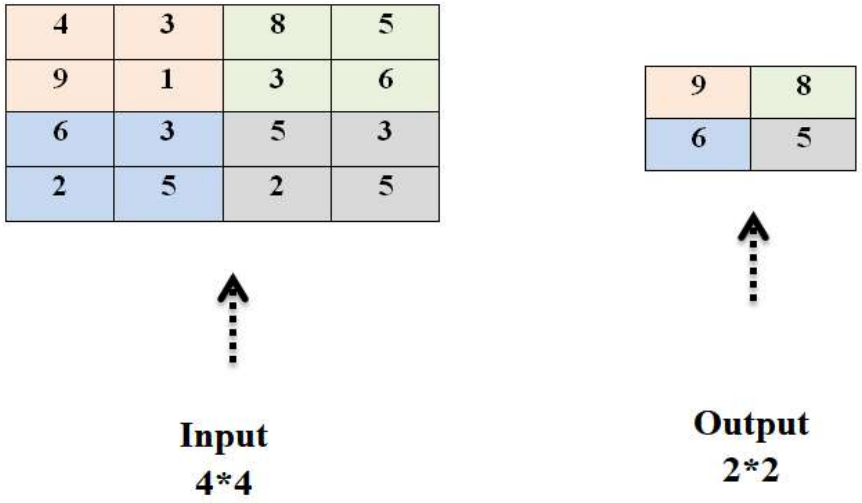

Figure 4:Max pool with 2*2 filters and stride 2

2.2.3 Non-max suppression

The objects in the image can be of various sizes and shapes, and to perfectly capture each of these, several border boxes are created by object detection algorithms. (Image on the left). Ideally, we must have a single bounding box for each object in the image. Something like that image to the right, To choose the best bounding box, From the multiple bounding boxes, predicted Non-max suppression is used in these object detection algorithms. This technique is used to "suppress" and hold only the best boxes that are less likely to be bound.

3.Implementation Results

In this paper, we have presented an algorithm for self-driving car robot detection and tracking and were score 82%, and a new class was called a self-driving car As in figure 5.
This class can be used in autonomous automobile robotics projects for autonomous vehicle path control or collision control. The first table shows the result after detection the class . The execution time of the object detection is real time. To calculate (F measure) we need Precision and Recall:

i. Precision measures how accurate your predictions are. i.e. the percentage of your predictions are correct.
ii. Recall measures how well you find all the positives

$$\text{F measure} = 2.\frac{\text{precision} \,.\, \text{recall}}{\text{precision} + \text{recall}}$$

$$\text{F measure} = \frac{\text{TP}}{\text{TP}+1/2(\text{FP}+\text{FN})}$$

$$\text{F measure} = \frac{202.54}{202.54+1/2(44.46)} = 0.90$$

Where TP Means number of true positives, FN mean number of false negatives.FP mean number of false positives.

The values taken in the equation are the set of test. In measuring object detection FP is sometimes canceled.

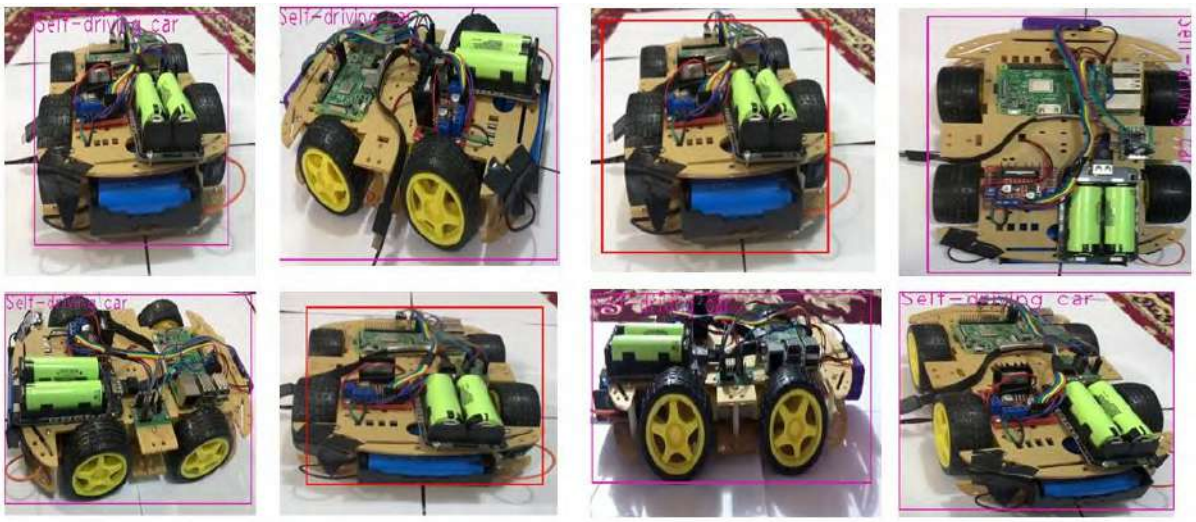

Figure 5. Detection results of YOLOv2_Self-driving car

4. Conclusion and Future Work

In this paper, a model called the YOLOv2_Self-driving car was proposed for vehicle detection by YOLOv2. The resulting system is both efficient and accurate based on the experimental results, the map of YOLOv2_ Self-driving car could reach 82%. Therefore, the proposed network is effective for Self-driving car robot detection. Although the model proposed in this paper achieved ideal experimental results, the number of images amounts of data is relatively low. In future work, we will collect more actual data to further study how to improve the accuracy and speed of Self-driving car detection.

Abstract-- In the current investigation, there was the use of the technology of machine vision. The usage of this technology was informed by the need to have the laser spot's highest energy positioned precisely, eventually allowing for the facilitation of further product work piece joining. Indeed, the joining occurred in laser welding machinery. Relative to the displacement phase, it is notable that it could aid in work piece placement into superposition areas, upon which there could be the joining of the parts. Training programs or models that were used involved convolutional neural network and deep learning, which allowed for the resultant system's enhancement of the accuracy with which the positioning could be achieved. Also, the aforementioned algorithms were insightful because they led to the enhancement of machine work efficiency. Similarly, in the study, there was the proposing of a bi-analytic deep learning localization technique. For the purpose of system monitoring in real time, there was the use of a camera. As such, the initial stage entailed the application of the convolutional neural network, which aided in the implementation of large-scale initial searchers before having the laser light spot zone located. In turn, the phase that followed entailed increasing the camera's optical magnification, which paved the way for the spot area's re-imaging, as well as the application of a template matching method to ensure that high-precision repositioning was achieved. When the parameter of the search result area's ratio was considered, it could be seen that the study was able to determine the target spot's integrity parameters. For the case of the complete laser spot, there was the performance of the centroid calculation. Also, in situations where an incomplete laser spot reflected the target, there was the performance of invariant moments' operation. From the findings, the study indicated that from incomplete laser spot images, the laser spot's highest energy could be positioned precisely. The study also established that in order to establish the displacement amount, the image's center and the laser spot's highest energy could be overlapped.

Keywords--Convolutional neural network, deep learning, laser spot, machine vision.

1.INTRODUCTION

With a quick evolution in science and technology, there is a continuous decrease or reduction in material sizes or the Size of various parts of systems. To have the resultant miniature parts combined successfully, therefore, there is a growing need for the highest precision possible, a demand proving higher when compared the precision required when dealing with general parts [1, 2]. Also, while dealing with the miniature parts, especially in the context of mass system production, there is fixed production time for the respective parts [3]. Hence, in case of laser radiation offset that causes the junction's soldier to fail to have adequate energy absorbed, there might be failure in the weld [4]. Similarly, given some part, should the laser's high-energy zone irradiate other positions, there could be a direct rejection of the given

part [5]. The eventuality is that for the laser, there arises a need to have the highest energy zone searched and positioned [6].

For the majority of previous scholarly studies, the focus has been on the implementation of various hand-craft features. This usage has been informed by a quest towards representing the images' visual content, as well as the establishment of relevant measurements of similarity, achieving a similarity of low-level features and also ensuring that it (the similarity) is closer to that of high-level concepts [7]. When it comes to the deep convolutional learning technique, most studies document that it has steered improvements in the ability of feature extraction, implying that its implementation fosters efficiency when it comes to the measurement of similarity [7, 8]. In these studies, given a sample image, there was the extraction of its feature training classifier. Here, the neural network was used, a process that preceded the matching criterion. The eventuality is that there was the establishment of the input image's laser spot. There was also the searching of the center spot before moving the laser spot position to ensure that it overlapped the Charge-coupled Device (CCD) camera's image center. This overlapping process sought to ensure that the positioning criterion was completed. Important to note is that in situations where there was the use of large ranges of images, for incomplete spots, their images would often appear. As such, even though there was the realization of the spot re-imaging procedure's precise positioning, much time was consumed. Therefore, in the current investigation, the central purpose lay in the combination of a deep learning algorithm with machine vision. This combination sought to have a positioning system built, which could aid in the alignment of the center spot of the laser quickly and automatically.

When it comes to traditional techniques of template matching, it is worth remembering that they come with various defects. For instance, on each occasion that templates are changed, the techniques call for weight updating and continuous matching [9]. Important to highlight is that these defects waste a lot of time. Another problem with such techniques is that in situations where an area of the matched image and that of the template image are similar but they do not coincide with the target area, the resultant matching could be false [10]. Indeed, for imaging systems, they employ various parameters and databases. For the case of high-resolution images, they offer easy and precise position detections [11], yet, when it comes to contexts involving real-time systems, the computational costs associated with the high-resolution images are high [12]. To solve the recognition accuracy problem, some studies have proposed and advocated for the use of a hierarchical matching [13, 14], but these previously proposed schemes of classification do not come with all potential features. This failure is attributed to variability vastness regarding feature topology and geometry [15]. In this investigation, therefore, the main aim was to utilize or employ the deep learning technique for the purpose of enhancing feature recognition, as well as shortening the needed time for obtaining results. The motivation of the study was to remedy the aforementioned defects with which most of the previously proposed techniques have been associated.

2.METHODOLOGY

Notably, the purpose of template matching involves seeking parts of images that tend to match the given template image [3]. Initially, the read-in template images have their sizes and those of the matched images determined via calculation, with the outcomes stored. Should template images fail to divide exact the matched images, there is the supplementation of the bottom and right of the image by 0 [4]. In turn, there is the substitution of the image into a given model or algorithm. The role of this substitution process into the algorithm involves the determination of the template image's weight for the respective points within the matched image. With the maximum weight established, the upper left corner's position is determined relative to the matched image's template image. The next step involves inputting the template image's width and length. Given the matched image, then, there is the indication of the template image's region [16]. While numerous algorithms characterize the method of template matching [17], the current study relied on the case of the Sum of Squared Differences (SSD). It is also notable that the weight has to be calculated again for the respective matched images whenever the template is changed, which makes the process of template matching to consume a lot of time. Despite this limitation, however, there is considerably higher accuracy when compared to scenarios where the starting point search technique is employed [18-20]. Given this superiority, the template matching technique was employed in the current investigation.

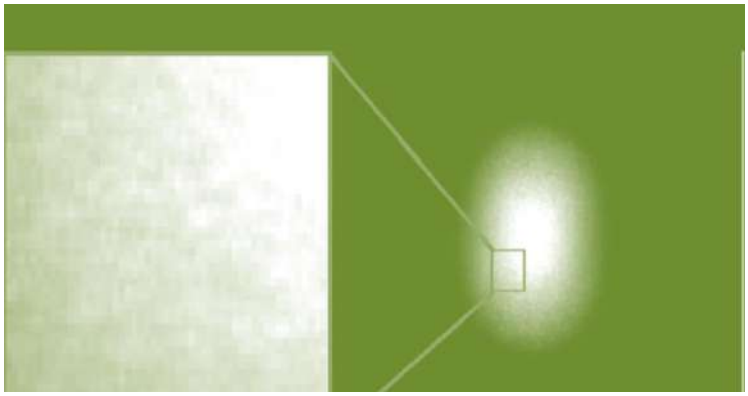

Fig.**1**.A sample template matching technique implementation outcome

To construct the central moment, the target area's centroid was selected and labeled as the center. The implication is that the calculation of the moment was the target area's point relative to the target area's centroid. Important to note is that the attribute did not exhibit any correlation with the target area's position. Rather, it exhibited translation invariance.

When it comes to the case of the convolutional neural network (CNN), it can be seen that a major difference that emerges between the traditional multilayer perception network and the CNN itself comes in terms of the pooling and convolutional layers [20]. For the latter layers, they allow for CNN's recognition of image details, yet other neural networks are known to be capable of only extracting data used in computation. For the CNN algorithm, its superiority is linked to three layers, which informed the model's adaptation in the current investigation.

One of the layers is the convolutional layer. Here, its purpose was to scan the picture. The scanning process would target the range from top to bottom via a filter that had a fixed size. The purpose of this procedure achieved via CNN's convolutional layer was to ensure that various local features were obtained. Indeed, these features formed the next layer's input. Following ReLU function processing, values that were less than 0 would be exported as 0. However, in situations where, following ReLU processing, values exceeded 0, they would be exported directly. The outcome reflected the perceived feature map. Also, in the feature map, the respective points could be deemed as the region's features in the original pattern, leading to their transmission to the layer that followed. For the CNN algorithm, therefore, the convolutional layer was used for the purpose of obtaining the pattern's local features. Given the entire convolution operation outputs, then, there would be their transformation by using a nonlinear activation function.

Important to note, however, is that for a previous layer and the same convolution layer, the convolution operation would share a common weight. From previous studies, it is notable that the use of traditional deep learning networks towards image processing and recognition would call for the splitting of the original two-dimensional picture to establish a one-dimensional image [9-11]. Here, individual pixels would be treated as eigenvalues and transferred to the DNN architecture to be analyzed [13]. The eventuality is that for the input pixels, there is the loss of original spatial arrangement data [16]. In this study, therefore, CNN' convolutional layer was useful because it allowed for the process of ensuring that the image's spatial arrangement was maintained and that the input feature was a partial image that was obtained.

Another CNN algorithm's layer that proved informative and informed the choice of the CNN model in this investigation entailed the pooling layer. Indeed, the pooling layer functions to ensure that there is the reduction of the size of the input picture. From some studies, this layer also allows for the reduction of the dimensionality of the respective feature maps [1], as well as the maintenance of crucial features [4]. Several merits are associated with the function of this layer of the CNN algorithm. For example, there is the reduction of over-fitting, the acceleration of system running, and the reduction of subsequent layers' associated parameters [18-22]. In the same fashion as the convolutional layer, also, the pooling layer relied on a filter for the purpose of having various operation regions' value extraction. Important to note is that the resultant output proved to be free from activate function.

The third CNN algorithm's layer was the full connected layer. Here, the layer reflected the general neural network. Thus, feature extraction was achieved by the convolutional layer and image parameter reduction achieved by the pooling layer, with the full connected layer receiving the feature information to engage in the classification process.

Indeed, there was the connection of the respective neurons to the given previous filter's pixel. For the respective connected weights, they were identical, allowing for their sharing in the same layer. However, it is also worth indicating that the respective connections exhibit unique and unrelated weights, implying that some considerable computing resources were likely to be consumed by the full connected layer. Whether this limitation was too minor to compromise the overall system efficiency and performance enhancement was a point of interest, which was clarified in the results and discussion section.

3. EXPERIMENTAL RESULTS AND DISCUSSION

With an image obtained by the CCD camera, with a given position in the image having the light spot established, there was the preliminary searching of the light spot image center's range. This process is demonstrated in the figure below.

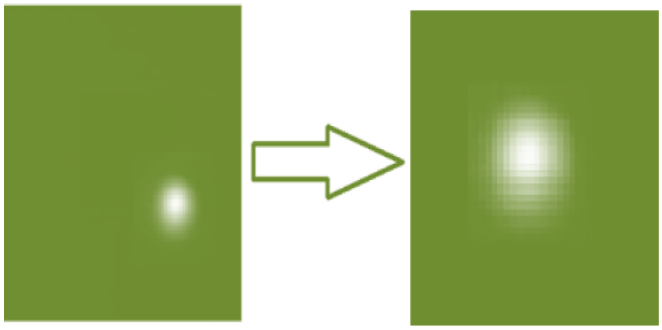

Fig.2. Preliminary searching of the light spot image center's range

After the program established the light spot's region, there was the displacement of the center point. This displacement led to the overlapping of the center of the CCD image, as well as an increase in the magnification of the CCD. Indeed, the increased magnification ensured that the CCD coincided with the light spot zone's size. In turn, there was the separation of the light spot zone, completing the first search.

As mentioned in the methodological section, searching for the laser spot zone was achieved via the system's utilization of a CNN. Given images that had various incomplete light spot modes and complete light spots, there was the training of the neural network. This training process sought to ensure that the program could judge or determine the image's light spot position rapidly and with considerable accuracy. Upon the successful positioning the light spot zone in a given image, given an initial part, the light spot zone's center was used as the center of the image. Here, there was deviation from the real center of the light spot, with the system treating the positioned laser spot zone as that which was not necessarily a complete light spot. At this stage, there was the measurement or determination of the distance between the light spot center and the center of the CCD image, allowing for the shifting and overlapping of the two centers.

Fig. 3. An illustration of the regional center image and the incomplete laser spot image.

In Figure 3 above, the regional center image did not reflect the center of the light spot, and it is presented alongside the incomplete laser spot image. The processing modes were two in this case. Also, regardless of whether the resulting light spot was incomplete or complete, it would be judged relative to the light spot zone's ratio. For the case of the complete light spot, there was the extraction of its centroid point, which was achieved via the centroid technique. In turn, there was the calculation of the distance between the light spot center and the center of the CCD image. The process would culminate into the movement of the center of the image to have it overlap the center of the light spot. In situations where the light spot was not complete, there was the calculation of the invariant moments relation to the image's incomplete light spot zone, eventually having it matched with the case of the preset light spot source image. The matching process sought to ensure that in the light spot, the centroid of the partial light spot zone had its position established. In turn, there was the calculation of the distance between the light spot center and the center of the CCD image, moving the image center to ensure that it overlapped the center of the light spot.

Given various sample numbers, the applied system's positioning effects were then described. To have the neural network trained, positive samples that were used were 100, 50, and 25. The following figure demonstrates the experimental results that were achieved via the use of 50 negative samples and 25 positive samples to have the neural network trained. From the figure, the implementation of the proposed program saw the complete light spot positioned successfully, but still, some misrecognition was experienced. Also, in the figure, it can be seen that there was no successful recognition of the incomplete light spot. To have the results improved while implementing the proposed system, it (the program) was trained again, and the sample number increased.

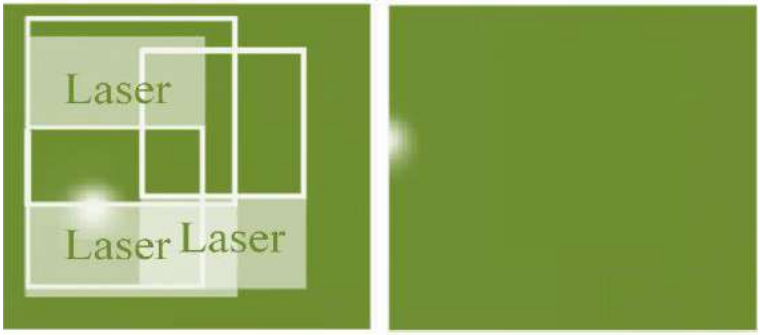

Fig. 4. The map positioning of the complete versus incomplete light spot for 25 positive samples.

The figure 4 above shows the results that were obtained after using 25 samples. As the study progressed, the focus shifted to the case of 100 negative samples and 50 positive samples, seeking to discern the behavior of the system, with those samples used for the purpose of neural network training. At this point, as it is highlighted in Figure 5 below, there was improvement in complete light spot misrecognition. However, it is important to note that still, the light spot region (only) could not be positioned. From the figure, it can also be seen that numerous misrecognitions were evident, but

incomplete light spots had their position recognized accordingly. To have the accuracy of the system improved, for a second time, there was the training of the network, with the sample number also increased.

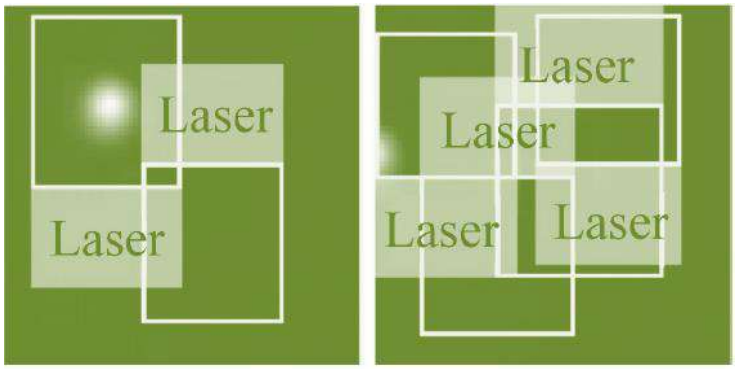

Fig. 5. The map positioning of complete and incomplete light spots.

The figure 5 above shows the results that were obtained after considering 50 positive samples. There was further training of the neural network, with 200 negative samples and 100 positive samples used. At this point, findings indicated the program's capability to have complete light spots' region positioned successfully. At this point, the study noted a marked reduction in the probability of the program's misrecognition. However, for incomplete light spots, they could still not be positioned.

For the three sample numbers that were used and the size of the feature region changed while having the neural networks trained, the table that follows shows the findings that were obtained. The motivation was to have 100 target images recognized. From the results, it can be seen that there was a significant increase in the accuracy relative to the sample number. For the case of the result candidates, they had misrecognitions and the corrected results. On the other hand, the target images' results minus the result candidates depicted the program's inability to have the number of targets recognized.

TABLE 1 . THE LIGHT SPOT POSITIONING SYSTEM'S EXPERIMENTAL RESULTS

Number of Positive Samples	25	50	100	100 (reduce feature region)
Number of Negative Samples	50	100	200	200
Number of Target Images	100	100	100	100
Result Candidates	74	90	96	98
Correct Results	40	69	88	96
Accuracy (%)	54.054	76.667	91.667	97.96
Classification Accuracy (μ)	0.37	0.284	0.245	0.14

From the table 1 above, it can be seen that still, there were some misrecognitions in the system. The outcomes could be attributed to the position that it was the same neural network that was used for the purpose of recognizing the incomplete light spots and complete light spots. Also, the results could be attributed to a situation in which it was only the partial zones that were positioned, even at a time when there were complete light spots. Similar, at the platform, when the laser was shot, there was a decrease in brightness outward in relation to the center spot of the laser, with particles in the air scattering the laser partially. It can also be inferred that due to the partial black regions'

brightness, visual recognition was likely to be difficult. With the bright zones' mode being closer to the light spot's sample, misrecognition was more likely to arise.

Given the outcomes that were obtained after implementing 100 positive samples, there was a successful determination of the complete light spot's region. From the case of the system flow, it was to the positioning regional center that the CCD image center was moved, eventually established as the template image. In turn, there was the calculation of the region's aspect ratio, as well as that of the template. The procedure saw the program's resulting template's aspect ratio stand at 1.027. With the identification of the complete light spot, there was the calculation of the template image's invariant moments, with the first moment then considered. Here, the light spot region's barycentric coordinates formed the first moment and are shown in the figure below.

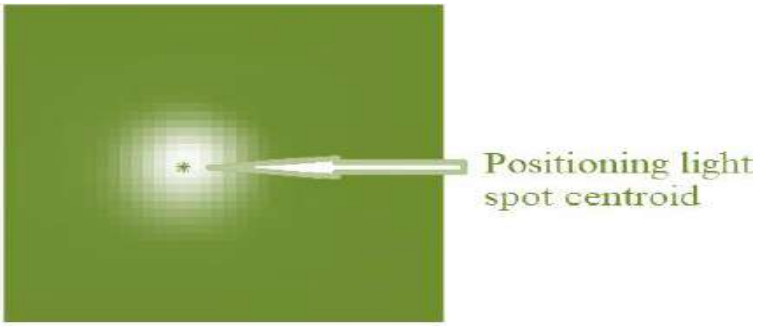

Fig. 6. Light spot centroid positioning.

In the culminating stage, there was the calculation of the distance between the center of the light spot and the center of the image, followed by the removal of the CCD camera. Here, there was the overlapping of the light spot center and the image center, allowing further for the second-time alignment of the light spot center. The figure below illustrates these procedures and experimental outcomes.

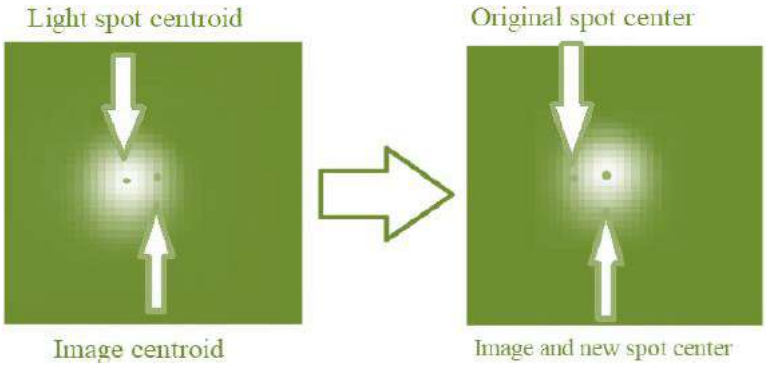

Fig. 7. An illustration of the second alignment.

For the laser spot, there was also the development of a gray level histogram. From Figure 8 below, it can be seen that the image center and the light spot center had their positions developed. Also, there was the establishment of the distance between both centers, achieved via coordinate relationship calculation.

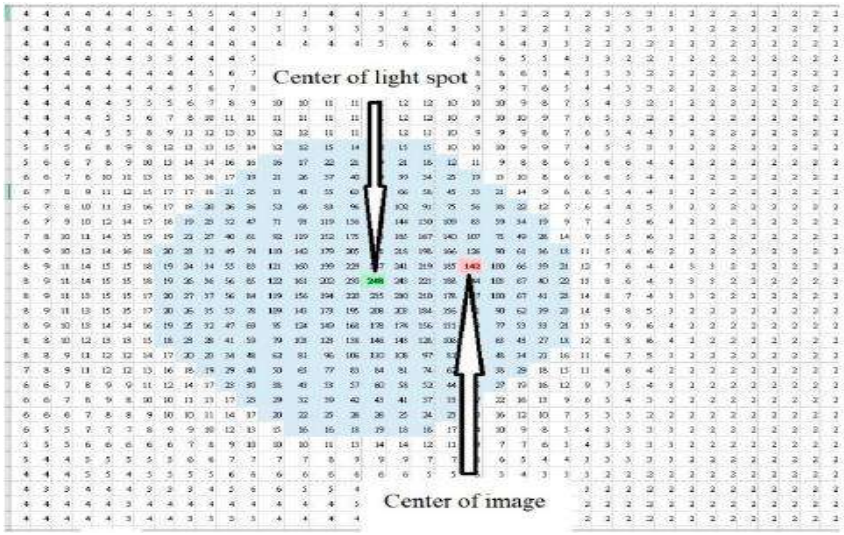

Fig. 8. Gray level histogram development for the complete light spot.

When it came to the mean errors concerning the established light spot center and the image center, they were calculated after the system conducted the process of positioning the light spot for various sample numbers. Here, 1 pixel was equal to 0.11micrometers. From the results, this study established that with an increase in the number of positive samples, there was enhancement in the features. Also, there was shorter time of the shift to the center of the light spot, with the first positioning' shift having its center get close to the light spot's center. The table below illustrates these findings.

TABLE 2 . SELECTED SAMPLE NUMBERS' RESULTANT LIGHT SPOT POSITIONING' MEAN ERRORS.

Number of Positive Samples	25	50	100	100 (reduce region)
Average Mis-distance (pixel)	3.367	2.579	2.224	1.273
Average Mis-distance (μm)	0.37	0.284	0.245	0.14
Detection Time (s)	0.5 ~1.6	0.5 ~1.6	0.5 ~1.6	0.5 ~1.6

After establishing the recognition region's invariant moments, there was the performance of the similarity matching process relative to the complete light spot's entire

points' invariant moment matrix. Here, the complete light spot's entire points had been obtained in advance. The process culminated into the exporting of the maximum matching weight's coordinate value. The following figure highlights these results.

Fig. 9. The weighting matrix of the invariant moment similarity.

From the findings demonstrated in Figure 9 above, given the complete light spot, the incomplete light spot had its position established. With the distance between the centroid of the complete light spot and the image center established, the CCD's position could be moved, with the search for the center spot also completed.

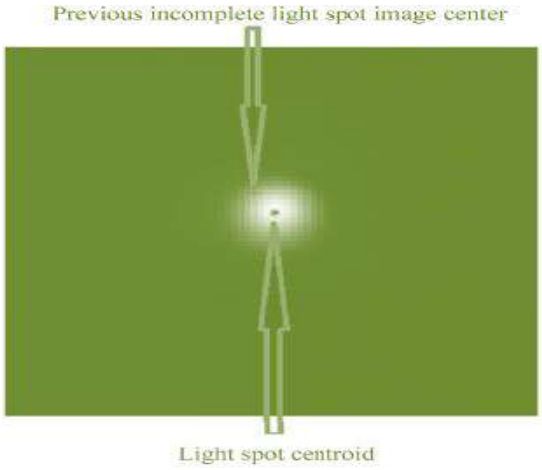

Fig. 10. An illustration of the light spot centroid and the image center of the incomplete light spot's relative positions.

In an industry such as the healthcare sector, it is worth noting that the devices used to acquire images have undergone tremendous advancement. Due to this progress, the resultant data has become so large that the attribute of big data has evolved. Indeed, these paradigm shifts make it interesting and challenging when it comes to the practices of image processing and analysis. With the marked growth in medical modalities and images, there has been a demand for medical experts to embrace extensive efforts, yet they have remained prone to human errors, with large variations also likely to be reported across various experts. As such, techniques of machine learning have been embraced, aimed at having diagnosis processes automated. Despite these efforts, it remains notable that the case of traditional machine learning techniques holds that they do not exhibit adequate levels of sufficiency, especially in situations involving complex problems. With machine learning and high performance computing combined, therefore, big medical image data can be handled adequately, yielding more effective and accurate diagnoses. This study's results have demonstrated that apart from aiding in feature selection and extraction, deep learning exhibits the ability to construct new features. Also, deep learning is seen to promise to stretch beyond aiding in disease diagnosis and steer improvements in the

measurement of predictive targets, having offered actionable predictive algorithms that efficiently support the work of physicians.

Another trend that this study has established is that for diseases to be diagnosed more accurately, aspects of image acquisition and interpretation play an informative role. In the last few years, there have been substantial improvements in the nature of devices of image acquisition, especially in relation to radiological images that exhibit higher resolution. Some of them include MRI, CT, and X-Ray scans. In the wake of these images, this study has given insight into the role of image processing technology in yielding automated image interpretation. Through deep learning, neural network algorithms are seen to gain application. For example, this study's proposed system is deemed insightful and applicable to healthcare practical situations because its superiority in performance is confirmed when compared to traditional techniques, allowing for the identification of indicators such as those of tumors for the case of MRI scans, as well as cancer in blood. With more hidden layers, deep learning has been found in this study to improve on artificial neural network (ANN), whereby it offers higher levels of abstraction, as well as marked improvements in the process of image analysis. here, some of the additional practical scenarios to which this study's findings lend themselves include medical imaging, face recognition, speech recognition, and object detection.

The current study has established further that deep neural networks, relative to image processing, play a crucial role because of their capacity to have various layers of neurons stacked hierarchically. The proposed system, in particular, is seen to conform to and reflect this merit because of its capacity to form hierarchical feature representations. Also, the proposed system's gigantic modeling capacity implies that through deep neural networks, all potential image mappings could be memorized, coming after successful trainings with adequately large knowledge database. At this point, it can be inferred, therefore, that this study's results are contributory to the current state-of-the-art, whereby it allows for the making of intelligent decisions such as the extrapolation and interpolation of cases that could be otherwise unseen. Also, the proposed system is seen to point out the critical manner in which a major impact is generated in relation to medical imaging, as well as computer vision. With the system also projected to gain application to situations such as those involving voice and text processing, the convolutional neural network that is used simply points out how deep learning algorithms play a critical role relative to image processing at the industry level.

In this study, another trend that is worth acknowledging is that the performance of CNN was compared to that which had been reported previously in other experimental studies. For the CNN algorithm, it can be observed that the resultant drawback with which it tends to be associated is that it demands a lot of labeled data before achieving the image classification role – for the case of image processing. However, its positive side, as established in this study, is that it comes with very good performance and that the model learning process is fast. Another notable point concerning the CNN algorithm was found to hold that it exhibits superior performance when applied in contexts involving two-dimensional data, especially because it comes with convolutional filters that could allow for two-dimensional transformation into three-dimensional systems or architectures. For the case of the deep neural network (DNN) with which CNN was compared, its positive side is documented to come in the form of its wide usage due to great accuracy [2]. However, the DNN model also exhibits drawbacks, whereby the process of system training is not trivial [11]. This drawback is attributed to the observation that there is the propagation of the error back to a previous layer, with the model's learning process also deemed much slow.

Previous studies have also focused on and documented the nature and performance of the recurrent neural network (RNN). For this algorithm, it is worth indicating that it exhibits the capacity to learn certain image sequences, sharing loads across all neurons and steps [3]. For this case of the RNN model, with many variations in existence, it is notable that there arise possible state-of-the-art accuracies when it comes to the aspect of image recognition and processing. However, when compared to the case of the CNN algorithm that was utilized in the current study, the RNN model exhibits many issues because of the need for big datasets, with additional limitation reported in terms of RNN-associated state of gradient vanishing. A question that arises here is the manner in which, in the future, the CNN algorithm, which was used in this study, could be tailored in a manner that incorporates positive performance aspects with which the other comparative models come while countering its associated demerit documented earlier.

4. CONCLUSION

When the concept of center spot search is considered, this study established that the matching process via the utilization of invariant moments tends to be faster when compared to situations involving the use of ordinary template matching. Here, the study demonstrated that when invariant moments are used, they allow for image digitization. At some

moment, the information that needed to be processed was about 72% less than the case involving the use of images for the operation of template matching. Also, for the source image's every point, there was advance calculation of the invariant moment, which was then saved in a database, with the matched region's invariant moments also having been calculated. In turn, there was the calculation of the similarity to the database on the focus. From the findings, it was discerned that in situations involving template matching, a weighting matrix has to be generated as the matching process progresses. Also, the process calls for the creation of the weighting matrix each time there is a change of the template, eventually consuming considerable or vast amounts of time. In relation to the proposed system, this study established that it relies on the ratio aspect when it comes to the checking of whether or not the target light spot is complete. With the nature of the light spot's complete image aiding in or determining the selection of the positioning method, the proposed system demonstrated that for all images, the perceived complex computation is not required. Overall, the proposed system translated into significant reductions in the overall system's load. In the future, there is a need for further research or scholarly studies to focus on the behavior of the proposed system in environments that stretch beyond the image processing aspect and entail voice and text processing or recognition. Indeed, whether the proposed system's perceived superiority in the image processing context might be felt and prove consistent when it comes to voice and text recognition and processing should be the focus of future studies, upon which inferences and conclusions might be made regarding the extent to which the model might contribute to the current and future state-of-the-art in feature recognition and processing.
